Theatre Lighting in Russia.—The Odessa Theatre has recently been supplied with electric light by means of Zipernowski transformers. The current is brought from a central station at a distance of over a mile. The work has been carried out by M. Ganz and Co., of Buda-Pesth. The same firm has recently lit the Riga Theatre.

The Telephone in Italy.—The following statistics are derived from an official source, and are brought down to a recent date. The telephone is now in use in 49 towns in Italy, the total number of subscribers to exchanges amounts to 9,600, in addition to which there are 470 private lines. The Government derives from this source a revenue of 171,000 lire per annum.

Fire Alarms at Barcelona.—A correspondent writes from Barcelona :—"It may be of interest to you to know that Messrs. Spagnoletti and Crookes, of London, have acquired the contract for fitting up the whole of the extensive buildings for the forthcoming Barcelona Exhibition with their patent electrical fire alarms, which at the close of the Exhibition will be adopted and applied throughout the city."

Messrs. Gent and Co's. Price List.—This list of "general electrical accessories" is prefaced by some very useful and practical instructions for the erection and maintenance of electric and pneumatic bells, including details of wiring (with diagrams) and the management of batteries, &c. The catalogue and price list is very fully illustrated, and the information given is more detailed and more useful throughout than is generally to be found in publications of this class.

Suakim.—The Eastern Telegraph Company's repairing ship "John Pender" reported "all well" at Suakim when she repaired the cable, which was broken about 100 miles from that place on the evening of the 14th. For a few hours the cable worked perfectly, but singularly enough it broke again on the morning of the 15th, about 100 miles further on. The "John Pender" will proceed at once to repair it, and another of the company's ships—the "Mirror"—is to-day at Suez on her way to Suakim.

Paris Exhibition, 1889 (British Electrical Section).—We desire to remind intending exhibitors of the meeting which has been convened by the Council of the Society of Telegraph-Engineers and Electricians for Monday next, the 19th inst., at 3 p.m., at the Institution of Civil Engineers, 25, Great George-street. We understand that Mr. J. Aylmer, the Society's Honorary Secretary for France, will attend the meeting, in order to afford any detailed information required.

The Paris-Brussels Line.—The attempts of the authorities at Brussels to effect communication between the Paris trunk lines and their ordinary subscribers by means of translators do not appear to have been successful. It has now been officially notified that those subscribers who wish to take advantage of the Paris line may have a wire return established (instead of the present earth return) on payment of an annual charge, which will not in any case exceed 50 per cent. beyond the rental at present paid.

Telegraphic Communication Interrupted.—The severe storm of Sunday last made its effects felt throughout the country. Telegraphic communication was interrupted in many places, and at noon on Monday the Post Office gave notice of delay on messages to Exeter and all western offices beyond, and also both to the Channel Islands and South Wales. At a later hour of the same day the postal telegraph authorities were, however, able to issue a notification cancelling the notice of delay previously given.

Trades Unionism.—We have received the following from Messrs. R. E. Crompton and Co. :—"Messrs. Crompton have been informed that it is the intention of the Trade Union not to allow piecework to be introduced into any of the new trades such as they consider electrical engineering to be, and under these circumstances the Company have no option but to part with such of their men who are members of the union. The affair is one of considerable interest to the whole of the electrical engineering trade."

Sales of Plant.—We would call the attention of our readers to two important sales of electrical plant, which are announced in our advertising columns for the following week. On Mon-

Digitized by Google

day next Messrs. Wheatley Kirk, Price and Goulty will sell the surplus plant of the Elieson Electric Company, who are moving their works to their locomotive station. On the following Wednesday a large stock of primary batteries will be disposed of. This last sale offers a chance to amateurs and others which should not be missed.

Tubular Magnets.—In the last issue of the *Bulletin de la Société Belge d'Electricien* M. Ernest Gérard has a note on tubular magnets. He points out that if a ring of soft iron of the same section as the magnet itself be laid on the top of the tube, so as to be in contact all round, it is held less firmly than is the case when it merely stands on edge, although in the latter case contact is made at only a single point. M. Gérard thinks that this result can be explained by considering the distribution of the lines of force in the field.

Multiple Synchronous Telegraphy.—In the year 1875 M. R. Kœnig constructed a variable tuning fork which could be adjusted to different rates of vibration. This was effected by making both the stem and the prongs of the fork hollow, the stem terminating in a closed vessel containing mercury. By means of a piston the mercury could be forced up into the hollow of the fork, and thus diminish its rate of vibration. This principle M. Neeren proposes to employ for the adjustment of the vibrating reeds employed in synchronous telegraphy. He has constructed an instrument on these lines which seems to have been successful.

Theatre Lighting by Gas Companies in France. — At Clermont-Ferrand the gas company has just completed an installation of electric light in the theatre of that town. Motive power is furnished by a 16 horse-power Otto gas engine; an Edison dynamo and a set of accumulators are employed. The total number of lamps is only 130.—At Beziers the gas company has also undertaken to light the theatre by electricity.—At Montpellier the Municipal Council has applied to the gas company to supply electric light for the theatre, but the parties were unable to agree upon terms. Negotiations are now in progress with M. Popp.

A New Thermo-Electric Element.—*L'Electricien* says that M. Heimel has constructed a new thermo-electric element having an E.M.F. of 0·18 volt, with an internal resistance of 0·009 ohm. Our contemporary does not say what metals have been employed nor at what difference of temperature the E.M.F. has been obtained. We give for comparison the E.M.F. *per degree centigrade* of the following metals as determined by Latimer Clark:—Clamond's alloy (antimony and zinc) and iron, 0·0102 volt; antimony and bismuth, 0·0102 volt; German silver and iron, 0·0102 volt; platinum and iron, 0·0011 volt; copper and iron, 0·0006 volt.

Lighting of ss. "City of New York."—An important addition will shortly be made to the fleet of Transatlantic liners by the launch of two new vessels built by Messrs. Thompson for the Inman Company. The first of these is to be named the "City of New York," and is to be launched during the present week. In point of size, safety, and comfort this vessel will surpass anything at present afloat. The electric lighting installation is also, we believe, the most extensive ever placed on ship-board. The total number of incandescent lamps exceeds 1,000, and both engines and dynamos are duplicated. The work has been carried out by Messrs. King, Brown and Co., of Edinburgh.

The Barcelona Exhibition.—At the request of the Secretary of State for Foreign Affairs, the Society of Arts has undertaken to promote the interests of the exhibition in this country, and to act as the intermediary between British exhibitors and the executive of the exhibition. The exhibition is announced to be opened on the 9th April, and the date for the receipt of applications from foreign exhibitors has already passed. A request for an extension of the time has been made to the Spanish Executive. In the meantime, British manufacturers who wish to take part in the exhibition, and have not already sent in applications for space, may apply to the Secretary of the Society of Arts, John-street, Adelphi, W.C.

The Lighting of the City.—At the last meeting of the Commissioners of Sewers Mr. H. H. Bridgman submitted a report from the Streets Committee, recommending that the proposed contract with the Brush Company should not be further proceeded with. He explained that it was not intended to shelve the question of lighting the City by electricity, but it had been decided to consider the proposals brought up at the last meeting of the Commission as to other companies doing the lighting cheaper. Mr. J. C. Bell protested strongly against the report of the committee. The report, was, however, adopted, Mr. Bridgman assuring the Commissioners that no time would be lost in bringing further propositions before the board.

Kensington.—At the last meeting of the Kensington Vestry a communication was read from the secretary of the Notting Hill Electric Lighting Company, inquiring whether it is probable that the vestry will shortly notify their assent to the undertaking of the company, as they feel sure that not only their undertaking, but the residents in the district generally, will be prejudiced by delay; also from the Kensington Court Electric Lighting Company, calling attention to the serious prejudice caused to the company by the delay in dealing with their application for powers to lay underground mains through an extended area in this parish, that it may be notified with the least possible delay, especially as the whole question has still to be reviewed by the Board of Trade.

Gas and Electric Lighting at Glossop.—At a meeting of the General Purposes Committee of the Glossop Town Council, held last week, Mr. Herbert Rhodes replied to a statement made at the last meeting of the Council, during the discussion on the purchase of the gasworks, with reference to the adoption of the electric light at some of the local mills. The firm he represented put 1,400 electric lamps into their mills in 1886; and these gave so much satisfaction that in 1887 they put in another 1,000. Two other local manufacturers had adopted the electric light; and though corporations ought to own gas and water works, he considered that under these circumstances it would be the height of folly to entertain the idea of purchasing the gasworks. The mayor (Alderman Sidebottom) said he quite agreed with these remarks.

The Berlin Telegraph Office.—Friday last will long be remembered, says *The Times*, as the busiest day on record at the central telegraph office of Berlin. The pressure was great on Thursday, when 29,878 telegrams, aggregating 799,926 words, had to be sent off. But this record was eclipsed by the following day, no fewer than 36,615 telegrams, containing together 1,115,551 words, being despatched to all parts of the globe, and in different languages. All the Government telegraphists fit for duty had to be called in to meet the pressure, and all the available instruments were worked. It was a fortunate circumstance that the Berlin Bourse was closed, as this enabled the authorities to make use of the instruments there for the work. During the busiest hours of Friday last no fewer than 346 telegraphists were at work at the same time in the great instrument room of the central telegraph office, and 230 instruments were operated.

The Snowstorm in America.—On Monday last a snowstorm of unprecedented severity, and lasting until Tuesday noon, or even later, occurred in New York, and extended as far as Boston and Philadelphia, doing immense damage to property, and blocking railway and vehicular traffic almost completely. The fall of snow, which was accompanied by a blizzard, has destroyed a great portion of the telegraph system in the districts we have named, and probably in other places as well, to which all telegraphic communication is for the present interrupted. Overhead wires, both of the telegraphs and the electric light, are lying broken in the streets of New York, buried beneath the snow; and it is already estimated that the Western Union Telegraph Company's system will suffer by this catastrophe to the extent of nearly a million dollars. The breakdown has given rise to one of the most curious telegraphic "dodges" ever recorded. Communication between New York and Boston has been maintained *via* London.

Godalming.—A meeting of the inhabitants of Godalming was held in the Masonic Hall, Godalming, on Tuesday, the 6th inst., to consider the proposal of the Equitable Telephone Association (Limited), of 75, Queen Victoria-street, E.C., to establish a telephone exchange in Godalming and district. The Mayor (Alderman Stedman), in the unavoidable absence of the Vicar (The Hon. and Rev. Canon Brodrick), presided, and after the meeting had been addressed by Mr. A. A. Campbell Swinton and Mr. Macpherson Grant, of the Equitable Telephone Association, the following resolution was moved by Mr. E. Pullman, of Godalming, and on being seconded by Mr. E. Stedman was put to the meeting, and declared by the chairman to be carried *nem. con.*:—"This meeting considers it, in order to keep with the times, desirable to establish a telephone exchange in Godalming if a sufficient number of subscribers can be enlisted." The Swinton telephone instruments were fitted up for the occasion in connection with the hall, so that before they dispersed the visitors had an opportunity of testing them practically.

The Indian Telegraph Department.—*Indian Engineering* says:—"In the resolution published in October last, Government professed a sincere desire to clear the block in the Telegraph Department by facilitating the retirement of the senior officers on special pensions. The profession may have been sincere; but it is already tolerably certain that the Government scheme for clearing the block is not likely to effect its purpose. The resolution laid down that all officers who had eighteen years' service in October last would have the privilege of retiring on special pensions provided they did so before the 1st April next. Unfortunately, many of these officers will have nearly but not quite completed twenty years' service on the date named, so that were they to retire they would, though gaining the special pension, lose the full ordinary pension for which they had nearly qualified. It seems hard that many of the officers in the department should be placed in the dilemma of having to choose between giving up their full twenty years' pension, and losing the special pension granted under the resolution."

Watt's Electrolytic Zinc Process.—This process has lately been submitted to a series of practical trials at the works of the Gülcher Electric Light Company at Battersea, and seems to have proved to be completely successful. An important feature in this process is that while the metal is deposited in a perfectly reguline form, unaccompanied by those crystalline growths of the metal termed "treeing," there is, it is said, literally no evolution of hydrogen at the cathodes, so that polarisation from this cause cannot occur, while there is also no waste of energy from this source. It is stated that the cost of the electrolytic reduction by this process, as compared with the ordinary smelting process, shows a considerable advantage in favour of the former; and while in the process of smelting there is a loss of from 15 to 20 per cent. of metal, by the new process there is practically no appreciable loss. Another significant feature in the Watt process is that ores of low grade can be treated which could not be economically dealt with by the smelter. A company is now being formed to carry out Mr. Watt's zinc process on an extensive scale.

Royal Meteorological Society.—Ninth Annual Exhibition of Instruments.—At the ordinary meeting of the society, to be held by permission of the Council of the Institution of Civil Engineers, at 25, Great George-street, Westminster, on Wednesday, the 21st inst., at 7 p.m., an address will be delivered by the President, Dr. W. Marcet, M.D., F.R.S., "On Atmospheric Electricity," illustrated by experiments; after which Mr. G. J. Symons, F.R.S., will make a short communication "On the Non-existence of Thunderbolts; Elucidated by Accounts of Searches after Them, and the Exhibition of Specimens." The meeting will then be adjourned, in order to afford the Fellows and their friends an opportunity of inspecting the exhibition of apparatus connected with atmospheric electricity, including lightning conductors, photographs of lightning, and damaged objects, and of such new instruments as have been invented and first constructed since the last exhibition. The exhibition will, at the request of the Secretary of the Institution of Civil Engineers, be open in readiness for their meeting on Tuesday evening, the 20th inst., and will remain open till Friday, the 23rd inst.

Obituary.—We regret to record the death of Mr. William Pryor Binney. Mr. Binney was a Nova Scotian by birth, and was the son of the Right Rev. H. Binney, Bishop of Nova Scotia. He commenced his career as a telegraphist in March, 1858, when he went out to the Levant, and has been since that time connected with the Levant submarine cable systems, which were acquired by the Eastern Telegraph Company in June, 1872, and he was then appointed their divisional manager. Mr. Binney died at Syra on Monday night, the 12th inst., and was buried with military honours at that place on the following day. His funeral was attended by the Governor of the Cyclades and the Consular body acting as pall bearers, and also by the civil, military, naval, and ecclesiastical authorities of the island, as well as a numerous *cortége* of sympathising friends, the Burial Service being performed by the Rev. R. Guinet. Mr. Binney was appointed British Consul in the Islands of the Greek Archipelago in September, 1874, which post he held to the day of his lamented death. Mr. Binney had the personal esteem of all the directors and staff at head-quarters, and the company have to regret the loss of a valuable and energetic servant. He was a man of great ability in many directions, rendering conspicuous service in the repairing of cables, in the conduct of negotiations, and as an electrician; in fact, doing well anything to which he chose to turn his hand.

Volunteer Corps of Submarine Miners.—Speaking in the House of Commons on the 9th inst. on the Naval and Military Estimates, Mr. Stanhope said:—"The great mercantile ports of the country were also bound to be remembered. There was a desire in all these ports to raise, for the service of the country, submarine mining corps, which were so urgently required for the protection of those ports. The Government had included provision for raising all the corps in the proposals they now made for carrying out submarine mining, and they had also added whatever sums would be

Digitized by Google

required for light armaments for protecting such submarine miners. He knew that was not all that was wanted, but the Government had left it in that way because they wanted to induce the localities to come forward and co-operate with the Government for their own defence (cheers). If they desired to see increased defences, they should come and meet the Government, and tell them what they would do in the way of contribution. He could say for the Government that if the inhabitants of those mercantile ports would do that, the Government would be prepared to meet them, and he was most anxious that no time should be lost in providing for them such defences as were adequate to their needs (cheers). They should do all they could for the defence of these ports as quickly as they could, and he had asked those who were most responsible for advising him in carrying out these defences how quickly they could be completed."

Contract Open for the Lighting of Havre.—The Municipal Council of Havre has issued a circular, of which the following is a translation :—"The Municipality of Havre is prepared to authorise, for a period of six years, an Electric Lighting Company, to establish in the said town a central station, and to lay down in the public streets such conductors, cables, and wires as are necessary to serve the following streets and places :—Rue de Paris, Place Gambetta, Place de l'Hôtel-de-Ville, Rue Thiers (so far as the Rue du Champ de Foire), Rue des Drapiers, Rue Royale. The conduits and cables are to be placed underground, and must be perfectly insulated. They will be subject to the regulations of the Streets Committee. The lighting will comprise, in the districts named above, both private lighting, incandescent lamps, and public lighting, either by arcs or by incandescents. The authorisation will confer no monopoly, and a fixed scale of charges must be agreed on. Under these conditions, the Municipality is prepared to consider communications and propositions from such companies, and would particularly direct their attention to the following points :—(1) At what rate will they be prepared to undertake private lighting? (2) Will they also undertake public lighting? And at what rate? (The tariff should be given both in terms of lamp-hours and by meter.) (3) What annual royalty will they offer to to the municipality? Communications should be addressed to M. A. Rispal, à la Mairie du Havre, before the 31st March."

Liverpool.—The *Liverpool Courier* of Tuesday, March 13th, contains the following :—"In 1883 the Liverpool Electrical Supply Company (Limited) was formed, apparently as a sort of tentative effort to give the electric light a permanent local home. The experiment has succeeded. The original capital was £10,000, but the business expanded and the capital was increased to double that amount, and it will be seen that at the meeting yesterday the directors agreed upon a dividend of 7 per cent. This circumstance suggests that there is not only a demand for the electric light, but that this demand can be met with substantial profit to the shareholders. Under these circumstances, it is not surprising to note that the company have decided to make their business more commensurate with the requirements of the city. To this end they are increasing their capital to £200,000, including the shares to the value of £20,000 already subscribed, and they intend to supply the electric light to all who seek it within a very wide area, comprising the more important residential parts of Liverpool, as well as the great business centres. It is arranged also that the supply shall be by day and night at a regular fixed charge, measured by meter. There has been a supply station in Rose-street for four years, and a second station has recently been started in Tithebarn-street, while a third and more important one is approaching completion in Harrington-street. Besides the use of electricity as an illuminant it is naturally expected that its utility as a motor will become more generally recognised when it is brought within reach of those who need "power" for trade or other purposes. There is one circumstance that must secure for the company's prospectus a careful consideration on the part of the public; the ten-fold enlargement of the undertaking is promoted by responsible Liverpool gentlemen who are fortified by the experience already gained. With a capital of £10,000 the dividends were 5 per cent., while with a doubled capital the dividends have reached 7 per cent., a fact which seems to indicate that proportionately larger profits may be expected from the further extension of the business. The enterprise is of importance to the whole community, and not merely to the investing portion of it, and its development will be watched with considerable interest."

Marking an Era.—An American journal, writing on the New York Electric Club, says :—"The opening of this Club has marked an era. It has marked various other things, but principally an era. You can tell a member of the Electric Club the moment you meet him, for he, like the era, is marked. The doors of the club are so arranged that the moment you press a button the door will fly open. The projectors forgot that somebody might be on the other side of the door, and the consequence is that hardly a member has escaped being knocked down by a suddenly opening door. There is hardly a nose in the club which is not more or less out of repair. The electrical foot warmer has been a success, but the same cannot be said for the boot-blacking arrangement. One of the members got it started and forgot the combination. Before it could be hauled off it had used up a nice pair of shoes, had ruined the stockings and was polishing off his toes when help arrived. Still, taking it all round, the electrical institution has more than fulfilled the anticipations of its projectors. This being the case Detroit capitalists have put their heads and their cash together and have resolved to establish an electric restaurant, which is sure to be a great success. The plans, which we have carefully examined, promise something absolutely unique in the way of restaurants. There will be no waiters, no cashier, no cook, nothing, in fact, that a food consumer usually sees in an eating house, and consequently there will be an entire absence of many aggravating accompaniments to a meal which have been endured simply because it is against the law to slaughter a waiter when he most deserves it. The way it will work is this: A man sits himself down at a table and picks up the bill of fare. The price of every article is marked. He puts a fifty-cent piece in the electrical machine and gets fifty cents back in five-cent bits. Steak, say, is twenty-five cents. He drops five of the coins in the slit beside the steak button, presses the latter and the steak is turned on below. An indicator shows how the cooking advances, the dial being marked from 'very rare' to 'cinder.' At the proper moment he presses the delivery button and the steak comes up through a trap door on the table. In a similar manner the guest calls for potatoes, bread, butter, coffee, and all the rest, taking care to drop the necessary number of nickels into the slits beside the respective buttons. When he finishes his meal he rings as he would at a telephone when he is through talking. Then a man at the central office turns on a current and the dishes disappear, leaving the table ready for the next comer. The Electrical Restaurant Company (Limited) will have a central office with engines, dynamos, &c. They will establish restaurants at various parts of the town, and it is expected that the fact that they will have no waiters will alone given them a handsome profit. Thus electricity has learned to 'labour and to wait,' as the poet puts it."

ELECTRICAL APPLIANCES USED WITH TORPEDOES AND SUBMARINE MINES.

BY CAPTAIN C. A. M'EVOY.

(Concluded from page 470.)

(Concluded from page 470.)

SPAR OR OUTRIGGER TORPEDO (DUPLEX SYSTEM).

The spar torpedo is employed as an offensive weapon. It is carried at the end of a spar attached to the bow or side of a steam launch, and is fired electrically, either by contact with the vessel attacked, or at will by the operator in the launch. In Fig. 4 is seen a section of the apparatus. In front is carried

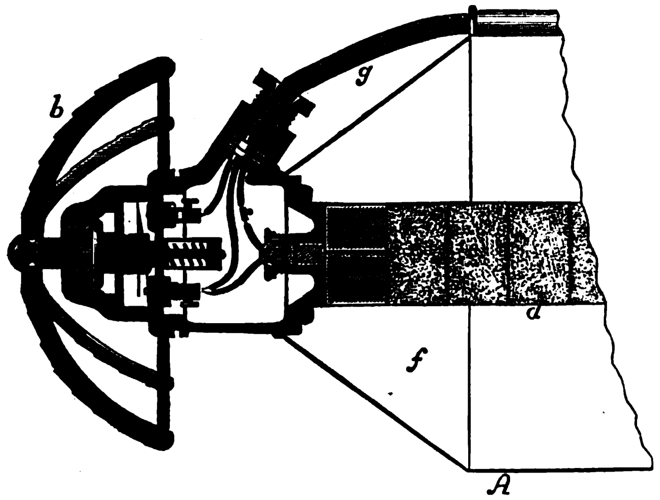

FIG. 4 shows a section of the front interior of the spar torpedo. A. Outer case of torpedo. *b*. Rocking contact maker. *c*. Fuse. *d*. Primary case. *e*. Gun cotton discs. *f*. Space for main charge. *g*. Electric cable.

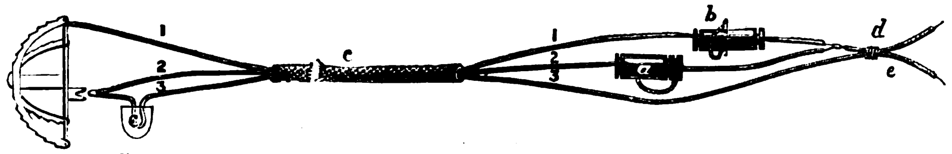

FIG. 5 (diagrammatic) shows the means of firing the spar torpedo and controlling the same from the launch. *a*. Firing key. *b*. Disconnector for controlling the contact firing. *c*. Triple-cored cable. *d* and *e*. Wires leading to battery.

a rocker provided with teeth or notches for making firm contact with the sides of an enemy's vessel. When pressed forcibly either backwards or sideways, the rocker moves inwards and closes an electrical contact, which fires the charge. The torpedo may also be fired at will without the aid of the rocker. The connections by which either of these ends may be accomplished

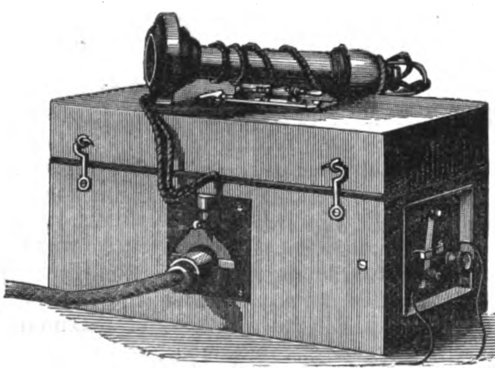

FIG. 6.

are shown in the diagram Fig. 5. *a* and *b* are plug switches; when *b* is closed the fuse can be fired by the rocking contact maker, the circuit being completed through wires 1 and 3; but when *a* is closed the fuse is immediately fired electrically through wires 2 and 3.

SUBMARINE DETECTOR.

This apparatus is employed for finding the positions of torpedoes or mines, lost anchors, chains, &c. It is practically a Hughes induction balance, and consists of a portable box (Fig. 6), having in it a magneto-interrupter, or make-and-break arrangement, and two coils of equal resistance. One of the coils is connected with the terminals of a primary battery, the other coil is in a secondary circuit with a telephone—a length of flexible cable, having four conductors in it, and at one of its

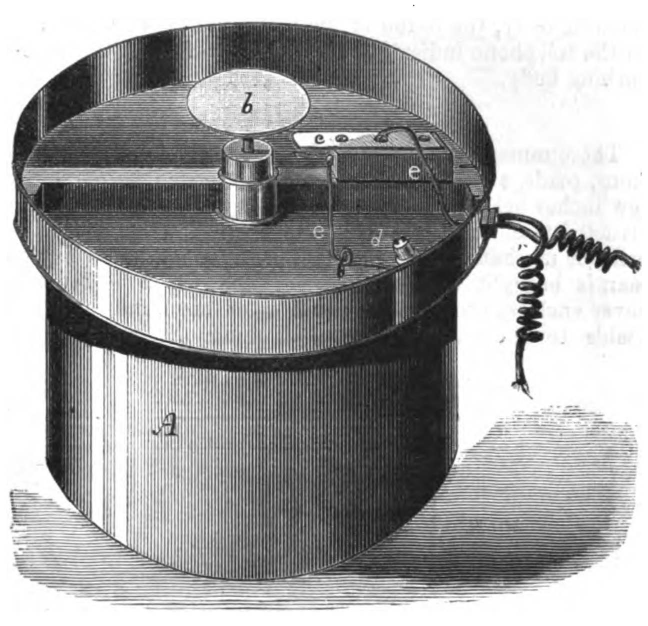

FIG. 9 shows a land mine with its cover removed, and its firing mechanism exposed. A. The body of the mine. *b*. Firing spindle. *cc*. Electric contacts. *d*. Electric fuse. *e*. Insulated wires from battery.

ends a flat box called a sounder (Fig. 7). This sounder contains two coils of the same resistance as those in the portable box, one

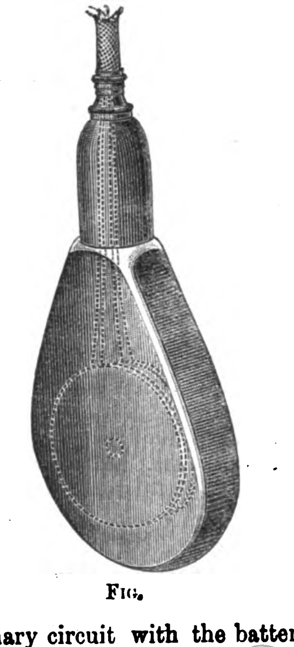

FIG.

being in the primary circuit with the battery, and the other in the secondary circuit with the telephone. The other end

Digitized by Google

of the flexible cable is provided with terminal connections for attaching to the portable box. When it is attached and the battery in action, the primary and secondary circuits will be complete through the cable and coils, and the make and break of the interrupter may be heard in the telephone.

An adjustable screw arrangement in the portable box enables the coils to be fixed at the proper distance apart to secure a perfect balance between the coils in the primary and secondary circuits. When the coils are adjusted so that the make and break cannot be heard in the telephone the instrument is ready for use. If the sounder is then brought near a metallic body, the sound of the make and break will be heard in the telephone indicating the presence of a metallic or disturbing body.

LAND MINES.

These mines are employed for the defence of fortified positions, roads, and camps. They are intended to be placed a few inches below the surface of the ground, and are so constructed that they are watertight, and fire themselves electrically or mechanically when the pressure of the weight of a man is brought to bear upon them. A thin metal top or cover encloses the firing mechanism of the mine. This cover yields to the pressure brought upon the mine, and the plunger seen in the illustration (Fig. 9) is depressed, closing an electrical contact, and either giving a signal or else actually firing the mine, the connection being practically the same as already described for submarine mines.

The arrangement for firing the mine mechanically when trodden on is of a novel character. It is desired to cause the pressure, however gradually applied, to deliver a sharp blow upon the detonator. This is accomplished in the following way:—A spiral spring, which is compressed by the descent of the plunger, is fixed at the lower end to a block of metal sliding loosely in an outer tube. This block is held in position in the tube by a thin wire which is threaded through a hole in the side of the tube, and in the block itself. Under the pressure of the plunger the wire first elongates, and then breaks suddenly, allowing the compressed spring to thrust the block sharply down on the detonating cap. Thus the firing of the mine is assured, however gradually the pressure may be applied.

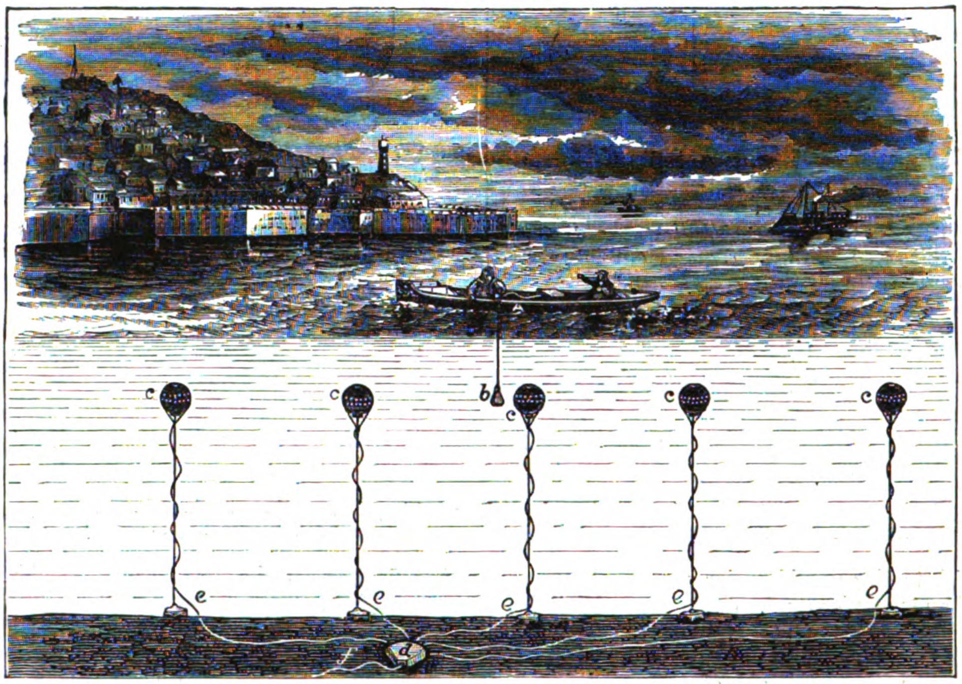

FIG. 8 shows the submarine detector sounder being lowered from an electric launch for the purpose of discovering the presence and position of mines in a harbour. *a*. Electric launch. *b*. Detector sounder, suspended from launch. *ccccc*. Submarine mines. *d*. Junction box. *eeeee*. Single-cored cable connecting junction box with mines. *f*. Main cable to shore.

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

(Continued from page 406.)

The current equation, expressing the current strength in terms of the impressed electromotive force, the resistance, inductance, and phase angles, which holds good when a circuit of constant inductance and no sensible capacity is subjected to moderately great pulsations of electromotive force, has been in previous pages arrived at algebraically from first principles. It is, however, possible to elucidate its meaning by geometrical methods. Let a circular disc (*see* Fig. 22) be pivoted at the centre O, and at any point P on the circumference let a plummet line be attached. In front of the circle is a fixed horizontal line XX^1. Let the disc move round counter-clockwise at a uniform rate, the time of one revolution being T. As the disc goes round, the length of plummet line PM above XX^1 fluctuates. Since PM = OP sin POM, it follows that if the magnitude of PM be taken at small equal intervals of time during one revolution, and such heights be plotted off as off-sets at equal distances above and below a datum line, the extremities of these ordinates will lie on a simple periodic or sine curve. In other words, PM grows and shrinks in height in accordance with a simple periodic law. We can, therefore, represent any quantity which fluctuates in magnitude according to a simple sine law of growth by representing it as the projection of a point on the circumference of a circle revolving uniformly, taken on a horizontal or vertical fixed line drawn through the centre. Hence, if OP represent the maximum value of an electromotive force fluctuating periodically, PM will represent its various magnitudes during the complete period. The magnitude of PM at any instant is known when we know OP, which is called the *amplitude* or maximum value, and POM the *phase angle* of the motion.

On such a diagram let a radius be drawn to any scale representing by its vertical projection the periodic fluctuation of an impressed electromotive force varying according to a single sine law, and acting on a circuit of given inductance and resistance with a fixed periodicity; the problem is to draw on the same diagram another radius of which the vertical projection shall represent the actual current strength in

the circuit at the corresponding instant. The impressed electromotive force at any instant balances, or is equal to, the sum of two others, viz., the effective electromotive force driving the current, which is equal to the product of the ohmic resistance of the circuit and the current at that instant in it, and the inductive or counter-electromotive force, which is equal to the rate of variation of the flux of force or number of lines of force traversing the circuit. The phases, or times of maximum, of these two components are not identical.

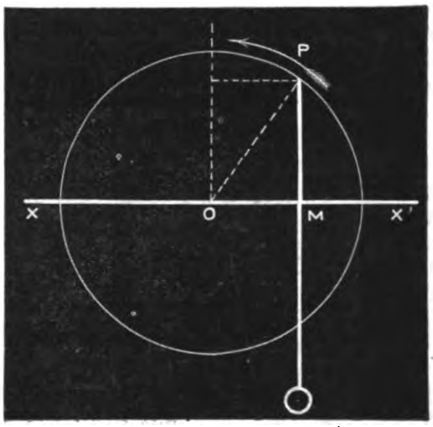

Fig. 22.

They differ by 90°, since the effective electromotive force has the same phase as the actual current, and the inductive electromotive force, depending on the rate of variation of the current, comes to a maximum at the instant when the current is zero or is changing sign.

By the proposition on p. 286, *ante*, these two periodic quantities can therefore be represented by sine curves, one of which is shifted backward relatively to the other, so that the crest of the wave of one coincides with the hollow of the wave of the other. We shall first proceed to show that the sum of two simple periodic motions of the same periodic time, but different phases and amplitudes, will, when added together, produce a simple periodic motion of the same periodic time.

Let a parallelogram of cardboard, O A B C (Fig. 23), be cut out and pivoted by a pin at the angle O, so as to turn freely clockhand-wise. Let a vertical line, O Y, be drawn through O, and in any position let the sides O A, O C, A B be projected

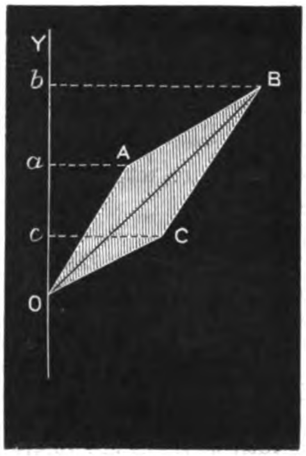

Fig. 23.

on to O Y. The projection of lines equal and equally inclined are equal; hence, since A B is equal and parallel to O C, the projection of A B—viz., ab—is equal to that of O C—viz., O c. But O b = O a + ab always for any position of the card; hence O b = O a + O c. The projection of the diagonal is therefore equal to the sum of the projections of the adjacent sides. As the card moves uniformly round, the magnitudes of the projections fluctuate at each instant, according to a simple periodic law. Hence the sum of the simple periodic motions of which O A, O C are the amplitudes, and which have a fixed difference of phase represented by the angle A O C, is the simple periodic motion represented by O B in amplitude and relative phase. If, then, a point be subjected to two simultaneous simple periodic motions of given amplitudes, and of which the phases differ by 90°, the actual motion will be represented, as to amplitude and phase, by the diagonal of the parallelogram of which these two form the adjacent sides. Returning in thought to electric motion, consider the motion of a *particle of electricity* (if we may be

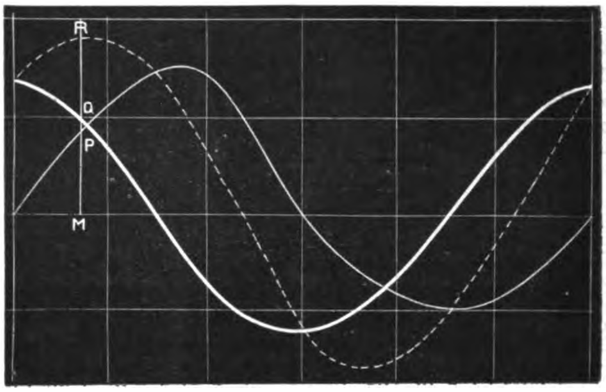

Fig. 24.

allowed the expression) in the wire subjected to two simultaneous simple periodic motions of unequal amplitude and fixed difference of phase equal to 90°. The displacement at any instant due to the two together is equal to the sum of each separately. If the individual motions are represented by the vertical projections of two lines, O A, O B, fixed like hands of a toy clock at right angles (Fig. 24), the resultant motion is that indicated by the projection of the diagonal O C on the same vertical. We have seen (*see* p. 286) that, if the variation of a quantity is represented by a simple sine curve, the variation of its *rate of change* is represented by a sine curve of different amplitude shifted backwards by 90° of phase, or by a quarter of a wave length. It follows from this proposition that if we add together at every instant the motions or the ordinates representing them on a diagram of two simple periodic motions, one of which is the curve representing the rate of change of the ordinate of the other, we shall get a new sine curve, of which the maximum value falls between that of the other two, and of which the amplitude is different, but wave length or periodic time the same. In Fig. 25 the thick white line sine curve represents one wave of a simple periodic motion. The fine white continuous line is a sine curve of equal wave

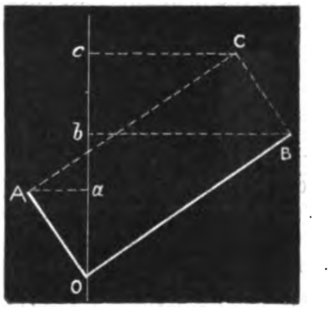

Fig. 25.

length, of which the ordinate P M at any point represents or is proportional to the rate of change of the ordinate Q M of the thick curve at the same instant. Adding together the ordinates of the thick and thin curves, we get a new dotted line sine curve, of which the ordinate R M is equal to Q M + rate of change of Q M. If we substitute for the sine curve diagram a clockhand diagram (*see* Fig. 24), then the projection of O B, viz., O b, corresponds to the ordinate Q M of the black curve; that of O A, viz., O a, corresponds to P M, the

Digitized by Google

ordinate of the thin curve; and that of O C the diagonal of the rectangle, O A, O B, corresponds to R M, and is the resultant of the motion O B, and the rate of change of that motion, viz., O A. If, then, O B represents the amplitude or maximum value of the actual periodic current in a circuit, a line, O A, drawn at right angles to O B, will represent to a suitable scale the rate of change of that current.

We are, then, led also to this converse proposition, that we can resolve any simple periodic curve into a pair of component periodic curves of equal periodic time, but of which the maximum value happens for one before, and for one after, that of the original. It is, then, not difficult to see that the geometrical construction necessary is as follows. Let a unit of length be taken to represent a volt, an ohm, an ampere, and a unit of self-induction equal to an earth quadrant or 10^9 centimetres.* Describe a circle whose radius is numerically equal to the maximum value of the impressed electromotive force (*see* Fig. 26). Draw any radius O P to represent the amplitude E of this impressed E.M.F. If, then, the angle P O X is represented by pt, the value of the vertical projection of O P, viz., P M, is $E \sin pt$, and is therefore the instantaneous impressed E.M.F. corresponding to the phase pt. On O P describe a semicircle, and set off O Q, making an angle P O Q with O P, such that the tangent of P O Q is equal to the ratio Lp to R. Where R is the ohmic resistance of the circuit, and Lp is equal to 2π times, the quotient of the inductance of the circuit by the periodic time of the impressed E.M.F., or time of one complete alternation. Join P Q and draw O W parallel to and equal to P Q. If I represents the maximum value of the current, and i its instantaneous value corresponding

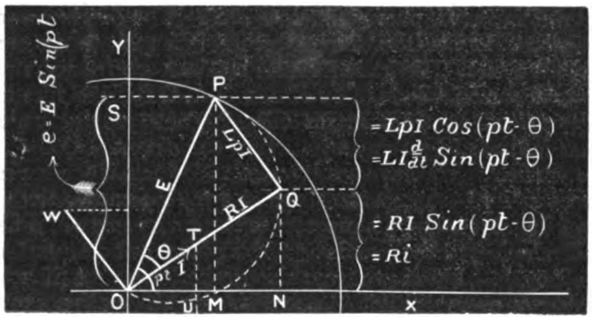

FIG. 26.

to the instant when its phase has certain value $pt - \theta$, we know that $i = I \sin (pt - \theta)$, and the rate of change of the current at that instant is then $\frac{di}{dt} = p I \cos (pt - \theta)$. The ratio of the maximum value of R i to L $\frac{di}{dt}$ is therefore R I to LpI, or R to Lp; but R i is the instantaneous effective electromotive force driving the current, and L $\frac{di}{dt}$ is the corresponding counter electromotive force of self-induction at the same instant, and the sum of these two is the impressed electromotive force at that instant. Consider the two lines O Q and O W, the ratio of their magnitudes is R to Lp by construction, and the sum of their vertical projections is equal to the vertical projection of O P—that is, to the instantaneous impressed electromotive force. Hence these lines O Q and O W satisfy the conditions requisite for being the representation of the maximum effective and inductive electromotive forces respectively on the same scale and relative phase as that on which the line O P represents the maximum impressed electromotive force, and O Q therefore represents in magnitude the value of RI and O W that of Lp I, and the angular positions of these with respect to O P represent the relative phases of the effective, inductive and impressed electromotive forces.

* The unit of self-induction, whose value is an earth quadrant or 10^9 centimetres, has not yet been formally christened. Profs. Ayrton and Perry have called it a *secohm*, and Mr. Oliver Heaviside has proposed, I believe, to call it a *Mac* (after Maxwell). Not to introduce further confusion, we may tentatively adopt the former.

One R^{th} part of O Q is then the magnitude of the maximum current, and its phase of maximum value is behind that of O P by an angle θ. If O T = one R^{th} part of O Q, O T represents the maximum current, and T U, the vertical projection, represents the magnitude of the current in the circuit at the instant when the impressed electromotive force has the value P M.

The respectively varying current and impressed E.M.F. will be graphically represented by the variation of T U and P M as O P and O T move round the circle in equal times, separated from each other by a constant angle of lag P O T = θ. It will be seen that whilst O Q is equal in magnitude to the product of the true or ohmic resistance of the circuit and the maximum current that O W or P Q is equal to the product of Lp and the maximum current. Hence we may call Lp the *inductive resistance* of the circuit, because it is a quantity of like dimensions to the true or ohmic resistance. The angle of lag of the current is therefore an angle of which the tangent is the ratio of the inductive to the ohmic resistance.

If we draw a right angle triangle (Fig. 27), of which the base represents the ohmic resistance of the circuit and the perpendicular the inductive resistance, then the hypotheneuse represents the quality $\sqrt{R^2 + L^2 p^2}$, which has been called the impedance. The angle of lag may therefore be defined thus

$$\text{tangent of angle of lag} = \frac{\text{inductive resistance of circuit}}{\text{ohmic resistance of circuit}},$$

or

$$\text{cosine of angle of lag} = \frac{\text{ohmic resistance of circuit}}{\text{impedance of circuit}}.$$

In order to carry out the construction in Fig. 26 we require to know either $\tan \theta$ or $\cos \theta$. The latter is most easily

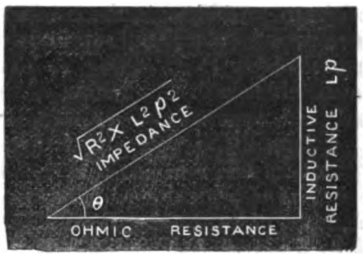

FIG. 27.

determined. The experimental determination of this quantity will be dealt with in due course.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER VIII.—*The Calibration of Current Indicators.*

(Continued from page 478.)

89. *Explanation of Fig. 53.*—The relation between currents and angular deflections up to 28 degrees on the standard horizontal indicator of the General Post Office (illustrated in Fig. 54) is shown by Fig. 53. This is seen to be practically a straight line—that is, the instrument is practically a proportional one up to about 28 degrees. It should be noticed, however, that on closer examination the line is not absolutely straight, although very nearly so, but is tending to bend round slightly. This may be noticed by putting the edge of a flat rule along the line, and seeing how far the direction of the line coincides with the straight edge of the rule, which in this case exactly coincides from 0 to 15 degrees, the remainder of the line up to 28 degrees being very slightly removed in direction from this portion. The readings for this instrument were taken in the same way as the last, except that only one cell was used, the E.M.F. of which was 1·868 volt. It will also be observed that the currents, which are very small, and are measured in millionths of an ampere, or micro-amperes, produce sensibly

Digitized by Google

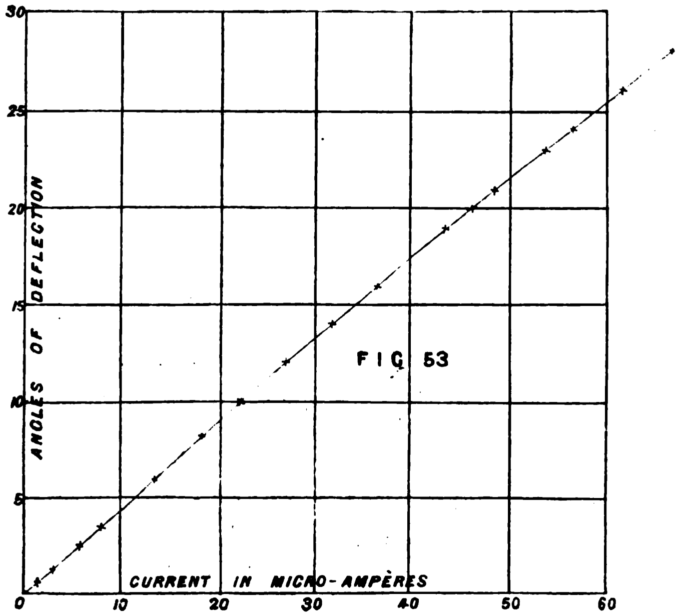
large deflections, which means that the instrument will give perceptible indications when it is circuited with very high resistances and a low E.M.F. For instance, with the single cell used above, it was necessary to insert one megohm (one million ohms) resistance in circuit with the instrument, in order to get the lowest deflection, viz.: about $\frac{7}{10}$ths of a degree. The current producing this deflection would be, in amperes, the

$$\frac{\text{E.M.F.}}{\text{total resistance}} = \frac{1{\cdot}868 \text{ volt}}{1 \text{ megohm} + 800 \text{ ohms}}.$$

We may, however, neglect the resistance of the instrument (800 ohms) when added to so large a resistance as one million ohms, and multiplying the current in amperes by one million to reduce it to micro-amperes, we have

$$\frac{1{\cdot}868}{10^6} \times 10^6 = 1{\cdot}8 \text{ micro-ampere},$$

causing the above perceptible deflection. This shows that the instrument is capable of measuring very large resistances.



90. *Comparison of Instruments by their Figure of Merit.*—Comparing the calibration curves of these instruments will show at once that the same current produces a different deflection on each. This difference is due to the construction of the instrument, the controlling force on the needle, the kind of pivoting or suspension of the needle, and the number of turns of wire on the coils. As a basis of comparison between instruments differing in these respects, we have to determine for each instrument what is termed its *Figure of Merit*, which is simply the total amount of resistance in ohms (including the instrument coil resistance) through which, with one volt E.M.F., a deflection of 1 degree or division is produced. Now, by Ohm's law, this resistance will be equal to

$$\frac{1 \text{ volt}}{\text{current producing 1 degree deflection}},$$

which is the same thing as the *reciprocal of the current in amperes producing 1 degree deflection*, and it is by these words that the figure of merit is usually defined. Hence, an instrument with a high figure of merit is one which will show a perceptible deflection with a very small current.

The figure of merit may be found from the calibration curve by taking any current on the *fi st straight portion* of the curve—that is, the portion of it which is proportional, and observing what deflection this corresponds to; then dividing the current by the number of degrees deflection we have the current for 1 degree, the reciprocal of which, after reducing to amperes, is the figure of merit. Taking Fig. 53 we find by inspection that 12 degrees deflection is produced by 27 micro-amperes; and therefore 1 degree would be produced by $\frac{27}{12}$ $= 2\frac{1}{4}$ micro-amperes, which is equal to $\frac{2\frac{1}{4}}{10^6}$ amperes.

The figure of merit is therefore the reciprocal of this current in amperes, and is

$$\frac{10^6}{2\frac{1}{4}} = 10^6 \times \frac{4}{9}.$$

Now, by inspection of the straight portion of the curve for the astatic instrument in Fig. 52, we find that 18 degrees deflection is produced by 0·1 milliampere, or 100 micro-amperes; and therefore $\frac{100}{18}$ micro-amperes, or $\frac{100}{18 \times 10^6}$ amperes, would give 1 degree deflection. The figure of merit is then the reciprocal of this, which is

$$10^6 \times \frac{18}{100}.$$

If the two instruments are now compared by their figures of merit we have

$$\frac{\text{suspended needle instrument}}{\text{pivoted needle instrument}} = \frac{10^6 \times \frac{18}{100}}{10^6 \times \frac{4}{9}} = \frac{81}{200},$$

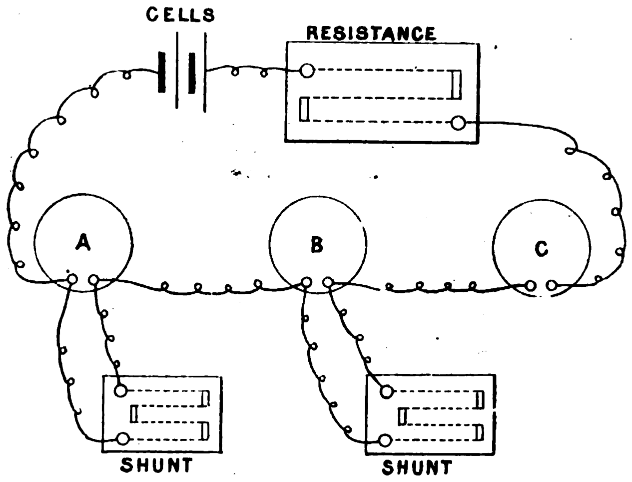


Fig. 54.

that is, the figure of merit of the pivoted needle instrument is $2\frac{1}{2}$ times that of the other, which is the same thing as saying that the astatic instrument requires $2\frac{1}{2}$ times as much current as the pivoted needle instrument for a deflection of 1 degree. If the curve is not determined, the figure of merit may be easily found by passing a weak current through the instrument only sufficient to move the needle a few degrees, say 5; for the reason that mostly all instruments read proportionally to the current for the first few degrees. The figure of merit is then simply *this deflection divided by the number of amperes producing it.*

91. *The Simultaneous Calibration of Instruments of Similar Sensitiveness.*—The calibration of two or three instruments may conveniently be effected at the same time by connecting them together in "series" (para. 40) with a cell or two and an adjustable resistance box (para. 86) in circuit. Whatever current, then, passes through one instrument passes through all, so that, proceeding in the same manner as for one instrument, and supposing, in the first instance, that the instruments are all of the same type, we should expect to obtain somewhere about the same deflection on each for every current passed through. The number of cells would be arranged to give a large deflection on each indicator when no resistance was unplugged in the box, and the successive readings would then be taken by increasing the resistance unplugged, until the deflections became very small.

The current for every change in the resistance in circuit would be, by Ohm's law, the

Digitized by Google

$$\frac{\text{E.M.F. of battery}}{\text{total resistance in circuit}},$$

where the total resistance is the sum of the resistances of the coils of the instruments added to that of the cells (if appreciable) and the resistance unplugged in the box. It is advisable for facility in calculating the currents to make every resistance unplugged in the box of such an amount that, added to the resistances permanently in circuit, the total number of ohms for each current becomes a multiple of ten.

The deflections of the needles of each instrument are read off every time a change is made in the current strength, and from these readings curves are plotted for each instrument as previously described.

92. *The Simultaneous Calibration of Instruments differing in Sensitiveness.*—It more frequently occurs, however, in practice that the instruments are dissimilar as regards their sensitiveness. A glance at the curves of the three instruments which have already been considered will show that any given current produces different deflections on each, or, what is the same thing, different currents are required by each instrument to produce a given deflection. For example, taking 25 degrees deflection on each instrument, the curve in Fig. 48 shows that the vertical indicator requires 15 milli-amperes of current for this; the astatic instrument curve (Fig. 52) shows that 120 micro-amperes are required, and the horizontal pivoted needle instrument curve (Fig. 53) shows that about 60 micro-amperes would give this deflection. The latter instrument produces the deflection with the weakest current, and therefore is the most sensitive, the vertical detector being the least sensitive. Now, if three instruments of different degrees of senitiveness were joined together in series and a current sent through sufficient to cause a maximum deflection on the *most* sensitive instrument, the deflections on the less sensitive indicators would be too small to commence with, and therefore by some means the sensitiveness of the instruments must be equalised so as to produce about maximum deflections on each to start with.

(To be continued.)

REVIEWS.

Le Wattmetre et son Maniement. (Ganz and Co., Buda-Pesth.)

This is a little treatise of 17 pages devoted to the consideration of a wattmeter designed and manufactured by the well-known firm of Ganz and Co., of Buda-Pesth. The instrument consists of a movable-coil dynamometer, in which the fine wire coil has very few turns, but is placed in series with a non-inductive resistance. This is the arrangement employed by Dr. Fleming to measure the efficiency of the Zipernowski transformer in the year 1884; it has also been used by Prof. Ayrton, and was spoken of several times during the recent discussion on transformers by the Society of Telegraph-Engineers and Electricians. The instrument is admittedly a convenient one, if only the accuracy of its indications could be relied on. We will return to this point presently.

Judging from the description before us, the instrument, as made by Messrs. Ganz and Co., is all that could be desired as regards mechanical design and finish. The non-inductive resistance is enclosed in a separate box, and suitable plugging and switching arrangements for dealing with high potential difference are provided. Careful instructions are laid down as to the precautions which are necessary to be observed when handling the apparatus under such circumstances, and on these and other matters of detail the pamphlet gives evidence of competent knowledge, and is of a thoroughly practical and useful character.

Returning now to the question of the degree of accuracy of which the apparatus is capable we find that the authors have made an assumption which is not by any means an unnatural one as a first shot, though we are sorry to believe that it will not stand further investigation. They assume that the instrumental coefficient may be expressed by the ratio of the resistance r, of the fine wire branch, to its impedance $\{r^2 + (2\,n\,\pi\,L)^2\}^{\frac{1}{2}}$. In order to show that this ratio is in general closely approximate to unity they give the following numerical illustration as one in which conditions unfavourable to the wattmeter have been chosen:—

Let the resistance $r = 250$ ohms
„ inductance $L = 0{\cdot}02$
Let $2\,n$* $= 200$

Then we shall have $\dfrac{\{r^2 + (2\,n\pi L)^2\}^{\frac{1}{2}}}{r} = \sqrt{\dfrac{62628}{62500}}$, a number differing very little from unity.

It will be noted that the coefficient so obtained is not a constant, because it contains n, the number of alternations per second. This, however, would be a trifling difficulty, supposing the ratio in question to be a true measure of the accuracy of the indications. Unfortunately this does not seem to be the case.

Prof. Ayrton has recently pointed out that not merely is the current through the fine wire coil of a wattmeter diminished on account of the self-induction of this coil, which tends to make the wattmeter reading too low, but that in consequence of the alteration of phase of the current in this coil there is, in addition, another error, which tends to make the wattmeter reading too high, so that, in fact, the actual error is due to the *combination* of these two errors, and he has given the following expression (see *Electrician*, Feb. 24, 1888, page 421) for the coefficient K, by which the readings of the wattmeter of this type must be divided to obtain the true watts:—

$$K = \frac{r}{r'} \times \frac{\tau^2\,r\,r' + \pi^2\,L\,L'}{\tau^2\,r^2 + \pi^2\,L^2};$$

where τ is the time of an alternation $\left(= \frac{1}{2n}\right)$. r is the resistance of the fine wire circuit, and L its coefficient of inductance, while r' and L' are the corresponding terms for the circuit in which the power given is to be measured.

We may write this

$$K = \frac{r^2\,r' + 4\,n^2\,\pi^2\,L\,L'}{r^2\,r' + 4\,n^2\,\pi^2\,L^2},$$

which equals unity only when $L = L'$ or when $L = 0$. It is worth noting also that the instrument may indicate either more or less than the true watts according as $L' > L$ or $L' < L$. From this it appears that the object sought by Messrs. Ganz cannot be attained by merely reducing the inductance of the movable coil to a minimum. If L be small, we may say that approximately

$$K = 1 + \frac{4\,n^2\,\pi^2}{r^2\,r'}\,L\,L',$$

from which it will be seen that K is also greater than unity—that is, the wattmeter always reads too high if L be small. Hence the correction that Messrs. Ganz have taken into account is not only of less importance than the correction arising from the alteration of phase of the current in the fine wire coil, but is actually a correction in the *wrong direction.*

It will be worth while to see how a numerical illustration will work out. Taking the figures supplied in the pamphlet $r = 250$, $L = 0{\cdot}02$, $P = 2\,n = 200$, then we shall have

$$K = \frac{62500\,r' + 7896\,L'}{62500\,r' + 157}.$$

If L' be greater than 0·02, then unless r' be very large compared with L', K will be larger than unity—that is to say, the instrument will read too high. If the wattmeter be used to measure the power given to a transformer we might easily have such values as

$$r' = 5; \qquad L' = 20,$$

in which case

$$K = 1{\cdot}5,$$

or the readings are 50 per cent. too high.

* $2\,n\,\pi$ is now usually written p, and Dr. Fleming proposes to call it a *pulse* or *pulsation* (see *Electrician*, Feb. 24, 1888, p. 404).

Pott's Mining Register and Directory for the Coal and Ironstone Trades of Great Britain and Ireland. 1888. (London: Simpkin, Marshall and Co.)

This is the first appearance of a volume which it is intended to issue annually and which cannot fail to be of great value to those interested in the important industries with which it is concerned. The contents are well arranged, and its value is enhanced by a series of geological maps reprinted by permission from "Hull's Coal Fields of Great Britain." In the next issue we have no doubt that the editor will find it necessary to insert a section dealing with the electric light in mines, and probably also with electric pumping and haulage. Meanwhile we may add that the printing and get-up of the book are excellent.

NUMBERING CONDUCTORS.

SYSTEM USED BY THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.

The denominating numbers of conductors supplied by the Brush Corporation are equal to the number of thousandths of a square inch contained in the section of copper. This denominating number indicates, therefore,

a. How many amperes the wires should carry.
b. How many 65-volt. lamps may be fed by it (approx.).
c. When multiplied by 4, the number of yards to $\frac{1}{10}$ ohm.
d. When multiplied by 4, the weight in lbs. of 1,000ft.

Letters following the denominating numbers indicate the quality of insulation, thus:—

B. Bare.
C. Covered.
D. Drywork insulation.
E. Ship insulation.
F. High tension insulation.

No. 25D is a wire suitable for ordinary house work; it will carry 25 amperes, its weight is $4 \times 25 = 100$lb. per 100ft.; $4 \times 25 = 100$ yards have a resistance of $\frac{1}{10}$ ohm.

On this system—

No. 1 is equal to No. 20 B.W.G.
No. 2 " " 18 "
No. 3 " " 16 "

When it is desired to arrange conductors for any specified fall of potential between the dynamo and lamps, the size of the wire may be obtained by the following formula $N = \frac{LC}{40E}$, that is to say, the required size of conductor is obtained by multiplying the length in yards by the current in amperes, and dividing by 40 times the specified fall in volts.

With the normal current of one ampere per thousandth of a square inch, the fall in volts is equal to $2\frac{1}{2}$ per cent. of the number of yards of conductor in circuit.

(This last is right for copper of $97\frac{1}{2}$ per cent. conductivity.)

(In "*d*" the weight per 1,000ft. comes out 4 per cent. heavy.)

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

THE ELECTRICIANS' DIRECTORY.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

NOW READY.

Volume XIX. of "The Electrician," strongly bound in cloth, is NOW READY, price Ten Shillings and Sixpence.

Cases for binding "The Electrician," price Two Shillings, Now Ready.

CONTENTS OF THE CURRENT NUMBER.

THE TELEGRAPHS OF THE EMPIRE.

That papers read before the Royal Colonial Institute should be pitched in a high key of patriotic fervour is matter neither for wonderment nor regret. But there are in these days two kinds of patriots—the one who loves his country, respects its institutions, and desires to establish them on the firmest basis; the other who, under the pretence of a superior devotion, vilifies and belittles his countrymen for the purpose of riding any pet hobby of his own which he cannot induce them to mount. Mr. HENNIKER HEATON may not belong to the latter class, but assuredly the paper which he read on Tuesday night answers the description pretty exactly; and it is not our fault if we are compelled to regard him as the exponent of a parochial rather than an imperial sentiment in his treatment of a subject which he claims to have spent the best years of his life in studying. Some of the grosser exaggerations of his paper were exposed in the discussion which followed, notably by Sir JAMES ANDERSON, who had an easy task in demolishing some of the misleading statistics and still more misleading concealments with which the paper abounded. We cannot do more than deal with the general scope of Mr. HEATON'S recommendations and the grounds upon which he asks us to believe that he has based them. Asks us to believe, we say, because, although the grandiloquent language which adorned the address was calculated to impress an audience with the loftiest sense of his object, a calm perusal of his arguments will leave no doubt in any impartial mind that the author speaks as a colonialist, and exclusively in the interests of the particular colony which he represents.

To establish this point we need go no further than direct attention to the magnificent way in which he sets aside all considerations of prudence, of cost to the mother country, and of sacrifice on the part of English capitalists, when advocating a Pacific cable to connect the Australian Colonies with the Canadian land lines at Vancouver. Feasible or not feasible, such an enterprise would be extremely hazardous; confessedly it would require to be heavily subsidised; it would inflict serious injury on the existing lines over the Eastern route, and would in no way help those 240 millions of British subjects in India whom Mr. HEATON treats as Australasian colonists when it happens to square with his argument. But his

Digitized by Google

attitude becomes still plainer when we examine Mr. HEATON'S proposals in detail. The Government—the British Government, be it understood—are to buy up the Eastern Extension Cable Company, and become virtual masters of the projected cable in the Pacific. Reasons for this selection are not far to seek under the mist of rhetoric with which Mr. HEATON veils his real object. By this means the Australian Colonies would be relieved of the subsidy they pay to the Eastern Extension Company. This is evidently one object; and, except to gratify a spite—which he does not attempt to conceal—against the Eastern Company, it would appear to be the main object, for no sooner is the Government in possession of the Eastern Extension cables than the Pacific cable is to be laid to compete with it—an arrangement advantageous no doubt for the Colonies of Australasia, but not particularly inviting for the home Government.

Of the strain of lofty benevolence which runs through Mr. HEATON'S paper we have already expressed a profound distrust; but our suspicions are more than confirmed by the frank avowal of his expectations with regard to the effect of his scheme on the future of the company which was the great pioneer of cable enterprise to the East. When speaking of Government purchase Mr. HEATON is in a highly moral vein. "Faith must be kept, and the dictates of honour must be obeyed. If we are to destroy the monopoly which has grown up, let us proceed by just and honourable means." But when it comes to the application of these virtuous monitions, Mr. HEATON is for buying up the Eastern Extension and leaving the Eastern to take care of itself, or, to put it plainly, to bring that company to its knees by the pressure of an overwhelming competition. Sir JAMES ANDERSON, who represented the offending company on Tuesday evening, was apparently in no way alarmed by these ill-considered threats; nor do we see any reason for his being so. We are now more confident than ever, after Mr. HENNIKER HEATON has said his worst, that the British Government will not yield to his enticements. Almost equally certain is it that Australian money will not be found to further the quixotic venture of a Pacific cable; and the more it is discussed the less likely is it to find favour with the English investing public.

In the opening passages of his paper Mr. HEATON eloquently set forth what may be described as the text of his discourse. "Few of us," he says, "who have lived for long years far away from this our loved Fatherland, few who remaining at home ourselves claim kindred with some forlorn wanderer in a distant region, can repress the longing for more frequent communion with absent friends." All this and a great deal more of the same kind to be found in his address may be fine writing, but put to the test of experience we know perfectly well is not sound sense, for it does not represent facts. Absent friends are none the less friendly or comfortable for comparatively infrequent communication such as the postal and telegraph tariffs at present compel. There is nothing to be said against frequent communication, however, except that the parties are not given to it, and would not practise it even if the tariffs were reduced to a popular figure. Similarly, the zeal with which Mr. HEATON binds the whole empire with a girdle of cables for its better security in time of war is discounted by a candid survey of the facts. Either the Pacific cable would be incapable of repairs, or it would be liable to be cut, like all the rest of the cables, directly hostilities broke out. The land lines of the Canadian Pacific Railroad, moreover, are flanked along the whole route by a foreign nation who, if not at war with us, could not be counted upon as friendly. That route is no more secure than any other; and to increase the lines of communication merely for the sake of adding to their number will, if we rely upon them, only increase our embarrassments. Lastly, we note that while Mr. HEATON is, as he alleges, devoting his life to the cheapening of postal and telegraphic communication, he seeks to secure the latter by an appeal to the Government which in respect to the former is guilty of unpardonable illiberality. The inter-colonial post is in the hands of the Government, and Mr. HEATON is continually assailing its extravagance and high charges; but it is in the hands of this administration he would place the cable systems of the world, beginning, of course, with Australia;—and ending there, it seems to us, so far as Mr. HEATON'S real aim and object are concerned, whatever specious professions he may urge to the contrary.

THE LAG IN TRANSFORMERS.

BY W. E. AYRTON AND JOHN PERRY.

As the subject of transformers is now exciting much attention, it may be interesting to mention without now going into the details of the experiments that the investigations of the third year students of electrical engineering at the Central Institution made on a closed magnetic circuit transformer have shown:—

1st. That the lag between the currents in the primary and secondary circuits is practically 90° *in excess* of what it would be if there were no self-induction or magnetic lag—that is, the currents in the two coils are nought simultaneously.

2nd. That the magnitude of the ratio of the coefficient of self-induction of the secondary to its resistance is a sufficient and necessary reason for this extra lag of 90°.

THE TELEGRAPH SYSTEM OF THE BRITISH EMPIRE.

A meeting of the Royal Colonial Institute was held on Tuesday evening in the Whitehall Rooms of the Hotel Métropole, when a paper was read by Mr. J. Henniker Heaton, M.P., on "The Postal and Telegraphic Communication of the Empire." Viscount Bury presided, and among the numerous company present were Sir J. Pope Hennessy (Governor of Mauritius), Sir R. N. Fowler, M.P., Sir J. Corry, M.P., Sir J. Anderson, Sir Terence O'Brien (Governor of Heligoland), Sir Graham Berry, Sir J. Puleston, M.P., Mr. Osborne Morgan, Q.C., M.P., Colonel Duncan, M.P., and Mr. W. H. Lawson, M.P.

The CHAIRMAN, in presenting the lecturer to the meeting, said that he needed no introduction from him, as his industry and knowledge of the subject before them were well known to the fellows of the society.

Mr. HENNIKER HEATON, M.P., who was received with applause, in opening his paper, remarked that, having devoted some of the best years of his life to the prosecution of the task of facilitating and extending the development of human intercourse, it was a rare pleasure to him to be able to expound his theories to an assemblage of whose sympathy he was assured beforehand. With regard to the administration of the postal and telegraphic service within the limits of the United Kingdom, he held that certain improvements were feasible and imperative; but, setting these aside, he thought that it could not be disputed that the vast organisation directed by Mr. Raikes had approached very near to the ideal of what such an institution should be. While, however, the poorest classes in the mother country had facilities for communication, the advantages of written and telegraphic intercourse between the 40,000,000 subjects at home and their 270,000,000 fellow subjects in the colonies were virtually denied to all but the wealthy few. The lecturer proceeded to advocate a scheme for an Imperial penny postage.

Turning to the telegraph service, he said there was another and still higher task to be accomplished—the establishment of cheap and abundant facilities for communication by telegraph.

From a space measurable by yards in the capital of the Empire there radiate lines of communication reaching to Vancouver on the one hand and Wellington on the other.

Trade followed the flag, and the telegraph cable followed trade. At this moment practically the whole of the Empire was in communication with the capital.

Digitized by Google

The cables of the world had a total length of 115,000 miles, and cost nearly £40,000,000, the whole of that vast system, with the exception of some 7,000 miles, being in British hands. The majority of the shore stations, too, were on British territory.

The two special points to which he wished to direct attention were the importance of bringing the telegraph into more general use, and the position of the telegraph from a political and strategical point of view.

The telegraph between London, India, South Africa, and the far East, Australia and New Zealand, was a private monopoly vested in the Eastern Telegraph Company, which, like a huge octopus, had fastened its tentacles upon almost every part of the eastern and southern world.

Its own lines ran only to India, but practically it was identical with the Eastern Extension Company, whose lines run to the Australasian Colonies, the Straits Settlements, China and Japan, and with the Eastern and South African Company, with lines running to Zanzibar and the Cape. Sir John Pender was the head centre of this colossal system; he paid a tribute to the marvellous energy and shrewdness by means of which he had created it and fenced it round. It was not only that his companies owned the only line to Australia, but he had made it well nigh impossible for any other line to be laid with advantage to the public.

From the table of charges over the lines referred to it appeared that rates running up to ten, twelve, sixteen, twenty-three, and even twenty-seven shillings per word have to be paid, while the Eastern Company's ordinary shares were now quoted at 15 per cent. premium, the Eastern Extension Company's at 25 per cent. premium, the Indo-European Company's at 25 per cent. premium, and the Great Northern Company's at 40 per cent. premium.

The question came to be, how were we to bring about that reduction of rates which alone can bring the cable into general use, and that immunity from isolation which no single line can afford?

Both objects might be achieved by the one method of constructing an alternative cable *via* Fiji to Vancouver, the Pacific terminus of the new Canadian Pacific Railway, and there connecting with the line through Canada, and across the Atlantic to Valentia.

The Canadian Pacific Railway had been constructed at a cost of £48,000,000, of which about £24,000,000 had been contributed by the Government of Canada in subsidies or without prospect of return. It had brought Vancouver, the uttermost point of Canada, and the chief British naval station in the North Pacific, within a fortnight of Portsmouth. The eastern line of British telegraphs terminated in New Zealand; the western at Vancouver. Connect the two, and at once an electric girdle was put round the world, entirely through British territory. (Applause).

The first section would be from Brisbane or Sydney to North Cape, connecting at the former with the Australian telegraph system, and at the latter with the telegraph system of New Zealand. The length of this section would be 1,300 knots. From North Cape to one of the Fiji Islands, 1,240 knots, would form the second section. The third section would be from Fiji to Fanning Island, 2,270 knots. Then from Fanning Island to one of the Sandwich Islands, probably Hawaii, would be 1,260 knots. From the Sandwich Islands to Barclay Sound or Port San Juan, Vancouver Island, would be 2,730 knots; and from Barclay Sound across Vancouver Island, and the Strait of Georgia, to Vancouver City, the terminus of the Canadian Pacific Railway and telegraph, 100 knots—total, 8,900 geographical miles. The cost was estimated at not less than two millions sterling, and the really practical question is whether the work should be done by a subsidised private company, or should be carried out as a State enterprise by all the Governments interested. An offer had been made to construct this cable for a subsidy of £90,000 a year, but there appeared no doubt that the cheaper course would be for the various Governments to do it themselves. The Governments interested were those of Great Britain, Canada, Hawaii, Fiji, New Zealand, New South Wales, Queensland, Victoria, South Australia, Western Australia, Tasmania, and India, all of which would enjoy the advantages of the alternative route and lower rates of transmission. Now, a private company would want a subsidy of £90,000 a year, and the total capital necessary would be £2,000,000. The Governments would, of course, raise the money at 3 per cent., making an interest charge of £60,000 a year. In reduction of that amount would be the saving made by the Governments in being able to transmit their own messages free; and this amount was estimated at £10,000 a year, so that in reality the burden on the Governments would be only £50,000 a year, or £40,000 less than is asked by the company.

It was pointed out, however—and he quite agreed with it—that the Governments could not properly assist any new corporation to compete with the Eastern companies, who were the pioneers of ocean telegraphy in these parts of the world, and still less could they enter themselves into rivalry with those companies. Faith must be kept. If these monopolies which had grown up were to be destroyed, it must be by just and honourable means.

The logical conclusion was that the Imperial and Colonial Governments should unite to acquire all the existing Imperial telegraphs, and to construct what other lines might be deemed necessary. The existing companies which would be embraced in any such scheme have a total outstanding capital of about 10½ millions. This meant that the cost of the cables must be set down at £300 a knot, or about double the price at which entirely new cables could be laid down now. Moreover, the Eastern companies' cables were most of them not new. The price to be paid for the Eastern Extension lines would be £2,220,000. Then he should propose to construct the new Pacific cable at a cost of £2,000,000, so that a sum of £4,220,000 would suffice to give the independent route *via* Canada, and to compel fair and reasonable concessions from the Eastern Company. The Eastern Extension Company would, of course, have been fully paid out. The interest upon the required capital of £4,200,000 at 3 per cent. would be £126,600; but the purchase of the Eastern Extension Company's business would extinguish subsidies now paid by the Colonies to the amount of £56,700 a year, which would reduce the charge to £69,900. Again, the Hawaiian Government was ready to give £4,000 a year for the establishment of telegraphic communication with America, and this brought the charge down to £65,900. That was the outside total annual cost of the acquisition of complete Governmental control over both the Asiatic and the Canadian telegraphic routes; and he contrasted that sum with the £90,000 annual subsidy demanded by the private company for the construction of the Pacific cable alone. Sir John Pender himself offers to sell these cables at a fairly moderate price (laughter). He maintained that if the Governments acquired the cables they would have from the very beginning a revenue of £300,000, even at the present rates. With reduced rates even Sir John Pender thought that the Imperial telegraphs, taken as a whole, would yield a profit of a million a year. He assumed that the Governments acquired the control of the two routes at the annual charge of £50,000. What follows upon that? No doubt, an immediate reduction of rates. He had expressed the opinion that telegrams could be profitably sent between England and Australia for 1s. a word. The Pacific cable could easily be made to transmit 10 million words a year. That alone would give a revenue of £500,000 a year, sufficient to bear its share of the interest on capital, to pay the working expenses, and to leave a margin of profit. He was only calculating now on the duplicated system of cabling, whereas a new invention has been brought forward by which four messages can be transmitted each way at the same time along a single cable. If they looked away from these islands they saw one slender wire which has to do duty for three, he might say four, continents. They saw foreign Governments lavishing subsidies on packet lines, and carrying foreign merchants' correspondence at half rates to British Colonies and to semi-civilised countries, the trade of which was being insidiously acquired. Worst of all, they knew that every British emigrant was cast off from the mother country as if his patriotism and love of kindred and home had no value. At a moment when envious rivals were looking for a joint in our armour, when dissolving forces were actually at work in the Empire, not an effort was made, not a shilling spent to strengthen and utilise the precious sentiment of brotherhood which nature had planted in the great Anglo-Saxon race (loud applause).

DISCUSSION.

Colonel DUNCAN, M.P., then addressed the meeting, confining his remarks chiefly to the postal service.

Mr. OSBORNE MORGAN, M.P., said he believed that the true solution of the problem was to put the telegraph service, like the postal service, in the hands of the Government; but how to do it was a matter of detail. His hon. friend had converted him from being an opponent into an ardent and sincere supporter of his postal proposition.

Sir R. N. FOWLER, M.P., said he had, in common with his friends who had preceded him, to congratulate his hon. friend upon the very interesting paper to which they had listened with so much pleasure.

Sir JOHN POPE HENNESSY, after referring to the postal question, said: Might he be also allowed to say a single syllable upon that burning question upon which they were soon to hear from Sir James Anderson? He did not at all agree with Mr. Henniker Heaton in some of the remarks he made about the Eastern Telegraph Company, for he could not admit, though it was spoken of as a great monopoly, that it was in any shape or form doing any injury to the Empire; on the contrary, speaking as an official who had been in various Colonies, where he had met with the Eastern Telegraph Company, he was bound to say he knew no company which had done more to bind the Empire together than the Eastern Telegraph Company; and as an illustration of what the Eastern Telegraph Company was endeavouring to do he would mention the case of the Colony with which he had the honour to be connected. Sir Henry Barkly was well aware of the importance of telegraphic communication with Mauritius, because he, too, was a Governor in that Colony, and he knew that the Island of Mauritius was without telegraphic communication. It was called by naval and military men the Key of India, and it was also of great importance for the defence of Australia. And yet they had no telegraphic communication with Mauritius. He received an offer from the Eastern Telegraph Company not many years ago. They undertook to establish telegraphic communication, to

Digitized by Google

run a wire from Africa to Mauritius, and to work that cable for the sum of £20,000 a year. Anyone who knew the responsibility attached to laying down a telegraphic cable and keeping it in repair would understand that that was a most generous offer for the Eastern Telegraph Company to make. He was able to induce the Local Government of Mauritius, the House of Assembly, to vote one-half of that money, £10,000 a year, on the condition that the Imperial Government here would give the other £10,000, which it was thought it should do, having regard to the Imperial interests at stake. He was sorry, however, to say that up to this time he had not been able to induce the Chancellor of the Exchequer in England to give £10,000 a year; but lately he had gone again to the Eastern Telegraph Company, and he found now that they were willing to re-open the question, and he believed for the comparatively small sum that it was proposed to raise in Mauritius they would give the island that cable. He thought the chairman had every reason to congratulate himself upon presiding over a meeting in which a paper of this kind had been read. Many members of Parliament were present under circumstances of which they could understand the difficulty, and he thought it was a subject of congratulation to all members of that Institute that they had been permitted to take a part in the proceedings of the evening.

Sir JAMES ANDERSON thought he might be pardoned if he appeared on this occasion as something of a critic of this paper. So many nice things had been said that a few minutes ago he was frightened; but he had more confidence since the last honourable speaker had said that, after all, the Eastern Telegraph Company, which he represented, was not so bad as the paper made it look. The feeling he had in reading this paper was that it was ornamented with a great deal of inflated language (laughter)—he must be pardoned for saying so—though the honourable members of Parliament who spoke had said things so nice that there seemed to be nothing but niceness about it. The paper opened with the astounding statement that there were 270,000,000 of our Colonial fellow subjects suffering owing to dear postage and dear telegraphic communication.

Mr. HENNIKER HEATON: Nothing of the kind.

Sir JAMES ANDERSON: You say so, pardon me, in the third or fourth line.

Mr. HENNIKER HEATON: No, sir.

Sir JAMES ANDERSON maintained that Mr. Henniker Heaton had stated that 270,000,000 of their Colonial fellow subjects were suffering under the pressure of dear postage and dear telegraphy. In the paper it was also stated that, thanks to the trade with the Colonies (and for this purpose Mr. Henniker Heaton made India a Colony), we were enabled to maintain 500 war ships and 500 clipper steamers for war purposes. Then from that time British India dropped out, and nothing more was heard of it excepting in this way, that for anything done in the way of cheapening telegraphy or postage, the Board of Trade or the Admiralty, or somebody in the mother country, ought to bear the expense. Then, again, it was said that this country and the Colonies were so much indebted to the great steamship companies for having developed Colonial enterprise and Colonial progress that we owed them a debt of gratitude which we could never repay. A few lines further down Mr. Heaton said that he took £100,000 from them. That was one way of paying a debt of gratitude. Mr. Heaton said, again, that he would reduce it more; then that the enormous subsidies must be substantially reduced and taken away altogether. That was his mode of paying the debt of gratitude which could never be repaid. He thought it would be as well to begin at once, and not pay anything. With regard to the Post Office and the Telegraphs Mr. Heaton said that upon them depended the supremacy of their commerce and the stability of the Empire; then there were hundreds of thousands of poor emigrants who could not pay the postage of a letter, but for all that they sent more than £300,000 to their poor relatives in the mother country last year, and in that way he rang the changes; and it was in that way that he meant that Mr. Henniker Heaton had indulged in what he called "too beauteous" language. With regard to Mr. Heaton personally, Sir James remarked that they were old friends and had worked together. Mr. Heaton spoke of the telegraphs as a huge octopus, and of the Eastern Telegraph Company as a terrible and unendurable monopoly. In considering the company as a monopoly, he would ask them to look at the map. All the land in the world east and south of the meridian of Greenwich, excepting America, is there; all the ports of the old world; all the millions of the inhabitants with whom we have been trading all through our history, for British products were sent eastward even in prehistoric times; all the millions of inhabitants with whom we yet hope to establish and develop traffic exist in these great continents, and along that eastern line are the ports of the world where our ships can take shelter in time of war, and our cruisers find supplies. £200,000,000 of our annual foreign trade is there, and 15,000,000 tons of our shipping is employed in that trade, and the British trader had gone there to buy and sell his goods and to bring home the products. It would have been strange if the company had not gone to the places where commerce existed, and where were all the ports of the world. It went without saying that the company laid its cables where the commerce was. The octopus spread out its tentacles to all those ports. Now let them listen to this. The company had no privileges. The company laid that cable all the way to India, Australia, and China, and never got a farthing of subsidy or a bit of encouragement. They laid cables to Spain, to Portugal, to France, Austria, Italy, Greece, Turkey, Russia, Asia Minor, and Egypt, and this so-called monopoly was competing with the Government of every one of these countries at the same tariff. The cables were laid by permission to the ports of these countries, and the company was allowed to have English hands to work them, and the company took its chance of picking up unconsidered trifles which they did not seem to appreciate, and so they paid the enormous sum, as Mr. Henniker Heaton called it, of five per cent., sometimes 5½ per cent. dividend, and that was what had been done by private enterprise. Mr. Heaton said that the company followed the trade and followed the flag. The company followed the flag to Besika Bay, to Gallipoli, to Constantinople, laying a cable within a pistol shot of the Admiral's ship. They went to Port Said and followed Sir Garnet Wolseley to the point of departure for Tel-el-Kebir. That was off the company's "own bat," and no money was paid them for doing it. They laid cables also to Suakim, and the organisation which had effected this result of British enterprise Mr. Heaton spoke of as a gigantic octopus and a private monopoly, and in this respect he thought Mr. Heaton had used undue language and had not been so fair as he ought to have been. With regard to tariff, Mr. Heaton knew very well that the company came down to quarter rates for the press, and not only that, but allowed messages to be "skeletonised," which meant that every word was developed into seven or eight; yet this was the "monopoly" which was held up to censure and scorn by Mr. Heaton. Mr. Heaton thanked him over and over again, and said he thought they were liberal, and that he would be the friend of the company; yet now, for some reason of personal pique, he came forward and read a paper against them as being a gigantic monopoly. With regard to what Mr. Heaton said about the Government control, he (Sir James) claimed to have been the first to put that into his head. At Berlin he proposed the substance of a plan with which Mr. Heaton was very much pleased, and if that plan were adopted the Government might take over the telegraphs, paying 4 per cent. on the present capital, and keeping up the present tariff they would have a quarter of a million to do what they liked with. They could reduce the tariff one half and still make a profit. Private companies could not do that. Sir John Pender had put before the Colonial Conference still another plan. The directors were the trustees of their shareholders, who had a right to demand some interest for their money. They must walk steadily and warily, as they best could. He would take the case of the American cable companies. Four of the cables belonged to Americans and one to the French, and they were not going to give up their cables to the English Government, neither were foreign Governments going to allow the English Government to land, and acquire stations upon their territory, and put English subjects to work the cables. It was all very well for foreign Governments to give such rights to a private company, because they could turn them out, and could always control them, but that was a very different thing to giving the English Government landing rights and stations, and a position upon foreign territory; and if the two ends were to be under different direction and control, with operators of different nationalities, there would be no telegraph at all worthy of the name. Hence he did not think there was any probability, nor did he think there was any great desire, that matters should be otherwise than they were. At the same time, if the Government desired a cheap telegraph, he had shown how they could have it. His own company had not the least desire to keep the monopoly, as it was called. The Government would have to pay the shareholders for it, and not too much either. The company, he contended, had shown as much British pluck and enterprise as their forefathers ever did (applause). He had one word to say about the proposed cables. He did not see any poetry or romance at all, or anything worth talking about, in laying a cable round the globe from east to west any more than from north to south. He did not see the use of it. There was nobody there to telegraph. There was talk of taking a cable all the way from Australia to the Mauritius, across the route of the trade winds to the Cape. There was not even a sandbank on which to catch fish; there was not a port to which a cruiser or a cable ship could go to replenish their supply of coal, which they were certain to require to do. There were no ships going there; there was no trade, and nobody wanted to go there. Take the cable from Canada down to Fiji and New Caledonia, which was a French convict settlement. Well, what was there? Mr. Heaton, in his paper, dropped India and China, he dropped the Cape, and he dropped everything but Australia, where the whole of his mind was centred, and naturally so, he should suppose (laughter). He wanted a cable from Australia, where there were four millions of people, to go round the Cape or across the Pacific. He (Sir James) did not believe in it a bit, and he hoped that no one with whom he had influence would ever put a penny of money into it, but leave it to those gentlemen who did not know any better. They did not know what was involved in laying long cables in vast oceans. They would all want repairs in time, and they must have large ships with great coal endurance to go out for that purpose, because there was no place where their coal supplies could be replenished. These cables were, of course, to compete for all the trade, and to take it away from this poor company. Another word about the "monopoly." The competing companies (Indo-European and Eastern), neither of whom could at one time make a living, naturally combined and formed a working agreement, as anyone would combine if they found it to their advantage, in a free country. Well, that was the head and front of their offence, and to have held the companies up for doing so was something that Mr. Henniker-Heaton should regret. At any rate, he did not think it was fair. Does he believe that the Governments of Russia, of Germany, of Austria, of France, &c., would agree to the Government of Great Britain having all the cables in their own hands? Of course they would not. They would not let them take the Indo-European line or the Russian overland wire. Again and again he was told when he was in St. Petersburg some years ago by the Russian Postmaster-General that, no matter whether it paid or not, no matter what they lost by it, they would maintain that line for political purposes. He had just one other word to say about war. The idea that the submarine cables could or should be relied upon in time of war was nonsense. He had taken every opportunity of saying so. The Colony, or the merchant, or Government, or admiral, or commander-in-chief who did not arrange his plans so as to know what he would do when the cables were cut on war breaking out, was not fit to be at the head of the concern. All that they could do in time of war was to take the best care they could,

Digitized by Google

when the cables were cut, to repair them as soon as possible. These "monopoly" companies had at present 2,000 miles of cables in tanks in nine parts of the world. They had eight cable steamers ready at this moment to effect repairs, and if they saw a glimpse of war clouds they could double both ships and cables. And that was the policy every one would have to adopt. The commander-in-chief of the army, the admiral of the navy, would have to see his plans arranged so as to hold his own somehow or another, as he best could, till he could get into communication with headquarters if he required reinforcement. There was no other way of dealing with the question of cables in time of war (applause).

The CHAIRMAN said it was not his duty to decide which among the various opinions which had been expressed was the right opinion, but to sum up, in a very few words, the result of the debate, and to conclude by proposing a hearty vote of thanks to the lecturer. It seemed to him that both sides were a little carried away. Mr. Henniker Heaton was, fortunately for the world, an enthusiast. It was well that there should be men who, pushing all obstacles aside, should fix their eyes on some great idea to be realised. He thought the suggestion of Mr. Henniker Heaton, that the Government should take over the cables, was contradictory. He was evidently not satisfied with the Government. He thought that where a Government made a profit upon one part of their business, that profit ought to be expended in diminishing the expense of another part. He did not seem to think about the Government doing their duty well. As to the Telegraph Department, he was afraid that the feelings of his dear old friend, Sir James Anderson, had been very much ruffled by his company being referred to as an octopus. He thought it was greatly to the credit of that company, under Sir James's auspices, that it should have spread its feelers all over the world. Mr. Henniker Heaton thought that the work could be done by the Government with satisfaction to the telegraph companies and with less burden on the community. Well, he thought there was something in that argument. The Chairman proceeded to give an instance that occurred in connection with an important company, of which he was chairman, in which he wished for a return from the Cape of Good Hope of some commercial transaction in which the company had been engaged. He directed the secretary to ask by letter for a return by telegraph of certain sums which had been paid in that country. A cipher telegram came back without the slightest delay, but the result was not particularly intelligible, or exactly what they wanted. The company was very anxious to have full information, and he directed the secretary to telegraph back and have the telegram repeated in plain figures. Then it came to be a question of cost, and he decided not to go to so high a figure as from £15 to £20. The cable was probably vacant for several hours during the day on which that event happened, and the Company might have repeated the message, in his opinion, for about 5s. a word, or much less, perhaps, without losing anything. As it was they did not get his £30, but if it had been a question of £10 instead of £30, they would have got it. That, he took it, was a specimen of transactions which probably often occurred, and which would result to the advantage of the Company if the tariff had been smaller. Mr. Henniker Heaton did not blame the companies because they made the best living they could for themselves. He only hoped that it would become patent to the world that lower rates, whether by post or by telegraph, would be an advantage. It was not a question of finding fault at all one way or the other, but as Sir John Pope Hennessy said, it was a grave question of finance, and finance only. It would eventually be seen that just as the penny post enormously increased the amount of correspondence, and therefore enormously increased the revenue of the Post Office, so lower telegraph rates and lower postal rates would eventually redound to the advantage of the sender and carrier. He believed that to be, in one word, the point at issue. He concluded by proposing a vote of thanks to Mr. Henniker Heaton for his lecture, which was carried by acclamation.

Mr. HENNIKER HEATON, in reply, said he thought it was a matter for congratulation that they should have had four gentlemen speaking who might be regarded as representatives of the four great objects of attack. With regard to Mr. Pearson Hill, that gentleman asked him to do his best to get the Australian Colonies to join the postal union. The postal union was the greatest humbug they had. From England to British India the postal charge was 5d., whereas it was only 2½d. from France. The idea of joining a postal union in which such an anomaly as that existed! When he asked the Postmaster-General whether he would reduce the rate to 2½d., he said, "No, I cannot reduce it under 5d." That was what would be gained by the postal union. He hoped that within the next 48 hours a reduction of 50 per cent. in the rate to Australia, namely, from 6d. to 3d., would be announced. It was only a little time ago that he heard Mr. Pearson Hill read a paper before the London Chamber of Commerce on the reduction of postage to 2½d. It appeared, therefore, that Mr. Hill was in favour of a reduction, though he did not go so far as he did. He did not think that a reduction to 2½d. would have been obtained if a reduction to 1d. had not been asked for. Sir James Anderson rather gave them to understand that not a farthing of subsidy was received by the Eastern Telegraph Company from anybody, and that they had no privileges at all.

Sir JAMES ANDERSON: We laid our cables to India and China, and up to that time we got nothing. Afterwards Australia wanted cables, and we got a subsidy.

Mr. HENNIKER HEATON stated that it was a fact that Sir James Anderson received a subsidy of £32,000 a year from the Australian Government. That was a terrible thing for any rival company to deal with. What could they do under any circumstances but buy this octopus out (laughter)? The Eastern Extension Company, of which Sir John Pender was chairman, got £60,000 a year for the South African cable. He opposed it in the House of Commons, but he was not quite strong enough for these gentlemen. Mr. Henniker Heaton concluded by proposing a vote of thanks to the chairman.

THE ELECTRIC LIGHT IN ROME.

The Electric light has lately made rapid progress in Rome. We have already chronicled the establishment of a central station by the gas company, from which distribution is effected by means of transformers on the Zipernowski system. The Municipal Council has recently authorised the erection of nine arc lamps upon the Piazza della Quirinal. These lamps take a current of 16 amperes, and are placed upon posts 22ft. high. The lamps are of 1,000 candle-power nominal, and are enclosed in opaline globes. The posts are of very ornamental design, and the effect of the whole is very pleasing. The current is supplied by transformers, which are placed at one of the corners of the Municipal Buildings in a small chamber built into the wall. A special underground conductor has been laid down as far as the corner of the Via Nationale. This underground line is working extremely well at present. The cables were supplied by Siemens, of Berlin, and in point of economy compare favourably with the Berthoud-Borel type, which is chiefly used by the Gas Company. The Quirinal Theatre possesses an installation of 200 incandescent lamps. The lamps upon the stage are regulated by means of a set of impedance coils, a feature to which the transformer system readily lends itself. The Theatre Metastasio is lit in the same manner, but in this case arc lights are used for the stage lighting. Several powerful projectors are employed, which are regulated by hand. In both cases the lighting is of a highly successful character. The extensive retail establishment of Bocconi Frates has also been lit throughout. It comprises 86 arc lamps of 2,000 candles, and 200 incandescents of 16 candle-power. The incandescent lamps are supplied by an Edison dynamo driven by an Otto gas engine of 12-horse power nominal. The arc lamps are divided into ten separate circuits, each supplied from a separate transformer placed in the cellar of the establishment. The current is charged for per lamp-hour, and not by meter. Another installation worthy of mention is to be found upon the premises of Finzi and Beanchelli. Five arc lamps of 500 candle-power are hung outside the windows of the shop, and the interior is lit by nine lamps of the same size. These lamps take a current of eight amperes. The total motive power available in the central station amounts at present to 1,500 horse-power. The whole of the installations referred to have been carried out within the last few months.

MAGNESIUM AS A POSITIVE ELEMENT.

Owing to the high price of magnesium it has not hitherto been worth while to consider its use in the primary battery as a substitute for zinc. The metal has, however, lately been falling in value, owing to the introduction of the electrolytic process in its manufacture, and is now worth about 9s. per pound. Although this price is still prohibitive for ordinary purposes, yet M. Hein, in view of the possibilities of a further reduction, has made a careful study of the E.M.F.'s obtainable with magnesium cells, and has published the results in a recent number of the *Elektrotechnische Zeitschrift*. From this paper we compile the following tables :—

DANIELL CELL TYPE.

Positive element.	Solution.	Negative element.	Solution.	E.M.F. in volts.
Magnesium	Dilute sulphuric acid	Zinc	Dilute sulphuric acid	0·876
Magnesium	Dilute sulphuric acid	Copper	Sulphate of copper	2·03
Magnesium	Sulphate of magnesium	Copper	Sulphate of copper	1·93

The substitution of magnesium for zinc in an ordinary Daniell cell therefore increases the E.M.F. by about 0·85 volt.

BUNSEN CELL TYPE.

Magnesium	Dilute sulphuric acid	Carbon	Dilute nitric acid	2·888
Magnesium	Sulphate of magnesium	Carbon	Dilute nitric acid	2·863
Magnesium	Chloride of magnesium	Carbon	Dilute nitric acid	2·910

The substitution of magnesium for zinc in a Bunsen cell therefore increases the E.M.F. by about 0·89 volt. Using a specially hard "electric light carbon," an E.M.F. as high as 3·023 volts was obtained.

BICHROMATE CELL TYPE.

Magnesium	Bichromate solution	Carbon	Bichromate solution	2·952
Magnesium	Dilute sulphuric acid	Carbon	Bichromate solution	2·980
Magnesium	Sulphate of magnesium	Carbon	Bichromate solution	2·901
Magnesium	Chloride of magnesium	Carbon	Bichromate solution	2·970
Magnesium	Chloride of magnesium	Carbon	Specially concentrated solution.	3·046

The substitution of magnesium for zinc in bichromate cells increases the E.M.F. by nearly 1 volt.

Digitized by Google

LECLANCHÉ CELL TYPE.

Magnesium	Chloride of ammonia	Carbon & dioxide of manganese.	Chloride of ammonia	2·219
Magnesium	Chloride of magnesium	Carbon & dioxide of manganese.	Chloride of ammonia	2·334

The substitution of magnesium for zinc in Leclanché cells therefore increases the E.M.F. by about 0·63 volt.

Unfortunately, it appears that it is difficult to prevent a considerable amount of local action in these cells, and it should, moreover, be noted that the magnesium salts in solution have a specific resistance from 30 to 50 per cent. higher than that of the corresponding zinc salts. M. Hein is, however, of opinion that when a small current of high E.M.F. is required the Leclanché type will prove useful, and even, in some cases, economical. For instance, for medical purposes he considers this cell to be decidedly preferable to the bichromate type, in which, in order to obtain a constant E.M.F., the frequent renewal of the solution is necessary. The Leclanché type has, of course, the further advantage that it does not require the use of acid solutions.

CENTRAL STATION LIGHTING.

INDEPENDENT ENGINES IN INDEPENDENT STATIONS.*

BY WILLIAM LEE CHURCH.

The service of electric lighting differs from other forms of manufacture in requiring more horse-power per square foot of floor space; in requiring higher speeds; in demanding the power in larger units; in compelling a closer and more uniform regulation; and in requiring more rapid and constant extensions. It will be observed that these peculiarities require individual and special treatment in the generation and distribution of power, and engineering practice as determined in other means of manufacture may be sadly at fault when applied to electric lighting.

It has become an axiom among experienced station managers that the money is made or lost between the shovel and the belt; in other words, other things being equal, the dividend-earning capacity of a station is determined by its steam plant, to which the electric apparatus is in the nature of an accessory.

Incandescent lighting has not until recently made a brilliant record as an investment, and much of the disappointment is directly traceable to the culpable ignorance of the principles of steam engineering which has been displayed. A man who will not venture to cut himself a $2.00 vest will not hesitate to exercise his amateur talents upon a steam plant, upon the economical and reliable performance of which depends an investment of one hundred thousand dollars and the public service of a city. A long and critical experience in this branch of industry has grounded us in the conviction that no incandescent station can hope to be financially successful, under the ordinary conditions of competition, unless based on independent dynamos belted direct from independent engines. Throughout this paper, therefore, we desire to keep constantly in view the opposite systems—namely, a station containing a given number of dynamos of two or three different capacities, each belted direct from high-speed engines of corresponding rating, and, on the other hand, the same station with the dynamos driven from one or two slow-speed engines transmitting their power through one hundred feet of shafting, more or less, encumbered with clutch pulleys. Having these pictures well in mind, we inquire:

What are the essential requirements of a first-class steam plant in an incandescent electric light station? Taking them up in the order of their importance, we unhesitatingly say first, and always foremost, *absolute reliability for continuous running.*

The electric light company contracts to supply the demand of a diverse and exacting public, and that public expects to find its light on tap at every moment of every hour of every day in the year. Failure of service in ever so small a degree is palliated by no excuse. Complete reliability is the condition of popularity, confidence and patronage, without which all the other economies and excellencies go for nothing.

Again, electric lighting perhaps more than any other industry has its earnings directly affected by the shutting down of its power, since it sustains a direct financial loss for lights out, aside from custom and reputation, not easily regained. Subdivided power reduces this risk to a minimum, and, properly directed and applied, obviates it altogether. In a station using, say, 2,000 horse-power, say in the shape of two large engines, loss in lamps in one night by the shutting-down of one of these engines is equal to one-half the cost of an independent engine on the subdivided plan; in other words, as tersely expressed by a manager of experience, a company might better, for peace of mind, reputation, and cash balance on the books, throw a 60 horse-power engine into the scrap pile than to shut down the station one hour. The service of electric lighting is similar to the editing of a daily paper, in that lost time can never be regained. Most industries can make up lost time by working overtime, and pushing their business in various ways, but in electric lighting—

"The mill will never grind with the water that has passed."

Passing from argument to instance, we cite the recent experience of one of the largest stations in the country, operating in the neighbourhood of 20,000 lights. This station, as originally planned, was driven from a pair of Corliss engines, each having a cylinder 28in. in diameter by 48in. stroke, and belting to a countershaft 4½in. in diameter by about 50ft. in length. From this countershaft are driven five dynamos, having an aggregate capacity of six thousand 16 candle-power lamps. Clutch pulleys 8ft. in diameter, which are the means of disconnecting the dynamos when not in use, with similar clutch pulleys for exciters. The remaining dynamos in the station are each of 2,500 lights capacity, and each driven by a 200 horse-power independent engine, belted direct. Recently, in the middle of the heavy run of the evening, one of the clutch pulleys broke in some of its parts, necessitating the immediate shutting down of the 6,000 lights, besides doing considerable damage and involving danger to the *employés*. The extinguishing of such a large number of lights at the important hour of the run was a blow at electric lighting of the severest nature, and working serious inconvenience to public gatherings. It happened that one of the independent engines, with its dynamo, was immediately available, and was started within two or three minutes, so as to take up a portion of the load of the large engine. In this same station, at a subsequent time, a key became loose on the valve gear of the engine, necessitating another stop for several minutes. On still a third occasion the crankpin became uncomfortably hot, and was carried through the run only at a great risk and labour. This illustration is used as one among many of the almost evident fact that no electric light station can afford to hang its whole business upon any one source of motive power, particularly when that motive power is distributed through the complex mechanism of countershafting, clutch pulleys, &c., involving a risk of hot bearings, broken pulleys, defective frictions, and what not, any one of which may shut down the whole station. Had these dynamos been each belted from an independent engine, the accidents above enumerated could not have occurred in the nature of the case. We do not assume to say but that accidents of some nature are due in any piece of mechanism; but the division of power and generating capacity into comparatively small units, each independent of all the others, affords a practical means of distributing the danger, so that it is essentially *nil* in its effects; that is to say, had a stoppage of any one independent engine in a similar instance occurred from any cause, the other engines, with their dynamos, would easily have distributed the load for a short time, without any disturbance or danger whatever, and the service would have been uninterrupted while the repairs were being made or the difficulties remedied.

It has been incidentally remarked by a gentleman familiar with the practical operation of a station, that independent engines afford a safeguard against danger from short circuits, inasmuch as currents of the short circuits will overload an independent engine and slow it down, thus giving warning of the danger. If the dynamo is driven from a single large engine,

* Paper read before the National Electric Light Association, at Pittsburgh.

Digitized by Google

motive power will not respond to the short circuit until the short circuit becomes equal to the full capacity of all the connected dynamos plus the range of power in the engine. Practically, therefore, an engine of this type will not feel the short circuit, but will pull it through until something burns away.

The merit of the steam plant which is most obvious, and which appeals most strongly to the electric light company, is *economy of fuel*.

The advocates of large slow-speed engines rely upon the supposed superior fuel of this type as the sole effect to its obvious disadvantages. All managers unhesitatingly admit the superiority of transmitting the power directly and without loss from the engines to the dynamos, and more or less readily concede that in its performance the high-speed engine will also equal the running qualities and durability of the slow-speed engine. If with this, say they, we could get the steam efficiency of the Corliss engine, no man would hesitate to decide in the favour of the convenient, compact, and independent small engine. We take the question at once by the beard, and desire to state that, of two incandescent stations operating under ordinary circumstances, and otherwise equal, except only in their power and transmission, that one which has independent direct belted engines will show on its monthly report sheet, not a small amount, but from one-third to one-half less coal per lamp hour than a station driven from a single engine through counter-shafting, both types of engine being non-condensing. We go yet further, and state that independent non-condensing engines, under many conditions, will about equal in monthly coal account an equivalent slow-speed condensing engine. This is a fact so incontrovertible when actually and candidly investigated that we do not propose here to demonstrate, but merely to illustrate it.

We now submit the prompt inquiry, "Will not a high-speed engine use more coal per horse-power per hour than a Corliss engine?" Yes. "How much more?" Size for size, and load for load, not over 10 to 12 per cent. Score 10 per cent. against the high-speed engine, and again ask, "Will not several small engines use more steam than one equivalent large engine, even of the same type?" Yes. "How much more?" Load for load possibly another 10 per cent. Score 20 per cent. against the high-speed engine, and again ask how an admitted loss of one pound of coal in every five can be reconciled with the statement of a monthly saving of 30 to 50 per cent. in favour of independent engines? Answer, simply because we have to deal with conditions as they exist in fact, and not as we assume them to exist.

The reasons why independent engines can overcome their moderate lack of initial economy and pass a large percentage of actual economy to their credit are mainly two. First, the use of a counter-shaft implies power to run it. Indicator diagrams show that the real load of such a plant varies from 12 to 20 per cent. of the gross horse-power under full load when in ordinary good condition, and not infrequently rises to 30 per cent. and over, with badly lined shaftings and badly drawing pulleys. Moreover, it must be borne in mind that the dead loss is nearly a constant quantity, and if it amounts to 20 per cent. of the full load it will under partial load equal, and even exceed, the net power transmitted to the dynamos. It may easily happen, and doubtless does happen every night in every station thus far, that from midnight to morning two or three horse-powers are expended in the cylinder for each effective horse-power recovered at the dynamo pulley.

Thus, by one stroke and by a single item, is the conceded advantage of the larger engine reckoned in coal per horse-power practically swept away, and large and small engines left standing on an equal footing, prepared to submit to the still more searching question, "What is the cost from hour to hour of the power actually expended in meeting the fluctuation of the load?"

To consider for a moment some abstract facts in steam engineering, we must note that the steam engine develops its maximum economy (*i.e.*, minimum consumption) only over a limited range of its power. Under normal conditions of pressure, say eighty to a hundred pounds in the boiler, this minimum consumption is found only between the points of $\frac{1}{8}$ and $\frac{1}{4}$ cut-off, say from A to B (Fig. 1), at which latter point all engines are now treated. At its rated power, therefore, the single large engine of the Corliss type will consume as little as 26 to 28 pounds of water (steam) actually fed to the boilers per indicated horse-power per hour; and if the economy were not affected by the load, we could represent the rate of consumption by the straight line C D. If overloaded, however, the rate of water consumption rises, as shown on the right-hand portion of the diagram, in which the horizontal distances represent the actual points of water consumption; the curve, therefore, being a curve of efficiency at varying loads, it will now be particularly noted that, whereas the load rises for an overload, it also rises for an underload, and very much more rapidly. This is well understood to be partly from excessive condensation due to over-expansion, and partly from the greater ranges of leakage under short cut-offs. Considering Fig. 1 to represent the actual performance of a 400 horse-power engine at varying points of cut-off, it will be seen that the engine can be at its best only over a limited range, from A to C, or say from 325 to 450 horse-power. An overload is, of course, mechanically injurious which limits the possibilities in that direction. As the load falls off below one-fifth cut-off, the steam rate increases at an enormous ratio, so that at 200 horse-power the engine is using 50 per cent. more than its normal rate; *i.e.*, at 200 horse-power it is actually using the gross amount of steam which would give 300 horse-power if used in a 300 horse-power engine. At 100 horse-power waste is fully 100 per cent., and the steam used should develop, not 100 horse-power, but 200 horse-power if used in a 200 horse-power engine. It must be borne in mind that the diagram is plotted from observed facts, and is not a diagram of theoretical deductions.

It now remains to determine if the conditions actually obtained in electric lighting stations are such as will enable a single large engine to develop its normal economy; and, if not, then are they such as will enable the smaller independent engine with a lesser initial economy to reach a better gross result under the inevitable conditions as they are found to exist.

The typical daily chart of amperes delivered from an incandescent station of, say, 4,500 lights, is shown in Fig. 2, of course with variations in different stations, but always of the same general character. The chart is assumed to cover a winter night's run, commencing at 4 p.m., and shutting down at 8 a.m. The heavy, irregular line, A B, represents the fluctuation of the actual load, such as would be determined by indicating a series of independent engines; and the area enclosed between it in the base line, M N, may be denominated by the net power required. The fine, irregular line, C D, encloses the gross load when driven by a single large engine, being equivalent to the net load plus the friction of the shafting and pulleys required in transmission. The irregular band lying between A B and C D, therefore, represents the dead load, which would be a dead loss, due to the friction of the shafting. But, as above shown, this is the full measure of the loss. We have already seen in Fig. 1 that an excessive underload requires a relative amount of steam which would be adequate to produce a much greater power if applied in an engine worked at its point of maximum efficiency. Combining the two diagrams, therefore, we would find a third dotted line, E F, which would clearly represent the actual steam consumption required to secure the net work A B. The irregular band, therefore, between A B and E F, represents the total loss expressed in coal; in other words, the entire area E F M N represents the lamps which should be got for the steam expended, whereas A B M N represents the lamps actually got for the steam expended. The loss involved is practically 50 per cent. of the total fuel in the whole night's run, which corresponds to observed results in stations whose fluctuations of load are about as indicated. Of course, there are stations in which the net load averages more uniform than that shown, and a better proportionate result would therefore be expected from the single large engine with countershafting. We believe it is safe to say, however, that there is no incandescent station which will get a load so constant as to secure the economy from a single engine equal to that which can be realised from subdivided power.

Digitized by Google

We now contrast the performance of independent engines in the same station. The lower narrow band between the lines M N and *a a* represents the smallest dynamo, equal to a load of 650 lights. The remaining three bands between *a a*, *b b*, and *c c* represent the other dynamos, or successive loads of 1,300 lights each. At starting time, therefore, a 60 horse-power engine with its 650-light dynamo is started, and run con-

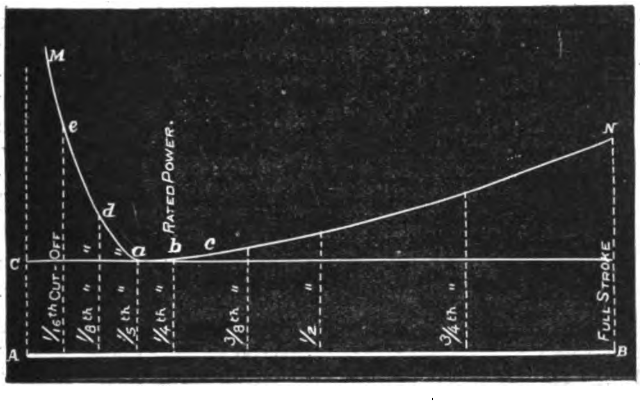

FIG. 1.—W. L. Church's diagram, giving efficiency curve of a 40 horse-power variable cut-off engine.

EXPLANATION—LIMITS OF HIGH EFFICIENCY.—Between *a* and *c*, or 325 to 450 horse-power. All other loads above or below these points show rapid fall in efficiency, *i.e.*, rapid rise in rate of steam consumption. The point *e* in the curve shows rate of steam consumption for 100 horse-power, while *d* represents that for 200 horse-power on the 400 horse-power engine. The diagram being plotted from observed facts, shows conclusively that such an engine can be run with high efficiency only between loads *a* and *c*, a moderate range below and above the rated power.

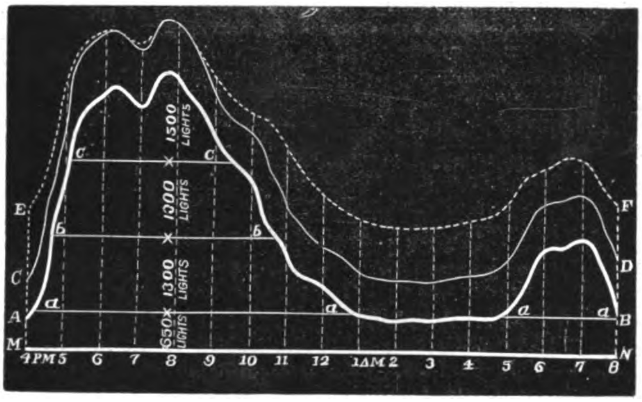

FIG. 2.—Church's diagram, based on actual performance in two stations, one operated by single large engine, and the other by independent engines.

EXPLANATION—WITH SINGLE LARGE ENGINE.—*A B* variable load between 4 p.m. and 8 a.m. *C D* gross load, including friction of transmission. *E F* steam consumption required for network *A B*. Area. *A B E F* = total loss expressed in coal = about 50 per cent. of total fuel used in the night's run.

WITH INDEPENDENT ENGINES.—One 60 horse power for 650 lights, two 125 horse-power for 1,300 lights each, and one for 1,500 lights.

The 60 horse-power engine is run at maximum efficiency throughout the night, indicated by *a a a a*. As load rises one 125 horse-power engine is started at 4:10 p.m., and driven at maximum efficiency till 11:45, and continued at lower efficiency till 12:45 (line *b b*).

Another 125 horse-power engine starts at 4:40 p.m. and runs at maximum efficiency till 9:30, and stops at 10:45, its last hour only showing falling efficiency (line *c c*). The fourth engine runs only from 5 to 9:30 p.m. at nearly maximum efficiency.

The contrast between the two methods of installation is most striking, as thus graphically represented. Each engine runs at its best range of efficiency, and only so long as its load is called for, then stops, and with it all consumption of steam, leakage, radiation, and wear and tear, and plenty of time is left for inspection and repairs if required.

tinuously until shutting down in the morning. It will be noted that, while running, the load on this engine is practically constant and at the point of maximum efficiency. In ten minutes after starting, the load rapidly increasing, it becomes necessary to start the second 125 horse-power engine with its 1,300-light dynamo, which engine again runs on its full and most [illegible]icient load, as indicated between the lines *a a*, *b b*. This engine is stopped at 12:45, and is therefore running to a disadvantage only for the last hour. At 4:40 the increase of light calls for the third engine with its dynamo, which in turn runs until 10:45, and is then stopped. The fourth engine and dynamo will start at 5 p.m., and run until 9:30. The point to be clearly understood as vital to the whole economic question is, that each engine while running is loaded to its best efficiency, runs only so long as its load is called for, then stops altogether, and with it all consumption of steam, leakage, radiation, wear and tear, and loss of every nature. Ample time is given to inspect the engines and dynamo if necessary, and the system as a whole develops the last possibilities of commercial efficiency.

The above diagram practically represents the performance of two stations which we once had the privilege of comparing. Both were practically the same size, and both were constructed on the same electrical basis. We were by courtesy put in possession of the monthly reports from both these stations, which showed a ratio between the pounds of coal per ampere per hour of 70 to 126 in favour of the station driven by independent engines. A station whose motive power is one or two large engines, therefore, finds itself in a position of earning money between starting time and ten o'clock, and spending it again between ten o'clock and the morinng.

We have thus endeavoured to make it clear in the above illustrations that the rated economy of the two types of engines is but a small part of the consideration, and cuts practically no figure whatever in actual practice under the conditions imposed by the nature of incandescent service.

If any one is now thinking to inquire, why not use a number of small Corliss engines in place of high-speed engines, if it is admitted that the Corliss type is more economical of the two, we would answer briefly, first, small Corliss engines are not as economical as small single-valve engines, the percentage of leakage due to the four valves and slower speed being much greater; second, small engines of the Corliss type run necessarily at so slow a speed as to preclude the possibility of direct belting, and to involve full lines of counter-shafting with their attendant cost and waste of power; third, the first cost of small slow-speed engines is very greatly in excess of that of high-speed engines of the same power. We think no one has ever seriously considered, however, the adoption of small independent slow-speed engines.

Next in importance to reliability and economy is uniformity, delicacy, and continuity of regulation.

There is much misapprehension regarding the matter of regulation in engines used for electric lighting. Let us, therefore, ask, What is good regulation? Good regulation implies, as a matter of course, reasonably small variation of speed, reckoned in R. P. M., between the engine fully loaded and the engine running light. Claims are made that such and such engines regulate to 2 per cent., 1 per cent., and even to one-half of one per cent., under variations of load. Now, it should be clearly understood, once for all, that any decent automatic engine controlled by the shaft governor can be so adjusted, not merely to 2 per cent. or 1 per cent., but to actually pass the point of exact regulation, and run faster under load than when light. So far as regulation in terms of R. P. H. is concerned, 1 per cent. or 2 per cent. regulation is sufficiently close for all ordinary purposes.

Second. The most important consideration in the regulation of engines in incandescent stations is not their variation from minute to minute, but from stroke to stroke. An engine may make 300 turns per minute, counted for each successive minute of the hour, and yet may at any given instant be running sensibly above or below this speed, in the effort to meet a momentary fluctuation of load. We say every engine may do this, and we have observed that most engines do this frequently; the difficulty being, not a matter of the construction of the governor, but purely a question of lubrication. A perfect governor is one which will maintain the speed, not at an average of 300 R. P. M., but at the rate of 300 R. P. M. for each and every stroke. Any properly constructed governor will retain the average of regulation to which it is set, but it can only secure instantaneous

Digitized by Google

regulation when friction is practically eliminated. It has been our experience that nothing but a complete bathing of the governor in oil will practically accomplish this purpose and maintain its perfection throughout a long run.

Incandescent lamps require a regulation more delicate, perhaps, than any other industry. Any departure in regulation from stroke to stroke gives a variation of electromotive force, which is speedily destructive to the life of the lamp—the item which, next to fuel economy, is the heaviest taxation. The injury is done during the period of acceleration immediately following the change of load, which period is the time between the change of load and the movement of the governor; and this in turn is proportional to the friction. It is obvious that, if friction were annihilated, the acceleration would be also *nil*, and the speed, and consequently the electromotive force, would never vary.

Third. Under the extremely long runs now imposed by electric lighting service, continuity of good regulation is essential; that is to say, a governor which will regulate when well oiled, will fail to regulate when its pins and bearings, being inaccessible under motion, have become dry during a long run.

As to the nicety of regulation obtainable from a slow-speed engine, there is no comparison possible. We have already shown that it is not permissible for an electric light engine to vary its speed, even from stroke to stroke. A slow-speed engine not only may do this, but actually does vary its speed within the limits of a single stroke. All observers know that it is frequently quite possible to count the revolutions of a slow-speed engine, particularly when heavily loaded, by the pulsations in the lamps at a distance from the station. A slow-speed engine, unless excessive in its fly-wheel capacity, will imperceptibly slacken in passing its centres; and this variation, not visible on the engine, becomes a sensible and dangerous variation when multiplied to the speed of the dynamo. The fluctuation of the needle of two voltameters, respectively registering from a high-speed and slow-speed engine, will give abundant evidence on this point.

Flexibility.—The characteristic of flexibility in electric light stations is one which is frequently overlooked until experience demonstrates its desirability. To secure the best possibilities in this direction, it is necessary to use dynamos of two or three different sizes—say of 650, 1,300, and 2,500 lights capacity—each being driven direct from an independent. The plant being thus divided into independent units of different sizes in any variation of demand, either in the total load or in the load required for different circuits, can be conveniently met. Owing to local causes, the load of a station is not necessarily the same from day to day. It is obvious that a plant in which all the dynamos are hung upon one, or at most two, engines, is essentially rigid in its control of circumstances, whereas a station planned as above indicated is to the last degree flexible in meeting any variation of load, to whatever degree it may occur. All this has a direct bearing both on economy of fuel and incidentals of operation.

We would wish to imply that the smallest unit in every station should necessarily be the smallest dynamo—say, 650 lights. It is probable that the smallest unit is determined by the minimum load existing at any considerable time during the day. This minimum load in the majority of medium-sized stations will represent about one-eighth to one-sixth the generating capacity of the station—that is to say, a station of 4,000 lights capacity should have one dynamo at least as small as 650 lights. Beyond this, it is perhaps advisable that the units be uniform for the sake of interchangeability of parts. The whole question of units of generation must be considered, not in the light of any one rule, but under all the circumstances of each particular case.

Maintenance of Plant.—The maintenance account of a plant often defeats dividends in the use of counter-shafting, bearings, pulleys, clutch pulleys, belts, &c. No practical operator need be told of the repair account and general annoyance from the use of clutch pulleys. There are incidental exceptions, but we refer to the general rule. Each bearing of the counter-shafting will consume oil to the value of at least $5 per annum, and any considerable amount of shafting involves the pay of an extra oiler to properly care for it. Regarding the two types of engines under discussion, it is undoubtedly true that the maintenance of the high-speed engine will be fully as low as of an equal horse-power in slow speeds, as to its actual expense, without taking into account the time lost in repairs. Nearly all high-speed engines are made to gauge with more or less reference to interchangeability of parts. Repairs in consequence are furnished at a minimum of cost, and the parts being light and readily handled, the engine can be stripped and overhauled and connected up without the employment of an extra force of men, or the necessity of heavy handling. In referring to high-speed engines, we of course only speak of those which are carefully and understandingly designed for the work put upon them; that is, we wish to draw a sharp distinction between high-speed engines and engines speeded high.

Space Occupied.—This is one of the minor considerations which in certain locations becomes of considerable importance. Not infrequently electric light stations are located near the business portion of a city, where real estate is valuable, and taxes correspondingly high, and space counts heavily in the capitalised investment.

Again, a large building obviously increases the investment, particularly when we know that a building to carry heavy lines of shafting at high speeds must be of unusually massive construction. It needs no illustration to show that independent engines, by doing away with the space occupied by counter-shafting and belts under the least distance between centres which can be justified, require materially less space per horse-power than any form of non-subdivided power. This is particularly the case where the dynamos are placed on the second floor over the engine room.

Moreover, the cramped space in which the single engine must develop and distribute its power is against its satisfactory performance. The fact is generally overlooked, in drawing comparisons, that a single large engine in an ordinary manufacturing establishment, such as a cotton mill, has in the nature of the case a wide space in which to transmit its power from the slow motions of the engine up to the high speed of the spindles. This means that ample space is given to bring the speed, by gradual accelerations, through easy moving shafting of substantial nature, up to a moderately high intermediate speed, and then distribute it to the spindles in small quantities, by means of simple and light fast-running devices. In the dynamo room, on the contrary, the space is cramped to the last degree and the slow-running engine must, in short range, multiply its power to high velocities, and transmit its speed in large units to the dynamos. The whole system of transmission becomes rigid and ineffective, and the loss consequent upon friction, and risk to *employés*, and the magnitude of disaster when any occurs, are such as in themselves to overbalance all the ecomomy which the most enthusiastic advocates of slow-speed engines attribute to them.

Extension of Plant.—An electric light station, unlike most other industries, is usually of very rapid and persistent growth, to an extent which is not generally foreseen in the original calculations. The use of independent engines lends itself readily to indefinite extension. The power and dynamos both being divided into like units, each independent of all the others, extension becomes merely a question of more units, without any special preparation in the plan.

First Cost of Plant.—This consideration, although really of the least importance among those enumerated, is distinctly on the side of subdivided power. The price of the high-speed engine per horse-power is now fully as low and generally lower, than that of slow-speed engines. Cost of foundation is materially less, as is also cost of erection and handling for repairs. There then comes into the question the clear saving of all the money invested in countershafting, pulley blocks, heavy belting, clutch pulleys, pulleys, and similar devices. In the station to which we referred above, the extra transmitting devices necessitated the investment of a sum not less than $6,500. The price thus expended would be sufficient to purchase practically 500 horse-power of independent engines,

Digitized by Google

adequate to generate 6,000 lamps, showing practically net earning capacity of at least $18,000 per annum. When we contrast this with the net losses due to the system of concentrated power, as above discussed, it leaves no room for argument as to the advantages of independent engines in electric light work.

A NEW PATTERN OF REFLECTING GALVANOMETER, WITH LAMP AND SCALE.*

BY G. L. ADDENBROOKE.

The instruments which I am about to describe are the outcome of improvements and modifications which have suggested themselves from time to time as the result of a good deal of experience in electrical testing for telephonic, electric lighting, and general experimental purposes. As usually constructed, the reflecting galvanometer is essentially a laboratory instrument, demanding care and skill for its management, besides being costly. Perhaps the greatest objections to it are, however, the difficulty of moving it and setting it up, and the time usually taken to put it right when it gets out of order. When, however, it is in good working order there is so much satisfaction in working with it that one returns with reluctance to the use of other instruments.

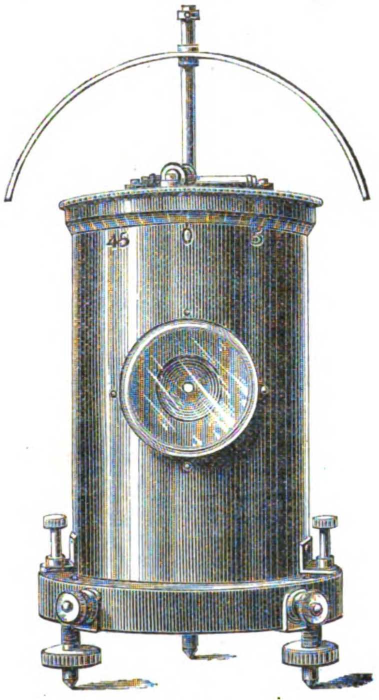

FIG. 1.

In the instrument before you it has been my aim, while preserving to the full the sensitiveness usually obtained in good laboratory instruments, to simplify and alter the construction, and thus fit it better for everyday needs, without at the same time diminishing its efficiency for the work with which it is now more particularly associated.

It is constructed as follows :—Fig. 1 shows the instrument complete. The base is circular and 5in. in diameter. The case is of brass, its top being 6in. above the base. The adjusting magnet, which is removed for carriage, rises 8in. further. The instrument is thus very small and compact. The adjusting magnet works up and down on its rod, a slot in the rod preventing lateral movement. Lateral movement is provided for by rotating the top of the case, which is marked with degrees so that the magnet can always be brought back to the same position again directly if it is necessary to move it. The spirit level or levels for setting the instrument are on the top of this lid. The case itself is provided with two L pieces at the bottom engaging in two screws with milled heads on the base. By giving them half a turn, and rotating the case slightly, it can be lifted off.

Fig. 2 shows the appearance of the instrument when the case is taken off. Rising from the base are two parallel uprights of ebonite ; four brass rods pass up through these, holding them in their places on the base, and forming the means of connecting the terminals with the wire on the bobbins. Further, there are four small thumb screws, which will be seen near the top of the ebonite uprights, two on each These screws pass through the brass rods I have mentioned, and into the outside cheeks of the bobbins.

The shape of the bobbins will readily be seen in the figure. The outside cheeks are left much thicker than the inside, and all the cheeks project about ⅛in. beyond the coils of wire. The lower halves of these projecting cheeks are cut away at the sides, as can be seen in the figure, leaving the upper portions projecting, so that the coils rest on the projecting portions on the ebonite uprights and slide exactly into their places. The cut-away portions of the thick ends of the bobbins are faced with brass plates, to which the ends of the coils are soldered. The thumb-screws above mentioned screwing into the brass plates complete the connections and hold the bobbins firmly in their places.

Both bobbins can thus be taken out in a moment without disturbing the needle ; there are no awkward connections to make or to get out of order, and if desirable several sets of bobbins can be made, wound with different lengths and sizes of wire to fit the same instrument, which can be interchanged without trouble at any time.

Now we come to the needle. The suspension is of quite a different type to that usually employed. A brass hoop will be observed passing over the centre of the bobbins and screwed at either end to the ebonite uprights. The whole galvanometer is put in the lathe and a very small hole bored centrally through this brass hoop. A V-shaped slot is then cut in the brass hoop from the front towards the back of the instrument, the point of the V-groove ending in the small central hole. About half an inch on each side of the hole two brass uprights are fixed ; they are forked at the top, and hold by friction a little ebonite rod with milled heads at each end.

One end of a silk fibre is attached anywhere on this rod, the other end is attached to the needle. The fibre may be a yard long if desired. The ebonite rod is then turned, winding the fibre round it until it (the fibre) is about the right length, and then the ebonite rod is slipped into its place.

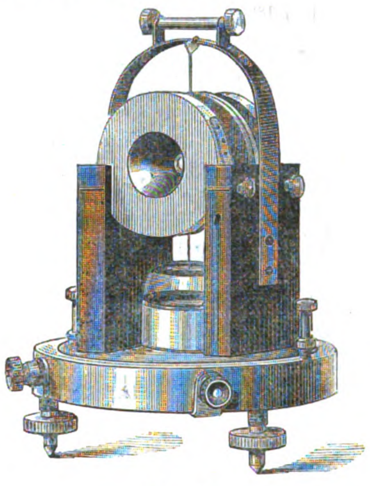

FIG. 2.

The fibre then, if it is wound the right way round the rod, at once automatically centres itself, and by rotating the rod the needle can be set exactly. By this means a long suspension is secured, and, if it is desired, several rods and needles can be kept for different purposes—say, one with damper for general use, and a finely-balanced astatic one for delicate testing, and a ballistic needle for condenser work. When the instrument has to be carried about a great deal spare needles, ready suspended, can be kept and be put in in a minute at any time should an accident happen. If the suspension of a needle does break it is often at a critical moment when time is important. To replace it is, as usually suspended, as, a rule, a long and tedious job. Much valuable time may therefore be sometimes saved by the use of a suspension of this character. It will readily be seen that attaching a new fibre is a very simple and short operation as compared with that necessary with the ordinary type of instrument. The needle itself consists of a stiff aluminium wire, carrying the magnets and mirror.

For all ordinary testing work I prefer to bend the lower end of the aluminium wire round into a loop and flatten it out. This makes an excellent damper ; it is sufficient to prevent long swinging and annoying vibrations without rendering the instrument dead and sluggish. This damper works in a little glass jar, fixed in the base of the instrument. The jar has its edges turned over to prevent the liquid being spilled when carried about.

* Paper read before the Physical Society, March 10th, 1888.

Digitized by Google

It is, of course, easy to add a second pair of coils on the same principle as the two in the instrument before you should it be desired, but a constant of 1° deflection with 1 volt through 1,000 megohms can easily be got with a single pair of coils, which is more than sufficient for most purposes.

In using reflecting galvanometers a lamp and scale are required. All who have had experience in working with such instruments know that there is often as much trouble with the lamp and scale as with the galvanometer.

In the lamp and scale I have here I have tried, while securing the maximum efficiency, to reduce the whole within as small a compass as possible. The lamp itself consists of a copper tube about 12in. long and 4¼in. in diameter. The bottom of the tube forms the reservoir, the top portion acting as a screen. This tube is supported by guides at the sides attached to a metal base, which permit of the lamp being moved up and down through a total range of 6in.

In order to fill the lamp easily a funnel is provided in the top of the reservoir, with a tube attached, which reaches nearly to the bottom of the reservoir. In this way the lamp can be quickly and cleanly filled, and there is no need of a screw stopper to keep the paraffin from spilling or evaporating.

Most essential points in the construction of a lamp are that the longer axis of the flame and the axis of the lens or slot should coincide, and, further, that the intensest part of the flame should be opposite the centre of the lens. In this lamp, by prolonging the

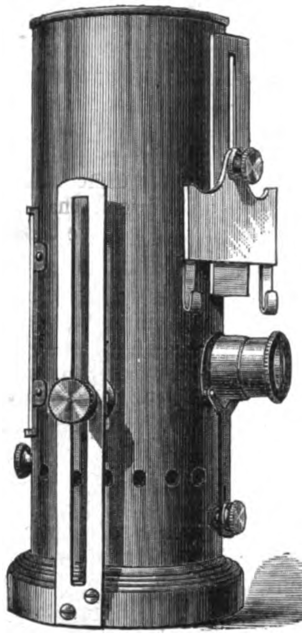

Fig. 3.

rod carrying the milled head for adjusting the wick and causing it to fall in a slot in the tube just below the door at the back, the longer axis of the flame is always kept in the proper place. Again, the height of the burner is carefully adjusted to be right when the lens is in a horizontal position. Further, to allow the lamp to be used in various positions, and with different instruments, the lens tube is made adjustable through a considerable angle, its axis of rotation being the centre of the flame. In this way a beam of light can be thrown upwards or downwards as well as in the horizontal direction. This is in working often a matter of great convenience.

For use with the lamp I have arranged a specially portable scale and shade. The scale itself consists of ½ a metre divided into millimetres. It is mounted on a thin board, as usual; this board is attached to a shade of the same length by long hinges. The whole is then cut through the middle, and a hinge fixed on the back of the shade. By this means the whole folds into half its length. Guides are fixed on the back of the scale, which engage in hooks fixed to a cross-piece on the front of the lamp, so that the scale slides easily backwards or forwards, and means are provided for raising or lowering the scale by itself, which is often convenient.

For carrying about or putting on one side, a box is arranged to take both galvanometer and lamp, with room for shunts and other accessories. The size of this case is rather less than is required for the ordinary pattern of lamp alone.

The maker of the instrument is Mr. J. J. Hicks, of 8, 9, and 10, Hatton-garden.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 3rd*, 1888.

THE CONVENTION AT PITTSBURGH.

It is thought by those who attended it that the recent meeting of the National Electric Light Association at Pittsburgh was one of the most interesting of the seven that have now been held by that body. The papers and discussions, which are all probably before you now, were generally marked by practicality, and gave the members many points to consider and work out in their stations and steam plants. Even where the topics were familiar and hackneyed, as in the case of underground wires, the evidence adduced by the speakers as to success or failure with burying the wires was most pertinent and valuable. The net result of the experience cited is that, while with incandescent lighting good work is being done with underground wires, including those in use on the alternating system, great trouble is still encountered with the high potential arc wires, no matter what precautions may be adopted. It was generally felt that to say arc wires could not be put underground was to make an unwarranted admission, and to limit the possibilties of the electrical arts; yet, on the other hand, few were ready to affirm that the satisfactory solution of the problem had been reached. The good point was made, too, that in this respect, judging from the numerous repairs of gas mains found necessary in every large city, and the many leaks which render the streets so odorous, our gas friends are, in fact, not so far along in overcoming the difficulties of perfect conduction as are electricians. It was further shown that the gas that thus escapes is one of the worst enemies underground wires have; and an explosion in the new telephone conduits at Buffalo came in time to emphasise the criticism.

The convention brought out a number of papers on the alternating current system of distribution which, together, present a number of facts, some of which are of decided interest at this time, when that method is becoming so prominent. The first paper read upon this subject at the convention by Mr. Philip Lange was devoted to the question of the general effect of powerful currents upon watches, and Mr. Lange showed, as the result of experiments, that the alternating current had no effect whatever upon the time keeping qualities of a watch; in fact, that the presence of the alternating current was conducive to the removal of any magnetism which might be inherent in the watch, produced by other causes. He described a ready method by which the watch affected with magnetism might be cured by simply placing it within a coil attached to an alternating-current circuit, and leaving it therein for a short time. This, of course, is a well-known experiment, which has often been applied to the demagnetisation of watches, but Mr. Lange laid particular stress upon the point that the alternating system provided a ready means at hand for watchmakers generally. Dr. Otto A. Moses drew attention to the fact that according to his view the continuous current on board ship was highly dangerous, as it affected the compasses, and thus made the steering of the ship unreliable; but Mr. Colvin, formerly in the U.S. navy, promptly replied that no such danger was to be feared from the direct current, and that experiments had conclusively shown that under many conditions tried on board the U.S. ship "Trenton" the running of the dynamo and lights had absolutely no detrimental effect upon the compasses.

In a paper "Upon the General Distribution of Electricity by Alternating Currents," by Mr. T. C. Smith, the author brought out some very pertinent facts in regard to this method of distribution, and asserted that there was absolutely no reason why in a properly constructed plant the converters should not be placed inside houses, and the secondary circuits be distributed therefrom. As regards the reliability of the converters to burning out, he said that of 600 converters of all sizes, from five to fifty lights, in an experience extending over twelve months of constant service there were only three actual cases of burning out, two of these being

Digitized by Google

5-light converters and one being a 50-light converter. The two 5-light converters were simply slowly roasted out from overloading until the insulation on the primaries was charred through, when the fuses flew out and all was over. In the second case it was a 50-light converter which was affected by an overload, due to the negligence of some one who had, instead of placing fuses in the converter, connected them up with solid bars of copper. In his entire experience there had not been a single case of connection between the primary and the secondary, or the primary and the shell of the converter, even in the case of the burning out of converter. Mr. Smith stated that when the system was first installed by him it was customary to "bank" the converters; that is to say, to connect all the primaries and all secondaries in multiple and distribute from this one wire. But two or three peculiar experiences have led him to change this plan. In several instances one converter of the bank for some unknown reason would blow its plugs, thus overloading the others; then perhaps another would give way, and thereafter the rest would go in quick succession. His method now is to let each converter carry its own load independent of the others.

A curious thing remarked by him is that the wires carrying the alternating current do not blacken or collect dust upon the surface on which they run. Thus, in their station circuits at Pittsburgh, where they have both the direct arc and the alternating current side by side, the ceiling is painted in very light colours. The paint under the direct-current wire is found to be very dirty in the usual way, and the wires themselves are covered with black deposit; while the alternating-current wires and the ceiling against which they lie are said to be as clean as the day when they were put up. Mr. Smith laid particular stress upon the fact that with proper insulation the alternating high-potential system could be made as safe as any other.

Another very interesting paper was that of Mr. O. B. Shallenberger on the energy of alternating currents. Mr. Shallenberger showed that where considerable lag existed in the circuit a large part of the energy of the current was returned to the circuit, and though the indicating instruments might, under certain conditions, show a large consumption of current, the actual power measurements showed that the power consumed was far less than their indications would seem to show. He gave as examples several instances similar to the one brought out by Mr. Stanley some time ago, in which the voltmeter connected to an alternating circuit with an induction coil shunting a lamp showed a higher E.M.F. than a single voltmeter placed across the main wires. Mr. Shallenberger maintained that retardation of one-fifth of the phase restores one third of the apparent energy to the circuit, and beyond this point the proportion restored increases in a still higher ratio. This effect, however, would only take place when the load was very small or the secondaries were entirely open; but even with moderate loads that effect was not produced.

Visits were paid by many of the delegates to the Bentley-Knight electric road, which has been built up the steep sides of Observatory Hill in Allegheny City, across the river from Pittsburgh. This road ought to be popular, for in its tortuous windings it certainly answers to Coleridge's description of the road that human beings love to travel. This piece of enterprise has already been referred to in my correspondence, so I need not go again into details. I may remind your readers, however, that it is partly conduit and partly overhead. At present over two miles are in operation, with grades up to 10 per cent. In the more remote portion some of the rails in the new ground have spread; but that section will be ready, too, very shortly. It is worthy of note that, while provision is made for coal consumption, the generating plant uses natural gas as fuel, the cost being only 6s. 8d. per day, or 3s. 4d. for each car now in service, and proportionately less as new ones go into operation. This cheapness of fuel compares with that at Scranton, where the electric road is trying to consume the mountains of culm at the rate of 5d. per ton.

Among the attendants at the convention were Prof. George Forbes and Mr. Anthony Reckenzaun, both of whom participated actively, and were quite at home with their energetic American friends. It is said that both of them contemplate an early return to England.

The Institute of Mining Engineers has just held its annual meeting at Boston. Among the subjects brought up was the employment of electricity in mining operations, introduced by Mr. G. W. Mansfield, who was associated with Mr. Leo Daft in some of his earlier work, and is now connected with the motor department of the Thomson-Houston Company. Mr. Mansfield's paper dealt with the various items of haulage, telpherage, excavating, drilling, pumping, ventilating, &c., and created a very favourable impression. One of the speakers stated that in consequence of the success obtained by the Pennsylvania Railroad Company with the Schlesinger system in their Lykens Valley coal mines, it was the intention to adopt electricity also for the coal mines in which he himself was interested.

In this connection an important contract made by the Sprague Company deserves mention. It is the distribution of current for power on an 18-mile circuit, on the Feather river, Butte County, California, to drain the bed of the river, where gold untold lies in the pockets and shelves. A tunnel has been drilled 12,000ft. long, leaving the bed bare around three sides of a lofty mountain. To supplement the draining operations, electric motors are to be put in at fourteen places for pumps, hoists, &c., using for prime power the fall of 300ft. near the tunnel through which the river has been diverted. The apparatus has to be very compact, so as to allow of removal in case of sudden freshets from the mountain streams, and, as a whole, the work involves many difficulties calling for high engineering skill. It is understood that the Sprague Company will resort to potentials far above those it has hitherto used in its motor service.

Our literary periodicals have recently been paying to electricity the homage of their attention, and the outcome must be beneficial in a great many ways. Mr. Frank L. Pope has contributed to *Scribner's Magazine* for March an admirable article on "The Electric Motor and its Applications," and I hear that he is to have another, on the telegraph, in the April *Century*. Not to be behind, Harpers have just published in their *Weekly* an excellent and profusely-illustrated description, by Mr. Schuyler S. Wheeler, of some of the modern developments of electricity; and the *North American Review* has printed an article by a French writer on animal magnetism.

We are all watching with anxiety the course of the copper market, and while we can send no good news as to a fall in price will be very glad to be cheered up by any such intimation from your side. The statement is made that four of the largest manufacturers of copper wire for electrical purposes in this country used 13,500,000lb. of copper in 1887, while in 1886 their requirements were only $10,000,000.

I notice that the Wall Street papers are exercising their ingenuity over the sudden departure of Mr. George G. Ward, manager of the Commercial Cable Company, for Europe. Mr. Ward is so well known in financial and commercial circles that as soon as his trip became known, the newspaper scribes tried to find reasons for it in connection with the cable war. The current idea is that Mr. Ward is to take part in a conference to be held in London, in which Mr. Gould will also join, and from that it is argued that cable stocks are a "good purchase."

NOTES FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

In electrical circles, so far as talking goes, there is at present much animation, though very little actual work is being done. The Municipal Council still pretends to be well disposed towards electric lighting, but this is totally in opposition to the actual behaviour of the administration when any definite scheme is brought before them; in fact, the regulations for the laying of wires under the streets are so ridiculous that if they are not radically altered no distribution can be seriously undertaken. The general idea is that these difficulties have purposely been thrown in the way in order

Digitized by Google

to prevent anything being done by private companies, the municipality intending by-and-bye to undertake the general lighting of the city on their own account. On Tuesday last a special committee of the council witnessed some experiments with the Gaulard-Gibbs transformers. Another experiment on a larger scale with the same system will be made in a few days at the Hotel de Ville. The council has already decided to erect a station of their own at the Halles Centrales for about 20,000 lamps, and it is highly probable that transformers will be adopted.

Most of the electrical papers publish in full the terms of the agreement made for the electrical lighting of the 1889 Paris International Exhibition. It can be briefly summarised as follows: The contract is made between the Ministre du Commerce et de l'Industrie and M. H. Fontaine, of the Gramme Compagnie; M. Lemonnier, from Sautter, Lemonnier et Cie.; M. Pol Tabry, of the Compagnie "L'Eclairage Electrique," and M. L. Rau, of the Edison Company, acting for the International Syndicate of Electricians.

About 1,500,000 candle-power will be provided, requiring 3,000 horse-power, the area to be lit extending over 300,000 square metres. The syndicate will receive as payment one-half of the amount taken at the gates in the evening, the entrance being fixed at 2fr. on week-days and 1fr. on Sundays. The capital is divided into 300 shares of 1,000fr. each, which are open to electricians of all nations. Every subscriber will have to erect an electrical plant equivalent to 10 horse-power, and to maintain it at work every evening during the exhibition. The motive power will be furnished by the syndicate. Any further information may be obtained from M. H. Fontaine, chairman of the syndicate, 15, Rue Drouot, Paris.

On the 1st of May next "the Restoration of the Bastille and the Rue St. Antoine," as they were in 1879, will be opened to the public. This exhibition will be lit with 1,000 incandescent lamps and 50 arcs. The motive power has been supplied by Messrs. Ransomes, Sims and Jefferies, of Ipswich.

The manufacture of incandescent lamps in France is being rapidly extended. The Woodhouse and Rawson Company have now got the works near Dieppe in full swing, and I hear that the Rothschilds Company will shortly undertake the manufacture of the Cruto lamp in Paris. Electric lighting in the provinces makes more rapid progress than in Paris, and before the end of the present year the towns of Montpellier, Perpignan, Marennes and some smaller places will be lighted electrically. The city of Havre has invited tenders for electric lighting to be returned by the end of the present month. The lighting of Mende, the chief town of the Department of the Lozère, will be started on the 1st of next month.

CORRESPONDENCE.

SAFETY DEVICES WITH TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the very interesting and able discussion of types of transformers given by Mr. Kapp in your late numbers, he credits Mr. Kent with having devised the simple apparatus of a "dividing sheet" grounded and placed between the primary and secondary coils of a transformer to intercept leakage from the primary to the secondary coil.

This "dividing sheet," or leakage shield, was, I believe, first described by me in United States Patent No. 322,138, dated July 14, 1885, in which patent there was explained the expedient of grounding the secondary itself to render them safe from leakage effects from the primary.

I quote from the patent as follows:—"It is not essential that the ground connection be attached to a secondary coil or circuit of a secondary coil, as it may be attached to a separate conductor, suitably interposed as a sort of diaphragm between the secondary and primary coils, although insulated from or in connection with the secondary itself." After reference to the figures showing the device, it goes on:—"The disc constitutes a metallic septum, insulated from the primary and insulated or not from the secondary; and by it any leakage from the primary, which would otherwise go to the secondary and connections, is intercepted and carried to the ground."

Near the close of the specification is the following:—"It is manifest that where, as in Figs. 2 and 5, the ground connection is made to a metallic diaphragm, interposed between the primary and secondary coils, an equally efficient, if not more efficient, protection from effects of leakage from the primary will be obtained." The patent fully describes the use and operation of the device in various forms.

As matter of interest in this connection, and as presenting a different protecting device, I may mention that in U.S. Patent No. 327,039, filed February 8th, 1884, I have described a connection of high resistance from the secondary to ground, in which connection is an electro-magnet, acting, when the primary leaks to the secondary and to earth, to cut off all connection of the local line with the leaking coil by a suitable switch. In this case the electrostatic capacity of the primary line and its unavoidable general leak will provide a sufficient current to earth through the switching magnet, when a connection has formed between the primary and secondary of a transformer. Prior to the production of such safeguards I never regarded inductional systems with high-potential primaries and low-potential secondaries as complete enough for practical use unattended with considerable risks.—Yours, &c.,
ELIHU THOMSON.

Lynn, Mass, Feb. 27, 1888.

THE SPECIFIC ELECTRIC RESISTANCE OF MANGANESE STEEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: An editorial note published in your last issue (March 9th) displays so singular a lapse of editorial memory that perhaps you will permit me to call attention to it. You state that from a paper you publish "in this issue it will be seen Dr Fleming has determined the specific resistance of manganese steel, and finds it to be 3¼ times as great as that of German silver." If you will turn to your own columns for November 4th last, you will find you have already published precisely the same scientific fact, only in that case the determination was made by myself, twelve months prior to Dr. Fleming, and formed the substance of a paper read by me before the British Association at Manchester. You were good enough to reprint separate copies of my paper, one of which I enclose.

Dr. Fleming's paper contains a serious omission, as no mention is made of the composition of the manganese steel he used, which may contain from 12 to 20 per cent. of manganese, the resistance of the material varying accordingly. Otherwise his paper appears to be almost a transcript of my own, of the existence of which no doubt he was unaware. My determination gave rather a higher specific resistance than his, viz., 75 microhms (legal) per cubic cent. at 15° C., with a temperature variation of 0·136 per cent. for 1° C., through a range of 200° C.—Yours, &c.,
W. F. BARRETT.

Royal College of Science for Ireland,
Dublin, March 12, 1888.

[We usually rather pride ourselves on our recollection of everything that appears in this journal; but Jove himself nods at times, and on this occasion we must plead guilty to the charge of forgetfulness which Prof. Barrett brings against us. We can only add an expression of regret that we should have overlooked the paper read by Prof. Barrett before the British Association in September last.—ED. *E.*]

THE TEMPERATURE AT WHICH NICKEL BEGINS SUDDENLY TO LOSE ITS MAGNETIC PROPERTIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When my paper bearing the above title was read at the Physical Society, Mr. Mordey asked a question which has an important bearing on the application of nickel to thermo-magnetic generators, and which I am afraid I did not at the time answer sufficiently. Mr. Mordey observed that in some experiments of his, after the withdrawal of the flame, a perceptible time elapsed before the nickel became magnetic. Mr. Mordey had evidently raised the temperature of the nickel too much before removing the flame. The metal should not be permitted to rise in temperature above a certain point, nor to fall below a certain point, if used for the purpose in view. With one of the specimens of nickel used by me the metal practically lost its magnetic properties at a tempe-

Digitized by Google

rature which varied from about 340° C. to 400° C., according to the strength of the magnetising force. It *began* to lose rapidly its magnetic properties at about 300° C., and if I had been using it for a thermo-magnetic generator I should have endeavoured not to let the temperature fall below 300° C., nor to rise above 320° C. Between these limits the loss or gain of magnetic permeability was nearly proportional to the rise or fall of temperature, and was very considerable even for a variation of 1° C. Probably the best way of regulating the temperature in practice would be first to gradually adjust the burners with the machine at rest until the nickel has nearly ceased to be magnetic, and the temperature is fairly constant; then to allow the machine to work, and again to adjust the burners until a maximum effect is obtained. It is not necessary that the nickel plates should be very thin—they might be ½in. thick, or perhaps more, with advantage; but it would probably be better to use pure nickel rather than the ordinary nickel of commerce, as it would appear from the experiments which I have already made that for high magnetising forces the rate at which the permeability diminishes with rise of temperature above 300° C. is greater for the former than for the latter.—Yours, &c., HERBERT TOMLINSON.

BATTERY *v.* ALTERNATE-CURRENT TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I had more than one reason for not giving full figures in support of my argument in favour of "transforming by means of accumulators" at the recent meeting of the Society of Telegraph-Engineers.

I prefer to bring these figures forward in a paper of my own, where I should have the right of rejoinder after they have been thoroughly criticised by others. You are perhaps aware that I intend to deal with the subject in a paper I am to read before the Society of Arts in May, and I trust that the Council of the Society of Telegraph-Engineers will be able to find room for a short paper on the same subject during the present session, so that everyone interested in the subject will have ample opportunity of criticising my figures and forming his judgment thereon.—Yours, &c.,

March 12, 1888. R. E. CROMPTON.

SERIES AND PARALLEL TRANSFORMER CONNECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Bernstein has pointed out to me that in the discussion of Mr. Kapp's recent paper on transformers I misunderstood his remarks (Mr. Bernstein's) on the question of the relative position of the mains in series and in parallel working. The passage was as follows:—"If they used transformers in parallel, they were obliged to use two main conductors, between which there was a very high difference of potential, say 2,000 volts; and they were, further, obliged to put them very close to each other in order to prevent induction on other wires. This made the insulation exceedingly difficult. Where they had transformers in series they only had the highest difference of potential at the dynamo end of the line."

Mr. Bernstein did not intend to convey that in series working it was less necessary than in parallel working to place the mains close together, but only that there was less danger of leakage or short circuit in the former than in the latter.

As I alluded to this point in my remarks, I gladly take the opportunity of correcting any misapprehension I may have caused as to Mr. Bernstein's meaning.—Yours, &c.,

March 14, 1888. W. M. MORDEY.

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In further answer to Mr. Pollak's question in your issue of the 2nd inst., with reference to Prof. Ayrton's Patent No. 783 of 1881, we beg to say that that patent is at present controlled by us, and that we are well aware of its importance as covering all systems—whether in parallel or in series—that take current from "points of contact" instead of from continuous conductors, and thereby surmount many of the difficulties inherent to the latter method of transmitting power.—Yours, &c., ERNEST BERGHOLT,

Secretary to the Series Electrical Traction Syndicate (Limited).

11, Queen Victoria-street, London, E.C., March 14, 1888.

STREET LIGHTING IN ENGLISH TOWNS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Could you, without much trouble, furnish me with a list of all the towns in Great Britain which are using electric lights for lighting the public roads?

I have looked over many back numbers of your journal, but do not find what I want.—Yours, &c., J. O. S. ELMORE.

Bombay, Feb. 24th, 1888.

[We believe that the following brief list is a complete one:—

Taunton (Thomson-Houston system),
Hastings (Brush system),
Blackpool (Siemens system),
Waterford (Thomson-Houston system),
Exeter (Thomson-Houston system).
Eastbourne (Brush system).
Greenock.

There are, of course, a large number of private arc lights exhibited in the public streets.—ED. *E.*]

THE DE KHOTINSKY INCANDESCENT LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 2nd inst., in "Notes," under the title "Seel Lamps," it is remarked that "the method of manufacture of De Khotinsky lamps is kept secret for reasons easily guessed at." I will ask you to explain this suggestion, as the meaning of it is not clear.—Yours, &c.,

(CAPT.) A. DE KHOTINSKY.

Rotterdam, March 7, 1888.

[We have pleasure in complying with our correspondent's request, although our remark had no very profound signification, and we still think its bearing must have been obvious to most readers. We may premise, however, that we know absolutely nothing of the method of making the De Khotinsky lamp, and do not in the least imply that it is a copy of anyone else's manufacture. Still, the fact is undeniable that the lamp in question either is or is not novel. If it is new, then we think that the makers are well advised in keeping their methods secret rather than acquiring patents. On the other hand, if it is not new, or if there is any degree of uncertainty on that point—well, then they are following other well-known examples of a similar character. We repeat that there is no reason whatever, so far as we know, to take the latter view; but we hope we have now made our meaning perfectly clear.—ED. *E.*]

THE STABILITY OF TELEGRAPH WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: One last word with Mr. Caws. If he wants to know the practice of telegraph engineers with respect to temperature, elasticity and form of suspended wires, it would be wise to consult the text-books. One of the best is Douglas's "Manual of Telegraph Construction," where this question is thoroughly dealt with. The fullest and earliest is "Blavier" (1852), who even discussed the use of springs. Mr. Edwin Clark showed us, thirty-six years ago, how to ignore the coefficient of elasticity in our calculations. Perhaps, in time, Mr. Caws will even understand my tables—tables by which copper wire is being erected all over the world.—Yours, &c.,

W. H. PREECE.

Digitized by Google

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I agree with Mr. Higgins in his letter to your journal of last week upon the above subject. The burden of accumulated snow and ice upon the wires cannot of course be relieved by any kind of spring, but I think it would be worth while by such means as I have already suggested to endeavour to prevent the wires from chafing close up to the insulator. Mr. Higgins, I think, found as I did in the snowstorm of January, 1887, that the wires broke "short up;" therefore had rubber compensators been in use many wires would probably have been saved. In that storm the wind was not blowing upon the wires at a steady pressure, but came in severe squalls, causing shocks, and these shocks, having nothing to receive them except the weakened ends, at the insulator, caused the wires to give way; consequently the supports, through being relieved of their strains of the span, were torn from their position by the next span in the opposite direction.

In reference to Mr. Caws, I think it very bad form on his part to become personal when corrected; in fact, it is as great a mistake as his methods to determine the stability of a telegraph wire if possible.

My address I willingly append, not that I am desirous of any communication with Mr. Caws, except with your kind permission through your journal.—Yours, &c.,

ROBERT T. BOZON.

144, Kennington-road, S.E., 12th March, 1888.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Higgins is unquestionably right in arguing that in cases where the existing wire is stronger than its supports the line would not be rendered more storm-proof by still further strengthening the wire, and leaving the support as before.

It is not the vertical pressure of the snow-cased wires which brings down the supports; their collapse is attributable to the oblique transverse stress, which results from the vertical pressure of snow and wire compounding with the horizontal pressure of wind.

It is possible, for example, that in a 100-yard span a single copper wire of 100lb. per mile may be encased with 40lb. of snow, which, added to its own weight, would make, say, 46lb. dead weight per span. That snow-wreath may present a resisting area of perhaps 40ft. (measured normally to the direction of the wind), and the effective pressure of the wind may be perhaps 20lb. per foot (or very considerably more on rare occasions), so that the horizontal (wind) pressure would be, say, 40ft. × 20lb. = 800lb., while the vertical (dead weight) pressure would be only 46lb. The oblique (resultant) pull on the support standing between two such spans would (*if allowed to mature*) be $\sqrt{800^2 + 46^2} = 801$lb.; and it is to such oblique pressures (wholly or partially matured) that the collapse of the supports, which Mr. Higgins complains of, is due.

But wind is not a continuously uniform force. It moves in waves, whose period is greater or less in direct ratio to the velocity, and as the square root of intensity or pressure. The initial movement of each wave of wind is resisted by the inertia of the 46lb. dead weight; and, though this is followed by its own momentum, the duration of the wave of pressure may have been too brief to allow the catenary to be swung out to the full angle of deflection it would have reached had the wave pressure continued.

Electricians will understand me better, perhaps, if I say that, owing to inertia, the catenary, in deflecting transversely, lags behind the wind-wave which causes the deflection. If the wire were quite inelastic, and if the supports were absolutely rigid, the measure of lag would depend on the ratio of the weight moved (as the 46lb.) to the pressure moving it (as the 800lb), and on the period of oscillation due to the dip of the catenary. But with the elastic wire the lag is modified very materially by the extensions and contractions of catenary-length due to the alternations of wind force. Each extension and contraction needs time to mature; and if the period of the wind-wave is too brief to afford that time, the full extension or contraction, due to the alternations of wind force *per se*, is not permitted to mature. The smaller the lag the less the resistance, and the less the strain on the supports. It is easy to see that an elastic catenary has less lag than an inelastic one, and by its yielding to the wind it evades to a greater or less degree (according to the measure of its compliance) the *wrath*, so to speak, of the passing gust. It follows that, as there is less wind-stress thus resulting on the wire, there must, from the same cause (viz., the wire's extensibility), be correspondingly less wind-stress on the supports.

Therefore, the greater the extensibility of the wire, the greater the relief from storm-stress, not only of the wire but also of the posts or supports.

And inasmuch as, by means of spring shackles, a great importation of additional extensibility is secured, the supports benefit in the same measure as the line wire benefits.

Let us compare the telegraph post or support to the central stem or trunk of a giant elm or oak, and let us compare the wires to the branches. We know that the tree saves itself by bending to the blast. The trunk never bends so much as its branches. Some trees have trunks of extraordinary thickness and rigidity (as the finest specimens of the weeping willow, for example), but their branches are so extraordinarily supple as to fully atone for the want of suppleness in the trunk. Likewise if, through force of circumstances, the supports of a telegraph line cannot be made so supple as they ought to be, the spring-shackles will undoubtedly introduce the saving advantage of extra suppleness in the catenary, and of this extra suppleness the posts or supports will share the benefit to the full.

Moreover, by means of the spring shackle the insulation is so vastly improved that the same amount of conductivity as is now obtained from a 100lb. copper wire could be got from a lighter wire; and on the lighter wire there would be a lighter gathering of snow and a less wind force.

If I have not made my meaning clear I hope Mr. Higgins will write again.—Yours, &c., FRANK CAWS.

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At length the blow has fallen, and we have now another set of Fire Insurance Rules.

We have to-day seen a copy, and we presume that now not only will the Telegraph Engineers get out a set, but every individual insurance company will follow. What are contractors to do then? What will the public think? Surely if the society had only been content to adopt the well-known Phœnix rules, and embody them as their own (of course acknowledging their origin), all this trouble might have been averted.

Who can tell the amount of damage that will be done to our industry through the obstinate and irresponsible action of our presumably representative Society?

If a poll had been taken of the society's members, or of the electrical trade, would not the verdict have been in favour of letting well alone, and giving to the Phœnix rules (which certainly have the merit not only of priority but of secured success) the authority of the trade's society?

These are burning questions, and certainly require the immediate attention of every

ELECTRICAL CONTRACTOR.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

FIRE TELEGRAPHS.

At the meeting of this society held on Thursday, 8th March, the President, Mr. E. Graves, in the chair, a paper was read by Mr. Von Fischer Truenfeld on "The Present State of Fire Telegraphy." The paper, although highly interesting and important, was of an entirely non-technical character. The author presented a large number of statistics bearing upon the subject, and tending to emphasise the importance of fire alarms in securing the early extinction of fires. Tables 1 and 2, with the remarks appended thereto, probably contain the most important figures.

* Chimney and false alarms excluded.

† But not through accidents caused by drunkenness, upsetting of lamps, or such like causes, and not including men of the Fire Brigade.

▲ No classification obtained.

REMARKS.

Glasgow.—Street call-points were introduced in 1879. They are of Anderson and Munro's system. The "Lives Lost Record" does not sufficiently divide the causes of death. The low percentage of serious fires is due to the solid style of buildings, the stairs being almost wholly of stones.

London.—Street call-points were introduced in 1880. They are of the Exchange Telegraph Company's, Spagnoletti's and Bright's system.

Leeds.—Street call-points were introduced in 1884. They are of Somer's system. There is also telephonic communication between fire and police stations.

Bolton.—Street call-points were introduced in 1885. They are of Philips and Hurst's system. There are 72 cotton mills electrically connected with the fire-brigade station, which has also since 1882 been connected to the Telephone Exchange.

Nottingham.—Street call-points were introduced in 1882. They are of the National Telephone Company's system. There is telephonic communication between the fire stations.

Brighton.—No street-call points, but telegraphic communication is established between the whole of the police and fire stations. The Telephone Exchange is also utilised to a large extent for transmitting information of fire; but these Exchange call-points are not included in this list, although they have largely contributed to the reduction of serious fires.

Dublin.—In 1883 telephones were connected with the telegraph system, and they serve as street call-points, of which there were 12 in the year 1886.

Manchester.—No street call-points. "Serious fires" mean here such where 1-6th or more of the property was damaged or destroyed, hence the proportionately low percentage of serious fires. The official records of "Lives Lost" include persons accidentally catching fire, and the figures are therefore valueless for a comparison with the percentage of serious fires.

Liverpool.—No street call-points. No records of "Lives Lost" are kept. Up till 1882 17 fire stations were connected by telegraph. These stations are now supplied with telephones at a total number of 20 telephone stations.

Edinburgh.—No street call-points, but the fire stations are, since 1884, in connection with the Telephone Exchange. The very low percentage of serious fires is due to the substantial construction of houses and stairs, which are of stones.

Salford.—No street call-points. Stations are connected by telephone. "Slight fires" are here such as result under £2,000 damage. This explains the comparatively small number of serious fires.

Bradford.—No street call-points. The fire-brigade station is connected telegraphically with 7 police stations.

Bristol.—No street call-points.

Sunderland.—No street call-points. The fire stations are connected by telephone.

Oldham.—No street call-points.

Hull.—No street call-points. Fire and police stations connected by telephone.

Birmingham.—No street call-points. Till 1879 the fire-telegraph was in the hands of the police. The Gower-Bell telephone was introduced in 1881 for fire purposes only, and the National Telephone Company put an instrument at the chief fire station. At present police and fire brigade work the telephone on distinct lines.

Sheffield.—No street call-points. The fire station is in telephonic communication with the Telephone Exchange. The average number of fires for the last ten years has been 75.

Cork.—No street call-points. There is only one alarm-point at the only fire brigade station of the town.

Blackburn.—No street call-points. Only one single fire-brigade station. Serious fires where damages exceeded £1,000; all others treated as slight.

DISCUSSION.

Mr. S. SHARP said he would like to carry fire alarms much further, and bring self-acting fire alarms into all large warehouses, &c. He then described one which had been recently taken up by his firm, consisting of a small Bourdon gauge tube filled with ether, which made a contact when the ether was expanded by heat. He mentioned that one on the ceiling of a room 12ft. high was actuated in two minutes by lighting a dish of spirits of wine on the table.

Mr. CRAWLEY: A fire alarm box was recently sent to my firm, and as I thought it might be of interest I obtained the permission of the inventors, Messrs. Saunders and Brown, to place it on the table to-night. A number of the boxes at different points are connected in series on a single wire, and in each box is a pendulum which, when released by the handle being pulled, breaks and makes the circuit at a rate depending on its length—some two or three times a second in this one—no two pendulums on the same circuit having the same rate of swing. The line circuit, when it arrives at the station, passes through a high-resistance relay, a single-cell battery, and to earth. The circuit is always closed, except when broken by one of the pendulums at the posts. At each break the relay sends a strong current from a local battery through a series of as many electro-magnets as there are posts. Before the first magnet there is an iron pendulum of the same time of swing as the one in the first post; before the second magnet one corresponding to that in the second post, and so on. When the alarm is given it causes a series of breaks and makes which will cause the corresponding pendulum at the station to swing violently, while the others are practically unaffected. A bell also rings to call attention. As soon as the signal is received a strong current is sent to line which resets the pendulum in the box ready for the next call. If two boxes (or even three) call simultaneously, both receiving pendulums will vibrate, for though the circuit is often broken at one box when made at the other, yet when both *do* make together it is at such a time as to act on both receivers. A circuit of five of these boxes has been in use at Portland-road Fire Station for the last four years. Captain Shaw, however, has a preference for a system with a separate wire to each box, and of these there are some 70 instruments of Messrs. Saunders and Brown's design in use in London. The circuit is normally open till closed by the handle being pulled, it is then kept closed by an electro-magnet in the box. A short-circuiting bell then rings at the station, and an indicator drops; a short-circuiting bell also rings in the box itself. The circuit is then broken for a moment by the man on duty, and all is ready for another call. The bell at the box ceasing to ring acts as a "received" signal. Both these systems avoid all false calls from leakage or contact with other electric wires.

CAPTAIN SHAW also took part in the discussion, and expressed his high appreciation of the utility of street alarms. He thought possibly some improvement might be effected in the direction of minimising the possibility of giving false alarms, which were still a considerable source of trouble to the Brigade.

COMPANIES' MEETINGS & REPORTS.

The Pilsen, Joel, and General Electric Light Company (Limited).

An extraordinary general meeting of the shareholders in this company was held at the City Terminus Hotel, Cannon-street, on Tuesday last, Sir Rawson W. Rawson presiding.

The SECRETARY (Mr. W. H. Trentham) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, the memorandum which accompanies this notice really anticipates what I have to say to you on this question. When we met in November I expressed a hope that there was an amount of profitable business before us which would enable us to recover to a certain extent the capital which had been placed in this Company, and to yield a satisfactory dividend for the future to our shareholders. Each day has increased our sanguine hopes in that direction. Any one of you who may have been present at the recent meeting of the Society of Arts, where Mr. Carpenter gave an account of the present position and prospects of electric lighting, or who may have seen the printed report of his address, will be satisfied that there is a largely and daily increasing desire for the use of the electric light. We had hoped that that would have extended from the establishments into which it is now introduced, namely, trading establishments, private residences, and public buildings to street lighting, where particularly lies our interests; but it is pretty clear that that part of the business is not likely to be largely extended for two or three years at least. Therefore our chief object is to aim at extending our business in the direction of private installations. Many of you must be aware that several of the companies at present existing are doing a considerable amount of work in that direction. There is the Grosvenor Gallery Company, which has a very extensive business; there is the House-to-House Lighting Company, which has been received most favourably wherever it has advanced its efforts; there is the Kensington Company, which has been established at South Kensington with Mr. Crompton's light, and there are the Storage and other companies carrying on a system of lighting from central stations which promise the best results to them; and we feel that we should be wanting in our duty to our shareholders by neglecting the opportunity which now presents itself, if we did not extend what we have begun in this direction, being confident that with the careful and economical management under which it is now conducted, we can derive a satisfactory profit for the money actually invested in our operations. That is the reason for our coming to you for a call, to enable us to carry out that extension. We have now had the experience of six years' operations. Three years of that experience came under the old system, and the old hopes of extensive street lighting and extensive operations throughout the country—in lighting towns, villages, parts of the city, and so on. But during the first three years we spent money in provisional orders, in expensive surveys, and in manufacturing operations which have led to the expenditure of our original capital, and to disappointment; but as regards our lighting of private and trading establishments, our operations have been most successful. For the last three years we have not had a serious failure, difficulty, or complaint. Those who first took our lights have taken more of them. In the case of Mr. Baker in Holborn, who was one of our first customers, we have extended to him our lighting from Holborn to Fleet-street. From our new establishment in Stanhope-street we have lighted his establishment in Tottenham-court-road, and we have the opportunity of a large development of house and shop lighting in that district. We believe, therefore, that we are acting in the interests of our shareholders in making a call to complete what we have begun so successfully, and to extend our trade so that we may increase the dividend which, unlike most other companies, we have been able for two years to give to our shareholders—a mere trifle, certainly, but still no loss. That explains why we ask for additional funds at the present time. The second point that I have to bring before you is an explanation of our proposal for writing down the capital of the Company. Our patents originally extended over two kinds of lamps—arc and incandescent. Our interest in the latter has already been destroyed by the Swan and Edison Company establishing their patents in this country, and the value of the Gatehouse patent has already been written off. Then, with regard to the arc, we have been in existence now as a company for six or seven years, and the patents upon which we have been acting must have existed a year or two before that time. I do not remember the exact date, but half of the fourteen years of the life of our patents has already expired. We have only, therefore, seven years more of our patents to run. We feel that we are bound to take that into account in the estimate of our assets. We should not be justified in maintaining these patents at

Digitized by Google

the same value year after year. We may establish a certain goodwill that may be very valuable to us before the patents expire, and we may be able to prevent others from using our patents, simply because we may be able to make better lamps than anybody who would attempt to cut us out; we may be able to show our competency to make safe installations better with our acquired experience than any new rivals attempting to come into the field to oppose us; but, as Directors, we are bound to take into consideration what the value of these patents will be during the next seven years. That being the case, if we were to retain these patents, which we now value at £25,000—that is the figure at which they stand in our books—we should have to write off £3,000 a year for the next seven years. That being the case, we do not feel that we should be able to make such a dividend as would make it worth our while to continue the operations of the Company. Our profits would be swallowed up in simply keeping up the nominal price of our patents, and on that account we believe that it would be most advantageous to the Company to take as the value of their capital the money that is available for making installations under the present system such as the public desire. It is of no use our having patents which the public do not use; and we do not see, certainly for two or three years, the chance of the use of the arc lamp extending in Great Britain, or in those places where we hold the patent rights. The demand now is for many incandescent lamps and for a few arc lights. We possess the advantage of supplying to our customers one of the best arc lamps in existence, but we are obliged to provide ourselves by purchase with incandescent lamps to satisfy their wants, and the Directors, after having matureiy considered the matter, having no object in view but the interests of the shareholders (for I think you will all acknowledge that for three years we have been working with no other object but the general interests of the Company, having certainly a very small interest in undertaking the onerous duties of our post), wish to do the best thing for the Company; and we believe that what we now propose is the best thing to be done in the circumstances of the Company. If any of our shareholders see an objection to our policy which is insurmountable, and can offer a plan more conducive to the interests of the shareholders, we shall be most ready to adopt their views; but having had this matter under their most anxious consideration for a considerable time, the Board see at present no other course open to them but the one they suggest; and having consulted their legal advisers as to the best way of carrying out the measure they have brought forward this resolution, and request your acceptance of it. I do not think I have anything further to add; but I shall be glad to hear from any gentleman any suggestion that will be more profitable to carry into effect in the interests of the Company. I therefore, as a matter of form, propose this resolution:—

"*That if an order of the Court be obtained for confirming this resolution, the capital of the Company be reduced as follows:—*

"*(a) By reducing from £2 to £1 per share the nominal amount of the 3,517 shares of the Company of £2 each, which have been forfeited, and are now unissued.*

"*(b) By cancelling, as being capital which has been lost, or is unrepresented by available assets, the sum of £1 per share on the 24,483 shares of the Company of £2 each, with £1. 5s. called up thereon, being the shares numbered 1 to 28,000 inclusive, with the exception of those mentioned above in clause (a), and the sum of £1. 16s. per share on the 100 fully paid-up shares of £2. 5s. each, being the shares numbered 39,351 to 39,450 inclusive.*

"*And that the Memorandum of Association of the Company be modified so as to carry into effect this resolution.*"

Major SCRIVEN, in seconding the resolution, said that he would like, as a merchant, accustomed to accounts, to add a few words to what the Chairman had just told them. Some three years ago, when they started on a modified basis, the available capital from the sale of their plant—he did not want to go too far back in the history of the company—was only about £7,000, and on that amount they had earned a very fair dividend and profits. They now saw the chance of increasing those profits considerably, for which they required a small amount of extra capital, and, as the Chairman had told them, the Directors thought they should be wrong if they did not make the proposed call, and tell them that there was an opportunity of extending the business. But they were met with this difficulty, that if they called up further money they wanted to pay the shareholders a good return for it, and they had little doubt that they could do so, not only on the capital that they would call up but on the actual working capital they now had. The Chairman had explained to them that they could not in their opinion consider the value of the patent rights as a valuable or proper asset any longer. They might mix their patent rights and goodwill together, in which case it would perhaps not be so necessary to write them off provided their total income justified so large an amount as goodwill. Goodwill might be fairly purchased, if it was a sound business, at three or four, or even five years' purchase, but twenty or thirty years' purchase was not a proper asset in a balance-sheet for goodwill. Now if they wrote off this capital, not as lost, but as a non-valuable asset, which they saw was meant by the terms of their resolution, they would be able, he hoped, to show the shareholders a very large and satisfactory dividend on their reduced capital. Their shares at the present moment were at a nominal price. He fancied that any larger offer to sell would bring them to more than a nominal price—it would bring them to a very decided price indeed. He thought it was very much better to hold shares of the nominal value of 5s., paying probably 15 or 20 per cent. dividend, and see them rise to a premium, as they would, and be worth, say, 10s. each, than to have shares of the nominal value of £1. 5s. worth only 1s. 6d. That was really why the Board asked them to adopt the proposed policy. He was sure it was a sound one. It was, in fact, putting the capital of the Company at its real figure, and not deteriorating the property in any way whatever. If better times came round, and a good Electric Light Bill were passed, as he believed would be the case, and they had more scope for extending their patent rights and manufactures, those shares would go up in value in proportion to the profits earned. He firmly believed, as did the rest of the Directors, that not only was there no patent arc light equal to theirs, but he did not think it possible that one could be invented to beat it. He had thought so all along, and he still held that opinion.

Mr. JAMES FYFE adversely criticised the proposed policy of the Directors, who, he further maintained, had shown a remarkable inaptitude for carrying on the business of the Company. He did not believe that their property had deteriorated in value as the Board seemed to make out, and protested against their calling out stinking fish in the face of the whole world when other electric lighting systems were doing so well. He went on to show that in consequence of the reduction of the price of the Company's shares in November last two of the Directors (Major Scriven and Mr. Whately) had became disqualified to sit at the Board, and said that clearly the Directorate was utterly unorganised, and had been in reality non-existent for more than a year, and therefore could not, in point of law, carry out the policy they now suggested.

A SHAREHOLDER asked how many shares the Directors held.

Mr. WHATELY: I hold 100.

Mr. FYFE: Major Scriven and Mr. Whately both hold 100 shares, but that is not a sufficient qualification.

Mr. HUTTON: They must have a legal qualification.

Mr. FRANCIS S. SAMUEL: What is the legal qualification

The SOLICITOR: £250.

The CHAIRMAN said that the qualification was not determined by the number of shares they held, but by an amount of money, and that was £250, as they had just heard.

A SHAREHOLDER asked how long the Directors referred to had been deprived of their legal qualification.

Mr. WHATELY replied that it must have been since the shares were reduced last year. Personally, he was very pleased to learn the fact for the first time. At the same time, he must remind the meeting that he and his colleagues had worked very hard for the benefit of the Company. It was due to both them and himself to assure the shareholders that they had not sold any of their shares in the Company.

Mr. SAMUEL contended that as they had not been able to live with £7,000 there was no reasonable prospect that they would be able to live with £14,000. The arc light that they possessed was a very good one, but they could not do a practical business against the companies recently established with large capitals on so small an amount as they now possessed or would possess by the scheme presented to the shareholders. He therefore suggested, under the circumstances, that they should by tender sell their rights as a going concern to one of the larger existing companies, and thus secure the largest amount of money possible for their rights and property.

Mr. GILBERT concurred in this view of the case, believing that the capital at the command of the Company under the proposed arrangement would not be sufficient to enable them to do a business that would be profitable to the shareholders.

Mr. BENEDICT also endorsed this opinion, and thought that it would be folly to throw good money after bad.

Mr. FYFE thought that it would be premature to adopt the suggestion of Mr. Samuel, and sell the Company's interest, believing that they had a much more valuable property, in view of the growing demand for the electric light, than the Board were inclined to believe.

After a brief discussion as to whether the business of the meeting might be legally carried on in view of the fact of the disqualification of the two Directors named,

Mr. FYFE moved as an amendment to the original resolution:—

"*That this meeting be adjourned for a month, and that a committee of shareholders, consisting of Messrs. Hopkins, Gwynne, Hutton and Fyfe, be appointed to investigate the statements contained in the notice convening the meeting, and confer with the Chairman and late Directors, and to report thereon, and generally upon the business of the Company, at such adjourned meeting; that the secretary be directed forthwith to issue notices for a general meeting to appoint Directors in the place of the Directors disqualified, and that in the meantime the Chairman and the secretary be authorised to continue the business.*"

The Chairman and other Directors having expressed their approval of the amendment, it was put to the meeting and carried unanimously.

NEW COMPANIES REGISTERED.

CHARLES L. BAKER AND COMPANY (LIMITED).—Registered by Rowley and Co., 3, Great Winchester-street, E.C., with a capital of £25,000. Object, to acquire on the terms of a provisional agreement, dated the 19th of November, 1887, and made between Chas. L. Baker of the one part and Frederick Murgatroyd of the other part, with such modifications (if any) as the directors of the company may think fit, the business of the firm of Charles L. Baker and Co., telegraphic, electric, surgical, and scientific apparatus makers, of Worsley-street, Chester-road, Manchester, as a going concern, including or together with the goodwill of the said business, the right to use the style of the said firm, and all trade marks used in the said business, and the benefit of all pending contracts entered into by the said firm, and the lease of the premises in Worsley-street aforesaid, occupied by the said firm, and all patent rights, plant, utensils, stock-in-trade, work in progress, patterns, drawings, electros, fittings and effects owned by or belonging to the said firm in connection with the business. The first subscribers are:—

	Shares.
C. Baker, Cornbrook Telegraph Works, Manchester	1
J. Johnson Bennett, Seymour-grove, Manchester	1
G. W. Locock, 2, Brooklyn-villas, Old Trafford, Manchester	1
T. Pilling, 2, Booth-street, Manchester	1
F. Murgatroyd, 2, Booth-street, Manchester	1
W. Penman, 6, St. Bees-street, Manchester	1
J. Witham, 72, Bury Old-road, Manchester	1

The first directors shall be James Leigh, J. E. Longson, Thomas Horsfield, W. B. Lowcock, Charles Sacré, John Hugh Penman, John Knowles Glazebrook, and Charles Laurance Baker. Qualification, the holding by each of at least 250 shares in the company in his own right. Charles Laurance Baker shall be managing director at a salary of £500 per annum.

ELECTRICAL WORKS CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—This company was registered on the 2nd inst., with a capital of £2,000 in £1 shares, to carry on business as electricians and electrical engineers. The subscribers are :—

	Shares.
R. C. Heywood, 101, Darenth-road, Stamford-hill, accountant	1
S. Graham Willmott, C.E., 42, Old Broad-street	1
M. Vinning, 33, Alexander-road, Hornsey, retired naval officer	1
C. J. Muller, 4, Hercules-passage, E.C., stockbroker	1
F. Belcher, 9, Warwick-terrace, East Finchley, accountant	1
H. A. Kidd, 27, Kempsford-gardens, Kensington, insurance agent	1
G. A. Grindle, 19, Great Winchester-street, electrical engineer	1

Registered without special articles.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). This company was registered on the 2nd inst., with a capital of £100,000, divided into 19,980 ordinary shares of £5 each, and 100 founders' shares of £1 each, for supplying electric light and power in the district of St. James' or elsewhere in the metropolis. The holders of the founders' shares will be entitled to one-half the net profits remaining after payment of 7 per cent. per annum on the ordinary shares. The subscribers are :—

	Shares.
*Col. G. E. Francis, 55, Victoria-street, S.W.	1
*Latimer Clark, C.E., 6, Westminster-chambers	1
*E. M. Royds, Petersfield, Hants	1
*Peter Penn-Gaskell, J.P., 12, Albert-mansions, S.W.	1
Capt. E. M. Pallisen, 91, Earl's Court-road	1
Arnold Trinder, 47, Cornhill, solicitor	1
*E. J. A. Balfour, 32, Addison-road, architect	1

The number of directors is not to be less than 3, nor more than 8; the first are the subscribers denoted by an asterisk; qualification 100 shares; remuneration £1,000 per annum, or such larger sum as may be equal to 10 per cent. of the net profits, but not exceeding £1,500 in any year.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The directors have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, being the same distribution as for the corresponding quarter of last year. The traffic receipts of this company for the week ended March 9th amounted to £4,668.

DIRECT SPANISH TELEGRAPH COMPANY.—The directors of this company, upon the accounts for the half-year ended December 31st, 1887, being submitted to them, have decided, subject to the audit of these, to recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend of 2½ per cent. (free of income-tax) for the half-year upon the ordinary shares, making, with the previous distribution, 4 per cent. for the year 1887.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The accounts of this company to the 31st December last show, subject to audit, a balance of profit of £121,800, after payment of three interim dividends. The directors now propose to distribute, on the 26th April proximo, the usual dividend of 2s. 6d. per share, making a total dividend of 5 per cent. for the year 1887. It is also proposed to pay a bonus of 3s. per share, or 1½ per cent., making a total distribution of 6½ per cent. for the past year, against 6 per cent. in 1886. The balance of £53,000 has been carried to the reserve fund, which now stands at £620,000.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 9th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,881.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended February 29th, 1888, amounted to £3,139, as compared with £2,840 for the corresponding period of 1887. The receipts for November, 1887, estimated at £5,236, realised £5,314.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 514.—Vol. XX. FRIDAY, MARCH 23, 1888. Price 4d.

NOTES.

If the County Government Bill should pass into law in the shape now before the House, the powers at present exercised by the Board of Trade in connection with the granting of provisional orders under the Electric Lighting Act will be transferred to the new County Councils. It may fairly be presumed that, on the whole, such a change would operate favourably upon the development of electric lighting. Time will certainly be saved, legal expenses would probably be diminished, and a wider local interest would be aroused in the undertaking. On the other hand, it may be feared that vested interests will have much influence in the provincial tribunals, and it is to be hoped that under certain conditions an appeal will be allowed, either to the Board of Trade or to Parliament.

We believe that the decision of the Supreme Court of the United States, upholding the validity of the Bell telephone patent, has given general satisfaction in this country. Apart from the personal interest which Mr. Graham Bell established for himself by his visit in 1877, the overthrow of his American patent would be felt as a great inconvenience here, unsettling the English patents, and offering encouragement to fresh litigation. The accounts of the judgment, which was delivered on Monday last, are very meagre; but it is reported that the case has been decided "on its merits"—a circumstance to be thankful for in every way, not more on account of the invention than of the inventor, whose *bona fides* was recklessly impeached by the promoters of this law suit.

In granting the interim injunction against the Equitable Telephone Company in the action brought by the United Telephone Company for an alleged infringement of the Bell and Edison patents, the Judge laid down a point of some importance in Patent Law. The contention of the defendant was, that by delaying to take action for nearly two years the plaintiff company had condoned the infringement, if any. But the learned Judge laid down that no action for infringement need be brought until actual damage is sustained by the owners of the patent. If a man, he said, threatens to cut down a tree on your property it is not incumbent upon you to take steps to restrain him before he actually swings the axe.

It seems a pity that the active and intelligent (and above all successful) electricians of America should be subject every now and again to be puzzled and misled by the publication of some apparently authoritative document containing the latest dictum of the native Professors of science (though "falsely so-called"). We venture to think that in calling attention to these performances we are rendering some service to our very numerous friends on the other side of the water. Our wrath has been moved at the present moment by the perusal of a paper "On Electromotive Force and Difference of Potential, by Prof. H. S. Carhart," in the *Western Electrician* of the 3rd inst. We there learn that "it is possible even to have a circuit through which a current is flowing without any difference of potential in it." As an illustration we are led to consider the case of a solenoid into which a bar magnet is thrust. Then follows this extraordinary statement, "the loss of potential in passing over any portion of the ring, due to its resistance, equals the gain due to the induction, provided the resistance of every portion of the wire is proportional to its length." May we ask the Professor to recollect that the loss of potential due to the resistance of the solenoid is a function of the *current*, and that the current may be varied indefinitely by varying the external resistance, without affecting the impressed E.M.F. in any way? *Verb. sap.*

In a letter which we published last week a correspondent made known the fact that "at length the blow has fallen, and we have now another set of Fire Office Rules." We regret to find that in certain circles the gravity of this announcement has scarcely been fully appreciated. We have even heard remarks of an unduly flippant character upon our correspondent's weighty phraseology. We beg, therefore, to express our opinion that this is really no laughing matter, although, happily, even at the eleventh hour, there is some reason to hope that the threatened state of anarchy may not be of long duration. Everyone will be relieved to learn that the Fire Insurance Committee of the Society of Telegraph-Engineers has at length brought its protracted labours to a close. We are still more pleased to announce that Mr. W. H. Preece, the chairman of the committee, has undertaken at an early date to read before the Society a paper, in which the whole subject will be treated historically and theoretically, as well as from the practical point of view. On this occasion a very full house may be confidently anticipated.

We have commented in our leading article this week on the glaring deficiency of the British Navy in respect to telegraphic signalling. Lord Charles Beresford intends to draw the

Digitized by Google

attention of Parliament to an equally remarkable deficiency in the mercantile marine. Except to signal the name of the ship or for purposes of demanding assistance, the merchant service cannot communicate in any way with the ships of H.M. Navy The semaphore and Morse signalling systems of the latter are utterly unknown in the former. We agree with the late Junior Lord of the Admiralty that this lack of communication between vessels of the same nationality might be of serious consequence in time of war, and it furnishes one more argument in favour of popularising the Morse code.

THE publication of a Parliamentary return showing the receipts and expenditure on the Telegraph Service since its acquisition by the State has revived the old complaints of the excessive price paid for the businesses of the extinguished companies. It is pointed out, too, that whereas they made considerable profits, the Government has incurred and continues to incur considerable losses. The two complaints are inconsistent with each other ; but the fact is, that these yearly deficits are not due to the original cost of the business, but to the unremunerative tariff on which the Post Office was for 14 years compelled to work it. Whether the sixpenny rate will prove more profitable still remains to be seen. But it cannot be too often repeated that it is the public who demand these concessions from the State, and that if they do not turn out well the public and not the State is to blame.

IT may be hoped, however, that with this lesson before them the Government will take care not to pledge themselves to any heroic reductions of the tariff when asking Parliament for the money to purchase the submarine cables. The splendid revenue derived by the present owners is proof that the traffic will bear the charges ; and to reduce them unduly would be simply throwing away the one good chance remaining of acquiring a profitable business to set off against the loss on the land lines.

THE lecture delivered by Dr. OLIVER LODGE before the Society of Arts, on Saturday afternoon last, marks a very distinct advance in our knowledge of the phenomena of the lightning flash. It would indeed be difficult to over estimate either the beauty or the intrinsic value of the series of experiments performed by the lecturer on this occasion. It has long been known that the static discharge is of an oscillatory character, but the full signification of this fact has never before been so fully disclosed. Some of the experimental results obtained are remarkable, not only in connection with the subject immediately under investigation, but also for the light shed upon other problems of importance which are at present engrossing the attention of electricians. One experiment, for instance, gives, we think, conclusive evidence—if more evidence be required—of the existence of true magnetic lag, while at the same time it throws a new and very surprising light upon the important question of the magnetic permeability of iron under extremely rapid reversals, of which so very little has hitherto been known. The result is absolutely to upset our preconceived ideas in a way that, as the lecturer himself remarked, could not possibly have been foreseen. We are, in fact, led to the astonishing conclusion 'that iron is more suitable than copper for lightning-conductors, because *for extremely rapid current reversals it possesses a smaller coefficient of self-induction.*

IT is worthy of note that in the experiments on lightning protectors for telegraphic purposes which were carried out by Profs. HUGHES and GUILLEMIN as long ago as 1864, evidence which clearly admits of a similar interpretation was obtained. The experiments were almost identical with those of Dr. LODGE: a Leyden jar battery was discharged through a fine iron wire, and a spark discharger (or "lightning protector") was placed across its terminals. The result was that for powerful discharges "the fine iron wire was invariably destroyed, even with the best form of lightning protector" that could be obtained. The experiment was then varied by removing the lightning protector and joining the conductor direct to earth "by a copper stranded wire of 1cm. diameter," *notwithstanding which "with powerful discharges the wire beyond the protector was invariably burnt."* When, however, the copper wire was replaced by a thin sheet of the same metal complete protection was afforded. (*See* Prof. HUGHES' Presidential Address before the Society of Telegraph-Engineers, January 29, 1886, reported in *The Electrician* of February 5 following, page 257.) Prof. AYRTON has also, we believe, obtained evidence tending to show that with very rapid alternations the magnetic permeability of iron tends to decrease, but the fact that this decrease eventually leaves the total impedance of an iron wire very considerably *smaller* than that of a copper wire of the same length *and about five times the sectional area* was absolutely unforeseen.

WE beg to be allowed sincerely to congratulate Dr. SILVANUS THOMPSON on having foreshadowed this result a few weeks ago. Dr. THOMPSON'S precognition is the more remarkable because, as will be remembered, he determined at all hazards to avoid any consideration whatever for that particular term which now turns out to be the most powerful supporter of his thesis. We should scarcely be surprised to find that the Doctor was quite as much astonished at this result as anybody else. Nevertheless, we are happy to recognise his undoubted claim to priority in the restitution of iron to what now appears to be its true position as the lightning conductor *par excellence.*

WE shall take the earliest possible opportunity of publishing these lectures *in extenso*, and need therefore say no more at present, save only to add the remark that all the experiments were carried out by the most simple means, and anyone who possesses a Holtz, or a Wimshurst, or a Voss machine, will be able to repeat them quite easily.

MR. SYMONS' paper on the non-existence of thunderbolts, "illustrated by specimens," which was read on Wednesday evening before the Royal Meteorological Society, will be found in another column. The paper was admirable in tone and in intention, and was heard with much appreciation. We have not illustrated the specimens ourselves, for reasons which will be apparent on a perusal of the paper.

Digitized by Google

It will be seen from Mr. Wilberforce's letter further on that the experiment recently suggested in these columns for obtaining a visible presentation of phase retardation has been tried at the Cavendish Laboratory, but without success. As Mr. Wilberforce points out, the inclusion of the Geissler tube makes the resistance of the circuit so great that at the rate of vibration of an ordinary make-and-break, the impedance is not much affected by shifting the core of the solenoid.

There can be no doubt that there is room for improvement and invention in the methods of covering wires for the purposes of modern electrical engineering. For submarine cable purposes the process has long ago attained perfection, but both for telephony and for electric light wires the requirements are of a different character, and it is impossible to suppose that finality has been obtained. Two novel and different processes are described in our columns this week, to which we would call the attention of those interested, without, however, expressing any opinion of our own on the merits of either.

We are quite able to sympathise with the wrath and indignation of an esteemed contemporary who last week published some information concerning a renewed attempt to float the Water Primary Battery Company, with a modest capital of £600,000. We are even prepared to take into serious consideration the proposal "to form an Association for the Abolition of Primary Batteries." But from the inquiries which we have instituted we gather that our contemporary has been misled. At any rate, M. Paul Raoul de Fancheux D'Humy has personally assured our representative that no such prospectus has been issued, and that he knows nothing whatever of any new proposal to form a company.

"The gas was extinguished shortly after the fire broke out." Such is the concluding item of intelligence which comes to us respecting the destruction of the Baquet Theatre at Oporto. That statement ought to stand first; for although the conflagration was the primary cause of disaster, the darkness was the ultimate cause of the fatalities attending it.

The Telegraph Offices of the World.—The *Journal Télégraphique* gives the total number of public telegraph offices in the whole world at 57,000.

Repair of the Suakin Cable.—The Eastern Telegraph Company announce that the Perim-Suakin Cable is repaired and communication with Suakin restored.

The Washington Capitol Struck by Lightning.—A Reuter's telegram states that the dome of the Capitol was struck on Wednesday last by lightning. The shock was severe, but no serious damage was done.

Dewsbury.—At a meeting of the Dewsbury Town Council, the Town Hall Committee agreed to communicate with electric lighting companies and contractors with a view of ascertaining the cost of lighting the Town Hall.

Proposed Cable from Spain to the Balearic Isles.—According to the Spanish journal *Industria e Invenciones*, the Government intend to lay a new cable from Spain to the Balearic Islands; the contract will probably be given to a foreign firm.

"Factory Accounts."—We are pleased to note that the excellent work on "Factory Accounts, their Principles and Practice," by Messrs. E. Garcke and J. M. Fells, has already reached a second edition. The publishers are Messrs. Crosby Lockwood and Son.

The Lighting of the Barcelona Exhibition.—The forthcoming exhibition at Barcelona is to be lighted by 400 arc lamps. The contract has been given to the Spanish Electrical Company, but it is understood that they will enlist the assistance of several foreign firms.

The Electric Light on the Great Northern Railway.—The lighting of the Edinburgh express by Mr. Radcliffe's device (in which the dynamo is driven from the axle in the guard's van) has proved so satisfactory that several local trains are now being fitted with the plant.

Bell versus Drawbaugh.—In the long pending action to test the validity of the Bell telephone patents in America, the Supreme Court of the United States has decided in favour of the Bell Telephone Company on every point, although a minority of three judges were in favour of the Drawbaugh claims.

Festivities.—On Thursday evening last, Messrs. R. E. Crompton and Co. gave a dinner at the Holborn Restaurant to their past and present pupils, to which also a number of their friends were invited. The after dinner proceedings were of an interesting character; the musical portion of the programme was contributed by Messrs. Spagnoletti, Gatehouse, Harrison and Alabaster.

The Effects of Residual Magnetisation on Bismuth.—From a note in the *Comptes Rendus*, we learn that M. P. Joubin finds that in the magnetic field bismuth presents an effect of hysteresis similar to that of soft iron—that is to say, when supported by a bifilar suspension in a magnetic field, the amount of its deflection for a given magnetising current at any time depends upon whether the current has been increased or diminished to its present value.

Electric Traction.—An electric railway, about six kilometres in length, is to be constructed in the Department of Haute-Savoie. The line will start from the Etrembières, and passing through Monnetier-Mornicx, will terminate on the plateau of the Grand-Salène, at a little place called Treize-Arbres. From this plateau there is a magnificent panoramic view of the Jura Alps. The line is intended almost solely for the convenience of tourists, the population being very sparse.

The Electro-Harmonic Society.—The last smoking concert of the season 1887-1888 will take place at the usual *rendezvous* on Friday evening, April 6th. An innovation in entertainments of the kind will be made, a string quartette rendering of works by Mozart and Haydn taking the place of the usual glee party. Violin duets, which some decades since were so fashionable, but which are now rarely heard, will also be played, and the vocal element will be ably sustained by Messrs. Arthur Thompson and Robert Hilton, and Master Humm.

Copper.—The most noteworthy event for some weeks in the copper market (says *Bradstreet's*) is the official announcement that the Calumet and Hecla Company has sold its entire production for three years to the French combination. No restriction is placed on its output, which is likely to be enormously increased within a year or two. The February product was at the rate of 35,000,000lb. of ingot copper per annum. The price secured is about 13 cents, while the cost does not exceed 7 cents. This makes a clear profit of $2,100,000 a year.

Telegraphic Mercantile Codes. — In another page will be found an advertisement of a series of Mercantile Codes which is of interest as having been compiled by telegraphic experts with special reference to the elimination of all words the telegraphic signals of which are liable in transmission to be mistaken for those of others words. In these days, when large firms spend thousands of pounds upon their Codes, it is important to have such a selection of words as will reduce the probability of errors to a minimum.

Royal Dublin Society.—The afternoon scientific lectures of this society are being given during the present week by the Rev. Gerald Molloy, D.D., on the subject of electric lighting. In the first lecture on Wednesday he dealt with the question how the electric current is produced, and explained the principle of the dynamo-electric machine. In the second lecture to-day (Friday) he will deal with the question how the electric current is made to generate light, giving some account of the action of electric lamps, their construction, and their history. The lectures are illustrated by experiments.

Edinburgh.—At a meeting of the Free Library Committee on Saturday Mr. Bryson, electrician, read the specification he had prepared for the electric light in the library. In this he made provision for 70 Swan or Edison incandescent lamps of 16 candle-power and 22 arc lamps of 1,000 candle-power each, the power to be provided by two engines of 30 horse-power each. He estimated the annual cost, including depreciation, at £400. 10s. 8d. After some further conversation, it was agreed to adopt the specifications lodged by Mr. Bryson, and to send the subject back to the same committee to take estimates.

Volunteer Submarine Miners.—The *Volunteer Record* says :—"The Volunteer Submarine Miners are to be styled 'Engineer Volunteers Submarine Miners, Royal Engineers,' whilst the Engineer Volunteers will be known as 'Engineer Volunteers Fortress and Railway Forces, Royal Engineers.' It may not be generally known that a committee has assembled, and already taken evidence upon the whole question of the formation, instruction, and drill of the force, and some important alterations in the regulations referring to them are not unlikely to be the result, and a large extension of the force is likely to be decided upon. It is probable that additional companies will be enrolled under the amended regulations."

Bishopsgate Ward Club and the Lighting of the City.—Mr. E. G. Cherry presided at the fortnightly meeting of the Bishopsgate Ward Club, at Crosby Hall, on Wednesday, there being a large attendance of members. On the motion of Mr. Watson Dyer, seconded by Dr. Holt, and after a lengthy discussion, in which Mr. Cherry, Mr. F. Dadswell, Mr. J. Collinson, Mr. M. H. Liverten, Mr. Roberts, and Mr. F. Nix took part, the following resolution was unanimously carried: "That, in the opinion of this club, the City of London should be lighted by the electric light, and this club further considers that no contract for that purpose should be entered into which does not give the ratepayers the power of compulsory purchase."

Refining Sugar by Electricity.—Some time ago a sensation was caused by the announcement that sugar could be refined by electricity. The Electric Sugar Refining Company in New York is now said to be getting its plant ready for manufacturing in Brooklyn, and it will use the process invented by Mr. Henry Friend. It is claimed that this system will convert a ton of raw sugar in two hours into perfectly hard white sugar at a cost of 3s. 2d. a ton, and that the company intends to turn out 3,000 barrels a day of crystallised sugar of various sizes. The capital stock is a million dollars, and there are 450 shareholders, including a number of those interested in the sugar business. The results in this case will be awaited with a good deal of interest.

Maturing Wines by Electricity.—M. Mengarini is continuing the investigations of Blaserna and Carpine upon the method of artificially maturing wines by the electric current. In his experiments a current of about four amperes (our authority, *Le Cosmos*, says 3·99 amperes *per hour*) was passed through the wine for periods of varying length. The electrodes, which are of platinum, become coated with a deposit which consists chiefly of albuminous substances. The proportion of alcohol was diminished by the formation of a small quantity of acetic acid, and also by evaporation. It is also probable that some of the alcohol was directly oxidised. The bouquet of the wine is developed almost exactly as if by lapse of time, and it was sensibly increased at every application of the current. The colour is also modified. There is also reason to believe that the wine is sterilised, so as to be incapable of further change; but on this point M. Mengarini is not able to speak positively at present.

Re-Determination of the Value of "v."—M. Himstedt has recently made a re-determination of the value of the ratio "v" between the electro-magnetic and the electrostatic units. He adopted the condenser method described by Maxwell in p. 776, Vol. II., of the "Treatise." In a series of fourteen experiments, very concordant results were obtained, the mean value arrived at being

$$v = 30{\cdot}074 \times 10^9 \text{ centimetres per second.}$$

This is slightly higher than the value hitherto assumed as most probable. From the mean of four determinations selected by Gordon as the most probably accurate $v = 29{\cdot}857 \times 10^9$ M. Himstedt has previously experimented by the condenser method of Ayrton and Perry, and obtained the value $v = 30{\cdot}14 \times 10^9$. The mean value obtained from ninety-eight experiments by Ayrton and Perry was $29{\cdot}8 \times 10^9$ (not $29{\cdot}4 \times 10^9$, as given by the author).

Exhibition of the Royal Meteorological Society.—The ninth annual exhibition of the Royal Meteorological Society was opened on Tuesday evening at the Institution of Civil Engineers, 25, Great George-street, Westminster. It is devoted chiefly to instruments connected with atmospheric electricity. There are various forms of electrometers, including those formerly in use at the Greenwich and Kew Observatories. Many patterns of lightning conductors are exhibited, together with models of churches, houses, chimney shafts, and ships, showing the various methods of protection. The Post Office shows a number of lightning protectors used for telegraph purposes. One of the special features of the exhibition is a collection of over 50 photographs of flashes of lightning. Many of these were taken during the great thunderstorm which occurred in London on August 17 last year There are also a large number of photographs of damage by lightning. The exhibition remains open till to-day (Friday). Next week we shall give an illustrated description of the most interesting exhibits.

Southampton.—The garbage and town refuse of Southampton is largely disposed of in a destructor. This means the generation of heat, which is turned to advantage in raising steam, and of which circumstance advantage was recently taken by the borough surveyor, Mr. W. B. G. Bennett, to carry out an interesting experiment in electric lighting. The dynamo used for the production of the electric light in connection with the Jubilee illuminations happened to remain in Southampton, and the borough surveyor obtained permission for its temporary use. At present the circuit supplies twelve glow lamps and four arc

Digitized by Google

lights, each of 3,000 candle-power. The maximum capacity of the dynamo is equal to ten of the 3,000 candle-power arc lights, or 250 glow lamps. The arcs are placed on the Corporation Wharf, while the incandescents light the office, the wheelwrights' shop, the engine house, and the destructor. Beyond the outlay for the dynamo, and the necessary arrangements, there is practically no expense for the production of the electric light except that involved in supervision and attendance. The cost is stated to be considerably under that of the present gas lighting.

M. Cailletet's Electric Furnace.—M. Cailletet, whose name is so intimately connected with the liquefaction of the "permanent" gases, has recently been studying the behaviour of gases under high temperature and high pressure. For this purpose he has made use of an "electric furnace," of which the following description is given in the *Comptes Rendus*:—"This apparatus consists of a mass of steel, in which is a cylindrical cavity one-fourth of a litre in capacity; a kind of stop-valve with a screw thread closes the opening. Two copper rods are attached to the cover, one of which is insulated from it. The platinum electrodes are attached to these rods, and vary in form according to the kind of experiment which is to be made. Usually a closed circuit is employed, and the copper rods are joined by a platinum wire spiral. The current is furnished by accumulators, and the gas to be examined is forced in at high pressure through a capillary hole bored in the solid steel. The platinum is then brought to a white heat and after a more or less prolonged period the gas is withdrawn for examination. By means of a small window filled with a special glass it is also possible to observe what goes on within the furnace. In this way by the substitution of carbon for the platinum electrodes, the behaviour of the electric arc at high pressures has been examined."

The Paris Exhibition.—A meeting was held at the Mansion House on Friday last under the presidency of the Lord Mayor for the purpose of forming some body of a responsible character to organise the British Section of the Paris Universal Exhibition of 1889. It was stated that in response to an urgent appeal from the Director-General of the Exhibition the Lord Mayor, with the tacit consent of the Government, had undertaken to form a committee for the purpose. An executive council had been appointed, and great care had been taken to include representatives, not only of various branches of industry, but also of the chief manufacturing centres of the country. The amount of space which would be placed at the disposal of Great Britain and the Colonies would be about 150,000 square feet. The most important question for the committee was that of finance, and it was necessary to have a guarantee fund.—Lord Brassey said they were met to arrange for the adequate representation of British industry at the Paris Exhibition. The Government would not be officially connected with the Exhibition, and it was necessary, therefore, they should make arrangements for themselves. He moved "That this meeting pledges itself to promote the interests of the Paris Exhibition, and to use its best endeavours to secure an adequate representation of British manufactures."—Sir B. Samuelson seconded the motion. The motion was unanimously adopted. A vote of thanks to the Lord Mayor for presiding closed the proceedings.

Overhead Wires.—On Thursday last a conference of the delegates appointed by the various metropolitan vestries and district boards of works was held at the Lambeth Vestry Hall, Kennington, Mr. F. H. Fowler in the chair. The following resolutions were unanimously agreed to: "That, in the opinion of this meeting of delegates from the various metropolitan vestries and district boards of works, it is desirable, in the interest of the inhabitants of the metropolis, that as a general principle all telephone, telegraph, and electric lighting wire within the metropolitan area should be placed underground." "That the control of the construction and maintenance of all telephone, telegraph, and electric lighting wires in the parishes mentioned in Schedules A and B to the Metropolis Local Management Act 1855, should, whether within 15ft. of the surface of the road or not, vest in, and be under the direction of, the vestry and district board of the parish or district in which such telephone and telegraph wires are situate." "That, in order to prevent any separate vestry or district board refusing arbitrarily the passage of through wire across their parish to the detriment of other parishes, an appeal should be allowed to the Metropolitan Board of Works similar to that sanctioned by Section 211 of the Metropolis Local Management Act, with reference to the orders or acts of the vestry or board in relation to buildings, sewers, &c." "That, considering the serious invasions, not only of public but also of private rights, proposed by the Bill of the United Telephone Company, the various vestries and district boards be recommended to adopt the foregoing resolutions, and to oppose the Bill with a view to having the principles embodied in such resolutions incorporated in the Bill, and such other amendments as are detailed in the petition of the Metropolitan Board of Works against the Bill."

Dr. Silvanus Thompson on Electric Bells.—A very clear and interesting lecture was given on "Electric Bells" by Prof. Silvanus Thompson, at the Royal Victoria Hall, on Tuesday. Instead of yielding to the temptation of travelling hurriedly over a large space of ground, he confined his attention to this small department of electrical science, and explained it thoroughly. A number of experiments were shown, illustrating both permanent and induced magnetism, and a variety of forms of electric bell were exhibited, from very sweet-toned church bells of a small size to a contrivance intended to wake up servants, which, when once the button is pushed, goes on ringing incessantly till the tormented servant goes to the bell and pulls a handle. Dr. Thompson then went on to inquire where the power comes from to produce these results, for we can never have results without a cause. There is no such thing as "perpetual motion;" wherever we have power, something must be spent to produce it. Here it is clear the power starts from the battery. What is used up there? In ordinary steam engines we burn coal; in a gun the fuel is gunpowder; in a battery it is zinc. Zinc is combustible in air, though not freely so, and in a battery it is burnt in acid, the combustion going on while the current passes and the bell rings, but at no other time. There are methods of obtaining a current without a battery—for instance, by turning a handle and causing a coil of wire to rotate in presence of a permanent magnet. But the same principle holds with all. Something is used up to obtain the power. In this case, the man who turns the handle plays the part of engine, and the food which he has eaten is consumed to do the work. In the course of the lecture, Dr. Thompson spoke of the large extent to which electric power is used in New England, as many as two hundred shops in one town being supplied with it from wires laid under the streets, as our gas-pipes are laid. But for vested interests, he said, the same thing might be done in London, and power supplied to workshops with much economy both of space and money.

The St. Petersburg Lighting Exhibition.—We take the following extract from an article in *Money*, a journal

Digitized by Google

which, however, is unmitigatedly hostile to the electric light:—"The 'Exhibition of Light,' or, as it is more commonly called, the Petroleum Exhibition, now being held at St. Petersburg, is of so instructive a character in regard to the progress of lighting of every kind, that it is a pity so few foreigners have paid it a visit. In practice is there demonstrated so clearly the opinions long maintained in *Money* respecting the ability of gas to hold its own against the electric light, that a few words about its display may interest its readers. The electric light has a section all to itself; the gas and the oil lamps are exhibited together. This has proved a bad arrangement in one respect, for when the hundreds of lamps and the hundreds of gas jets have been burning a couple of hours, the heat of the place is something infernal—often 100 degrees of heat F.—the temperature outside the Exhibition, into which the visitor plunges after quitting the building, being at the same time 20 degree below zero F.! However, Russians enjoy a contrast of this kind, and just now, when foreigners are not in favour, they have not the least objection to the Exhibition killing off as many as possible. The Exhibition is the creature of the Imperial Technical Society, and in general impartiality has been shown to every form of lighting. Kerosene or paraffin lamps are very well represented, and with respect to gas, there is hardly a new foreign patent which is not on view. The first impulse to modern electric lighting came, as is well known, from Russia, and since Jablochkoff made his first successful experiments in St. Petersburg, the Government and the municipal bodies of Russia, infinitely readier to accept new ideas and encourage inventors than the administration and local bodies of this country, have given it so much support that one would expect to find electric lighting very well represented, and in extensive use in Russia. The contrary, however, is the case. The Nevsky and two or three thoroughfares possess the light, and a few shops, hotels, and palaces are lit with it; but, generally, it is unpopular in Russia on account of its dearness—particularly in St. Petersburg—and, if anything, has rather retrograded than developed during the last twelvemonth. This retrogression is illustrated in the electric display at the Exhibition, which has a starved look about it, notwithstanding the favour shown it by the Imperial Technical Society. So unpopular is the light that it is a question whether the display has led to the slightest accession of business to the electric lighting firms. The case is very different with the display of gas and lamps. In both there are evidences of prosperity, of startling progress, and of improvements in cheapness and intensity of light that cannot but strike the most indifferent observer."

Proposed Electric Lighting for Torquay.——A meeting was held last week in St. George's Hall, Torquay, for the purpose of hearing an address from Mr. W. Radcliff, of London, on the advantages of electric lighting and the advisability of forming a limited liability company to promote this means of illumination at Torquay. Mr. Radcliff has successfully introduced the electric light on the stage of Torquay Theatre. The chair was taken by Mr. C. P. Henderson, and, although the attendance was not large, most of those present were tradesmen and showed much interest in the subject. It appeared, from Mr. Radcliff's remarks, that his proposal is only to introduce the electric light into houses and business premises, and not into the public streets, and to supply the area from Wood's Temperance Hotel at the top of Lower Union-street to the Queen's Hotel on the Strand. After giving facts and figures with a view of explaining the advantages of electricity, he pointed out that by carrying out the proposal to light houses only, they would avoid all the complications of the Electric Lighting Act, which, however, was being rapidly altered so as to meet the views of electricians generally. Dr. J. B. Richardson spoke of the injurious effects of gas on the system, and how it tended to produce consumption and other diseases, and he advocated electricity not only as a better illuminant than gas but because it would be the means of improving the health of the town. He had no doubt that, if the Gas Company could pay 10 per cent. dividend, an electric lighting company could be easily made to pay the same.—Mr. Radcliff said there would be no difficulty in raising the necessary capital in London, but by forming the company and supplying the electric light locally they would be getting it at cost price. He offered to put up the whole of the plant, and superintend its erection for a term of three years free of all professional charge whatever on condition that he received £50 a year for every 1 per cent. dividend which the company paid. He did not propose any particular system, but to use what was best in all of them.—Mr. O. S. Bartlett, solicitor, explained the legal formalities to be complied with in the event of its being decided to form a company. There were three methods—one by obtaining a license of the Board of Trade, the second by obtaining a provisional order, and the third by acquiring an Act of Parliament. He suggested that consideration should be confined to the first two methods. A license could only be obtained by first getting the consent of the local authority, and it expired at the end of fourteen years. Under a provisional order the company would be protected for forty years, at the end of which time the local authority would have power to purchase the plant and machinery. Under an order nothing could be done except at certain periods of the year, but with a license they could proceed at once. In either case a deposit of £50 would have to be made with the Board of Trade, and the expense of getting an order would be little more than that of obtaining a license. They should first get the order or license, and then form a company to raise the capital and carry out the works.—Mr. Radcliff, in reply to questions, said that the electric light could be sold at the rate of ½d. per hour for every 20-candle lamp, whilst the meters were absolutely accurate. (Laughter.) A capital of £12,000 would be sufficient for providing the plant for lighting the houses in the streets from Wood's Hotel to the Queen's. This was about one-half of what would be required from other companies, owing to the fact that they would have to pay no promotion money, and they would get their engineering done for nothing until they began to pay a dividend. He only proposed to light the main streets, and not the side streets. The wires could be laid along the copings of the houses.—Mr. Callard feared that there would be a difficulty in getting the consent of the Local Board to carrying wires overhead, whilst he questioned whether the proposed area was sufficient to ensure a remunerative dividend on the capital mentioned. He proposed that a committee be formed to go into the question of cost, and also the sightliness of the wires, before they took any initiatory steps for the formation of a company.—Mr. Radcliff replied that the wires could be laid in such a way as to be neither unsightly nor objectionable.—Mr. Edwards seconded Mr. Callard's proposition, and suggested an adjourned meeting. After further discussion, a resolution was carried, on the proposition of Dr. Richardson, "That in the opinion of this meeting it is desirable to form an electric light and power company, and that a committee be appointed to consider fully the necessary details and report to a future meeting." The committee was appointed, consisting of Dr. Richardson, and Messrs. Rockhey, Aitkin, Dendle, Edwards, Callard, Iredale, and Wood.

THE FRANKFURT-OFFENBACH ELECTRIC TRAMWAY.

BY E. KRAUSE.

This tramway has been constructed on the main road between Frankfurt and Offenbach on the Main, and has been in continuous working during the last four years. Tram rails have been used and put down as an ordinary tramway line; the rails are level with the road pavement. The general aspect of the line is shown in Fig. 1.

With reference to the map shown in Fig. 2, it will be seen that the electric tram line starts from the Charlemagne Bridge, in Frankfurt, and goes along the Sachsenhausen bank of the River Main; leaving the suburb behind, it passes through the village of Oberrad, which is situated about half-way of the whole line, and here has been erected the central station for the generation of the electric current. Leaving the village the tramway winds its way along the road and enters Offenbach at the west end, and traversing the town and market place it terminates at the Matilda-place. The whole length of the line is 4·14 miles. An extension of the electric tramway to the village of Buergen may in time be expected.

slotted at the bottom, as Fig. 3 in full size shows. The length of the tubes is 15ft., and they have been well bored out, and are therefore perfectly smooth and clean, so that the internal surface offers as little as possible mechanical or electrical resistance to the contact carriage sliding within. The tubes are screwed together by means of sockets in the usual way and then soldered. About 90ft. apart, but much closer in curves, wooden posts of the ordinary telegraph type are erected on one side of the road, on which cast-iron brackets, as shown in Fig. 4, are fastened. The brackets carry two iron-hooded insulators, on which the tubes are suspended by means of iron hooks. The posts are 18ft. high, and the tubes are arranged about 15ft. from the ground. To prevent the suspended tubes from sagging two stout iron-wire ropes have been stretched over insulators fastened on cast-iron brackets on the top of the posts all along the line, and the tube conductors are generally suspended twice between two posts, by means of clamps, to the ropes as shown in Fig. 5. The expansion of the conductors during hot weather will cause more sagging than in cold weather, when the conductors are almost straight; this, however, does not appear to give the least impediment to the moving contact carriage. The resistance of this tube conductor is only 1·6 ohm.

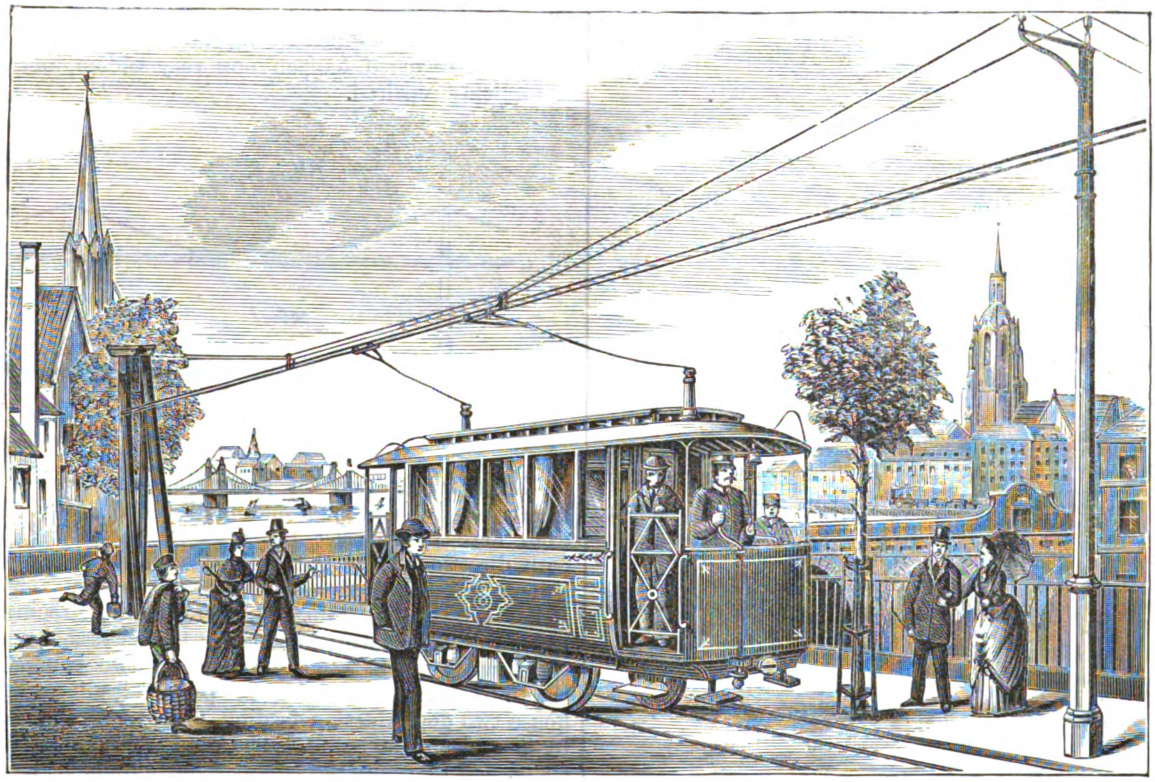

FIG. 1.
THE FRANKFURT-OFFENBACH ELECTRIC TRAMWAY—GENERAL VIEW.

The whole line is a single track line, but there have been arranged besides short double lines on both termini for shunting the carriages, and three passing places, distributed at nearly equal distances over the whole length, thus dividing the whole line into four sections. This makes it possible to increase the working capacity of the line and to have two trains going up and two trains going down the line at the same time. There have been at present fixed nineteen stopping places, as will be seen on the map. Many curves and gradients cause the working of this line to be difficult; the stiffest incline is 1 to 32 for almost 100 yards distance, another 1 to 45 for 150 yards, with a curve of 110ft. radius. The distance between the two rails is one metre.

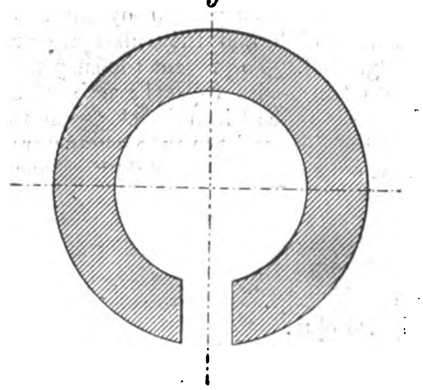
The conductors have been arranged overhead in a manner similar to that shown at the Electrical Exhibition in Paris, 1881, by Messrs. Siemens Brothers, and at the Electric Railway, Moedling, Vienna, where slotted wrought-iron tubes are used for conveying the electric current along the line. The tubes are of 1in. internal diameter and $1\frac{1}{8}$in. external diameter, and

As already mentioned, there are three passing places in the ground line, and this necessitated the arranging of three passing places in the overhead conductors for the contact carriages of the two passing tramcars. This problem has been solved in an ingenious manner, and is shown in Fig. 6. The two parallel running slotted tubes R and S are gradually bent, and where they would meet a part has been cut out and replaced by a well-seasoned piece of hard wood. The two tubes are partly let into it, and the bores and slots are cut through the wood. On the other end of the wooden piece H the tubes G and I continue the conductors. Thus the four tubes are insulated one from the other, and the contact carriage can slide from tube R to I, or from G to S—in other words, can go up or down the line as the arrows point. To connect, now, the positive leads S and G, and the negative conductors R and I, two metal pieces *m* and *n* are arranged above the wooden block H insulated from each other (*see* Fig. 7 in section), and screwed to the corresponding tubes. The different wooden pieces are then screwed

Digitized by Google

together with six bolts. To complete the passing place for the conductors the tubes L and K are joined to the tubes S and R, as shown in Fig. 6. When the contact carriage goes up or down the line it is necessary to direct it into the right tubes, which is effected by two movable tongues, *t* and *z*, pivoted at *p*, and shown in Fig. 8 in section. These tongues are always kept in the position shown in Fig. 6, which two

Fig. 3.



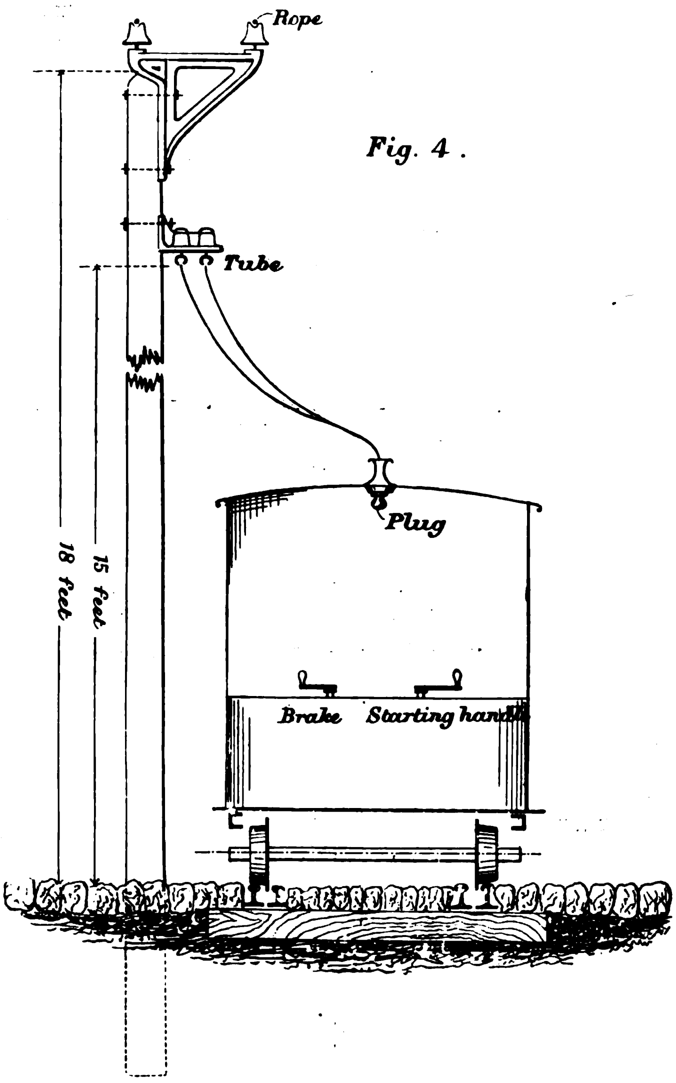


Fig. 4.

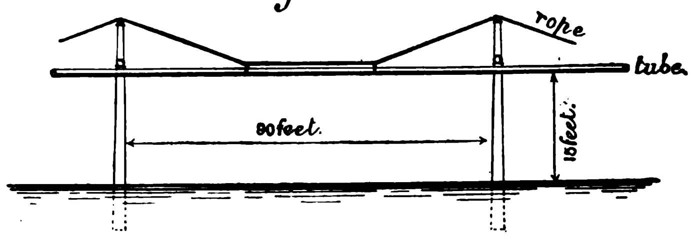
springs cause (*see* Fig. 9), acting on the upward bent end of the tongue. If a contact piece slides in R to the left, it will easily go into tube I—the tongue closes the way into K—and if a contact piston in G moves to the right, it will slide into tube S by pressing the tongue *t* aside.

This arrangement requires the contact carriage to be constructed in such a way that during passing through the wood heart piece H the flow of current to the tramcar is not interrupted, and also that it follows with perfect ease the curves of the conductors. Fig. 10 shows the tube conductor in longitudinal section and the contact carriage in elevation, Fig. 11 is a side elevation of it. Within the tube slide two cast-iron pistons C C, with pointed ends, and flat downwards projections, B, are cast on fitting into the slots of the tubes. These projections are riveted to a steel band, A, of ¾in. width and $\frac{1}{16}$in. thickness, which carries in the middle a bent brass piece, D, screwed to it. Besides the steel band connection two small copper wire ropes (not shown in Fig. 10) connect D to the right and left with the projections B and securing a safe passage for the current. The brass piece D contains also the insulated copper wire conductor E, which is fastened with slag to a rope, F, leading with the conductor E into the tramcar. On both ends of the steel band A are fastened two brass pieces carrying a steel rod, *d*, parallel to the tube conductor. Two metal pieces, *f*, screwed together slide on this rod, and carry between them a ring, to which the rope F is fastened. Rope F takes off the conducting wire rope E the strain caused by the moving of the tramcar. The two spiral springs on the rod *d* act as buffers when the pull is in one or the other direction. This arrangement, elastic in itself, has given great satisfaction during the four years' working of the line, and fractures of the rope F and copper wire E, which during the first few months' working frequently occurred, happen now very seldom, and are easily and quickly repaired.

Fig. 5.



The central station for generating the electric current has been erected about the middle of the line in Oberrad, and from here takes place the distribution of the current in both directions. In the boiler-house three large cylindrical boilers are provided with inclined fire-bars. The working steam pressure is 88lb. Under ordinary circumstances one boiler will be sufficient to generate the necessary steam, but at times, when much traffic takes place, two boilers are in use, the third is a spare one. In the passage leading to the engine-house two double-acting feeding pumps are put up, and close by is a deep water-well. The water contains a great deal of chalk, and therefore the boilers require frequent cleaning.

The engine house contains two separate large horizontal engines, both fitted with automatic expansion gear. The larger engine is a twin one, with modified Sulzer valve gear of 240 horse-power, but only one cylinder is at present used; the condensers which were for each cylinder provided have been removed on account of the scarcity of water. This engine has been built by Mr. R. Küchen, in Bielefeld, for the price of £1,400. The other engine, which has been lately erected, is a single-cylinder one of 120 horse-power, fitted with the well-known Collinann patent automatic valve gear, the cut-off being capable of being varied by the governor from *nil* to three-fourths of the stroke. Both engines are well suited for the heavy work, which consists of nearly eighteen hours' daily run, with only twenty minutes' stoppage during dinner time for lubricating purposes. Both automatic expansion gears have given great satisfaction, particularly when something wrong on the line happened. The diameter of the cylinder is 22in., by 37½in. stroke, and the speed is 75 revolutions per minute. The fly-wheel is 16ft. 6in. in diameter, and contains ten grooves for rope gear, but only six ropes 2in. in diameter are in use. Part of the exhaust steam is used for heating the feed water.

The countershaft is provided with couplings, and can be driven by both engines independently of each other; it has been arranged 20in. above the floor and makes about 300 revolutions.

There have been erected four vertical compound-wound Siemens dynamos, mounted on bed-plates with belt tightening gear, each capable of generating a current of seventy amperes and 300 volts = 21,000 watts, and absorbing about forty indicated horse-power each. There is room for four more dynamos. On week days, under ordinary circumstances, when only four tramcars are running, two dynamos will suffice to do the work, one engine working with one-half the power; but with eight electric trains on the road the engines indicated 164 horse-power. There is also provided a repairing shop, with a track of rails leading into it for repairing the electric cars. The offices are above the engine room. In case of fire there are fixed on different parts of the central station three hydrants, which are worked by a Korting injector; steam in the boilers is kept up day and night.

The rolling stock of this electric railway consists of 10 electric cars and four ordinary tramcars; the former weigh about four tons, carry 36 passengers, and cost £500 each; the latter weigh about two tons, and carry 24 passengers. The electric car (*see* Fig. 1) is much stronger in its frame, which consists of channel iron, and carries under the floor the electric motor. The armature makes about 500 revolutions per minute, and has a diameter of 15in., and is about 19in. long.

The method of gearing in this case consists of two pairs of spur wheels. The pinion on the motor-shaft is of gunmetal, and has a pitch-diameter of 6in. and 15 teeth by a width of $2\frac{1}{2}$in. In this gears a steel wheel of 22in. diameter with 55 teeth, mounted on a countershaft, which also carries a pinion of 12in. diameter and 26 teeth. This drives a wheel of 24in. diameter and 52 teeth, keyed on to the tramcar axle. The tramcar wheels are of 30in. diameter. The total ratio in the speed is therefore $\frac{55}{15} \times \frac{52}{26} = 7{\cdot}3$, and with 500 revolutions of the motor the speed of the electric car will be $\frac{500}{7{\cdot}3} \times 7{\cdot}85 = 537$ft. per minute, or 6·1 mile per hour.

The traction force on tramways amounts, according to Mr. Reckenzaun's tests, to 25lb. per ton rolling load on a level line, and the horse-power necessary to propel a train consisting of an electric car and an ordinary car, both with full load, with a speed of six miles an hour on a gradient of 1 to 32, will be found as follows:—

1 electric car, dead weight	4 tons
1 ordinary car, dead weight	2 ,,
26 and 24 passengers, each 1·5cwt....	4·5 ,,
Total	10·5 tons

$$\text{H.-P.} = \frac{W.K.S}{33000} + \frac{W \cdot 2240 S}{33000} \sin \theta^*$$

$$\text{H.-P.} = \frac{10{\cdot}5 \times 25 \times 537}{33000} + \frac{10{\cdot}5 \times 2240 \times 537}{33000} \times \frac{1}{32}$$

$$\text{H.-P.} = 4{\cdot}2 + 11{\cdot}9 = 16{\cdot}1.$$

If there are four such trains on the line, and the total efficiency taken to 40 per cent., the horse-power required to work the line would be $(16{\cdot}1 \times 4)\ 1{\cdot}6 = 103$ horse-power.

There were several difficulties to overcome besides following the road in all its curves and gradients. For the electric tramway crosses once an ordinary horse-tramway and several times the State railways, which are built on the same level as the main road. The rails of the former were cut and provided with chilled iron crossings as usual, but the latter were not allowed by the State railway authorities to be channelled for the passage of the wheels of the electric tramcars. It was therefore necessary to arrange on these rails wedge-shaped steel pieces, *a* (*see* Fig. 12), allowing the flange of the car-wheel to climb over the State rails as smoothly as possible. This, besides assisting the wheels to leave the metals, had the great drawback that the steel tyres of the wheels were worn in comparatively short time, and it was always necessary to drive very slowly over these railway tracks, or the inmates of the cars were subjected to not very pleasant joltings, as visitors will remember.

The wheels at first used were of a somewhat elastic construction, consisting of a spider keyed to the shaft, and the tooth-wheel formed a case with cover round it, the four projections of the spider pressed against india-rubber buffers inside the case, and thus gave a certain amount of dead motion to the gear, with the intent to smooth the starting. But now the cast steel rim of the wheel and the nave are connected by a disc of compressed paper (*see* Fig. 13), which design has given good results. On both ends of the tramcar are provided two handles, as fastened, one for the brake, which is arranged as on ordinary tramcars, and a loose handle for starting the motor and regulating its speed. If two electric cars are coupled together, forming one train, the starting gear on both are mechanically connected, and the driver in the first car has perfect control over both motors. The brakes on both cars are now also mechanically connected, and one driver works it as easily as possible. The cables for conveying the current enter the car through two tubes fastened on the roof of the car (*see* Fig. 4), and are brought under the floor to the brushes of the motor. Plugs are arranged in the roof above the driver's head, the drawing of which, in cases of emergency, interrupts the circuit, and consequently stops the motors.

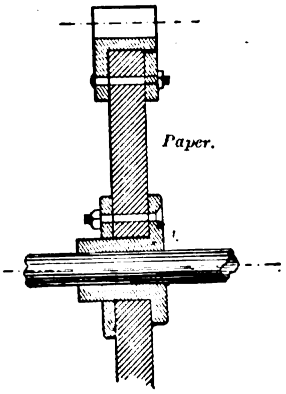

Fig. 13.

The Working.—The overhead conductors show scarcely any sign of wear, which may be due to the frequent cleaning and greasing of the tubes; the cast-iron pistons sliding in them last from five to six weeks, when they have to be renewed, the cost of which is very small. To the most wear and tear are exposed the wheels. The metal pinion wears out in about six weeks; wheels with helical teeth have given better results. Much more trouble has given heavy snow in the winter to this exposed line, and occasionally interrupted the traffic during a few hours. The trains run every twenty minutes from 6 a.m. till 11 p.m., and over one million passengers have been conveyed on this line during last year. On the whole the working of this line has been very satisfactory, and has given great credit to the makers, Siemens and Halske, who supplied the electrical plant.

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

(Continued from page 438.)

One of the chief difficulties which has been experienced by the telephone companies in extending their systems of exchange and private wires has been in obtaining way-leaves for their wires. The difficulty has chiefly arisen in the case of individual proprietors, and the local authorities have usually been ready to meet the companies in a reasonable spirit. In the case of the Wandsworth Board of Works, the United Telephone Company was refused permission to carry its wires across certain streets; but it was decided on appeal that the

* Vide *The Electrician*, January 6th, 1888, page 209.

Digitized by Google

Local Authority had no right to enforce such a prohibition, provided the wire did not interfere with the use of the street, was not a source of danger, and was not attached to supports placed in the street. The refusal, however, of some large London property owners to allow wires to be attached to their property has not only in many cases caused great expense to the companies by compelling them to carry their wires by circuitous routes, but in some instances it has shut out considerable districts from the advantages of telephonic communication.

In 1884 and 1885 Bills were promoted in Parliament by the United Telephone Company with the object of acquiring compulsory powers, where necessary, and of obtaining way-leaves, but they were both withdrawn, and need not be further noticed, as a Bill of similar character has been presented to the House of Commons during the present session, and we shall presently consider its more important provisions.

In March, 1885, a Select Committee of the House of Commons was appointed to consider the law relating to the control over telephone, telegraph, and other wires. A large number of witnesses were examined by the committee, including independent experts, the engineer of the United Telephone Company and other representatives of the companies, together with representatives of the vestries and of the "aggrieved householder."

The experts were almost unanimously of opinion that it was essential to the development of telephonic communication that overhead wires should be allowed, as the expense of carrying them all underground would make it necessary for the companies to charge prohibitive rents for the use of wires. It was also suggested that far more numerous and more serious accidents would probably occur during the process of breaking up the streets for the purpose of laying underground wires and for carrying out repairs, than the few trivial ones which had been caused by the breaking of the overhead wires.

As the result of the examination of the witnesses the committee drew up a report in May, in which they expressed the opinion that the risk of danger from overhead wires had been greatly exaggerated; but they stated that they considered there ought to be some change in the law relating to control over wires, with a view to their better supervision.

As the law then stood the Postmaster-General could lay wires, subject to certain notices and regulations, underground along country roads, without obtaining the consent of the road authority; but this had to be applied for in towns, with an ultimate appeal to the Railway Commissioners in case of refusal. For overhead wires, whether in town or country, permission had to be obtained, subject as before to appeal, and the permission was subject to various conditions, including a provision that a post must not be placed within ten yards of a dwelling house without the consent of the occupier. In the country there were various conditions with regard to permission of owners, with the right of appeal in case of refusal, and the publication of notices, which often involved considerable delay.

No power was given to the Postmaster-General to make attachments to private property without the consent of the owners, but in towns, with the permission of the road authority, he could carry wires over buildings, or lands other than building land or gardens, subject to certain restrictions.

The companies had no statutory powers, being merely licensees of the Postmaster-General, and they were therefore not able to carry wires over private property except with the consent of the owners. Certain corporations had also certain recently-conferred powers giving them authority to deal with wires.

Having regard to the state of the law the committee, having strongly expressed their opinion that no course should be adopted which would materially hamper the extension of the telephonic system, the free development and use of which they considered of essential importance to the public convenience, suggested that in order to obviate the difficulties and delays experienced by the Post Office in laying down wires, the Postmaster-General should be authorised to give notice of his intention of laying down a line of wire before instead of after obtaining the consent of the road authority, and that any objections should be referred to some competent tribunal.

The Postmaster-General they considered should also be allowed to make attachments to private property with the consent of the occupier only, without having, as heretofore, to obtain permission also from the lessee and the owner; but such consent on the part of an occupier should only hold good during the term of his occupation.

With regard to the telephone companies the committee considered that they should have the same power of running wires as was recommended for the Postmaster-General, provided that their wires did not interfere with those required for the public telegraphic service by the Postmaster-General. They should also be allowed under proper regulations to carry their wires over private property without the owners or occupiers having the right of prohibition, but they should be required to remove them for any good cause shown, and should be responsible for any damage caused by them.

With regard to attachment, the committee considered that when it could be shown to the satisfaction of the local authority that certain individuals or districts were debarred from the use of the telephone, as was the case with the Inner Temple and Covent Garden, on account of the refusal of way-leaves, compulsory powers should be given to the companies subject to the payment of reasonable compensation.

They proposed that bye-laws for the regulation of wires should be made for London by the Metropolitan Board of Works, for provincial towns by the Corporation, and for rural districts by the Local Authority, subject in each case to the sanction of the Board of Trade, and that in London the enforcement of the bye-laws should be entrusted to the City Corporation and to the Vestries and District Boards. Arrangements should be made for the identification of wires, by registration or otherwise, and all ownerless wires should be removed.

The United Telephone Company's Bill now before Parliament practically embodies these recommendations of the Committee with respect to the telephone companies. A clause is inserted enacting that wires shall not be carried over Crown lands or public buildings without permission from the proper authorities.

(To be continued.)

A CENTRAL ELECTRIC LIGHTING STATION AT AMSTERDAM.

(FROM A CORRESPONDENT IN HOLLAND.)

A central electric lighting station is in process of construction at Amsterdam. Some time ago a company was formed in this city, with a capital of 600,000 guilders, for the purpose of supplying electric light to the shops on the Kalverstraat and the Vorburgwal from a central station. After consultation with some thoroughly competent engineers, it has been decided to adopt an arrangement which has not hitherto been applied to central stations. On account of the relatively short distances the employment of alternate-current machines and transformers has been abandoned, and the work will be done by continuous-current machines. The combination of high-speed engines and small dynamos, as well as the use of resistance-regulators, for maintaining the tension constant, as is customary in all central stations in Germany (at Berlin, Lubeck, and Elberfeld), has been set aside as technically deficient. It has been decided to put up but two very large slow-speed dynamos with automatic potential regulation.

It is intended to use two compound condensing steam engines of 240 horse-power each, running at 100 revolutions per minute. Upon the axle of each engine the dynamo which is combined with the fly-wheel is mounted. The dynamo therefore also makes but 100 revolutions per minute, and feeds, when normally loaded, 2,400 incandescent lamps of sixteen candles. The machine will, however, be capable of taking a maximum load of 4,000 lamps. Accordingly the normal output of 250 horse-power as stated above is to be understood with the steam engine working under the most favourable steam supply. By increasing the supply the output can be raised to 400 horse-power.

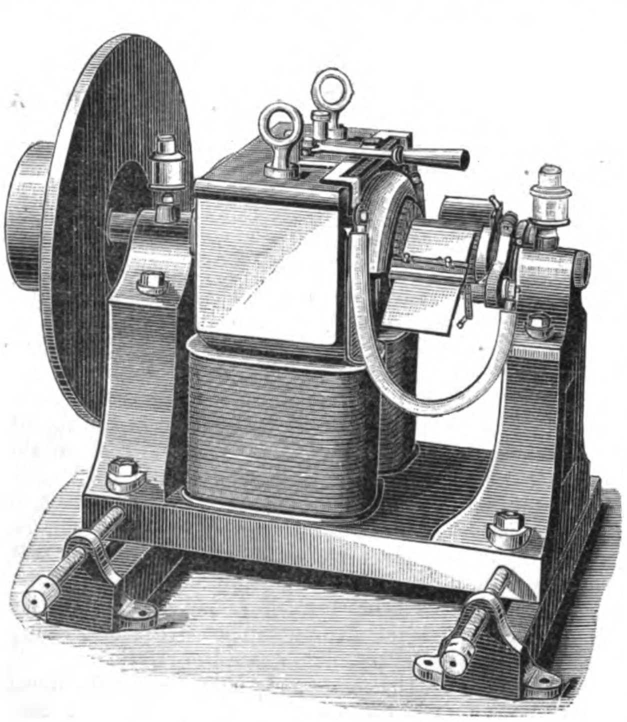
Both machines will work upon one line of conductors. The engaging and disengaging of each machine is done by simply moving a lever

Considering that with this arrangement all intermediate factors as belts, counter-shafting, &c., are done away with, and that the speed is only 100 revolutions, it appears that the security of working will surpass anything hitherto existing, the more so as the machines are but moderately loaded. But if necessity should arise either of the machines can at once be put out of gear, as each of them is capable of doing the whole work. Apart from the highly interesting general arrangement, it appears that the question of ample reserve has also been fully solved in this instance. The main conductors are so large that the maximum current will not involve a greater loss of tension than 5 volts.

The leading idea in planning this station has been not only to adopt the technically best arrangement, but also to simplify the working as much as possible, and to make it economically cheap. By avoiding the numerous small machines, by reducing the number of revolutions, by doing away with all regulators of resistance, it is hoped to be able to reduce the service to four or five men; whilst, for instance, the central stations put up at Berlin for the same output require not less than twenty men in the Markgrafenstrasse, and fifteen in the Manerstrasse. It would appear from this, as well as from the fact of the more economical working of slow-speed compound steam-engines, that a considerable higher rate of profit may reasonably be expected. The execution of the whole installation was entrusted to the Helios Company, at Ehrenfeld and Cologne, who alone have hitherto built large slow-speed dynamos for continuous currents. The machines were designed by Mr. H. Coerher, the manager of the Helios Company.

MESSRS. FOWLER, LANCASTER AND CO.'S DYNAMOS.

We illustrate herewith a dynamo of the Kapp type, constructed by Messrs. Fowler, Lancaster and Co., of Birmingham.



THE FOWLER-LANCASTER DYNAMO.

Our illustration is taken from a photograph of a 3-unit machine, intended to run at 1,000 revolutions per minute, and giving 63 volts with 53 amperes. The field-magnets and pole-pieces are forged in one piece of best Swedish iron, planed and shaped. The pole-pieces are polished and varnished. The commutator is phosphor bronze, and has 48 sections, with 4 turns of wire in one layer connected to each section. The armature is of the ring type, its core is built up of charcoal iron discs, No. 22 wire gauge thickness. The diameter is 8¼in., and resistance ·058 ohms, the resistance of the field being 18 ohms. The brushes are made of strip copper, the inside strips being slit, but not those outside. The machine runs quite cool, and without sparking at the brushes. Altogether the machine seems to be a very good specimen of modern dynamo practice.

ON THE CHANGES PRODUCED BY MAGNETISATION IN THE DIMENSIONS OF RINGS AND RODS OF IRON AND OF SOME OTHER METALS.*

BY SHELFORD BIDWELL, M.A., F.R.S.

In a paper communicated to the Royal Society in 1885,† the author has shown that the elongation which an iron rod undergoes when magnetised does not, as had been generally believed, remain unchanged at a maximum when the magnetising force exceeds that which is sufficient to produce so-called saturation. On the contrary, he finds that when the magnetising force is continually increased beyond this limit the elongation becomes gradually less and less until the rod, after first returning to its original length, ultimately becomes actually *shorter* than when in the unmagnetised condition.

The experiments described in that paper are, however, open to objection on the following grounds:—(1) The field due to the magnetising solenoid was not quite uniform; (2) the effect of the ends of the rods was uncertain, and might have played some material part in the production of the phenomena in question; (3) all the rods used in the experiments retained a certain amount of permanent magnetism; (4) the experiments might with advantage have been carried further. The paper now offered to the society contains an account of some new experiments which were designed to meet the above objections.

Objections (1) and (2) were met by using rings instead of rods of iron, observations being made of the changes which occurred in their diameters under the influence of various magnetising forces obtained by passing currents of electricity through coils of wire encircling the rings. To remove the third objection the rings were demagnetised before every observation, by a modification of the method described by Prof. Ewing in the *Phil. Trans.*, Vol. CLXXVI., p. 537. And lastly, the battery employed was increased from seven Grove cells to thirty.

After an explanation of the precautions taken to guard against the effect of current heating, an account is given of some experiments with three rings arranged in slightly different ways, and the results are compared with those of an experiment made under similar conditions with a straight rod. It was found that in their general character the phenomena of elongation and retraction were just the same in both cases, and were in close agreement with those of the former paper. The differences in mere details were not greater than would probably be found to occur in different specimens of iron of the same form.

Being satisfied that these curious effects of magnetism were practically independent of the form of the iron, and having regard to the fact that it is much easier to obtain intense fields with straight than with circular solenoids, the author thought it worth while to make some further experiments with straight rods. The metals used in addition to iron were cobalt, nickel, manganese steel, and bismuth; and the highest magnetising force reached about 840 C.G.S. units, the maximum in the old experiments having been 290.

It was found that the retraction of the iron continued to increase with higher forces until it was finally as much as 45 ten-millionths of the length of the rod, when there were indications that a limit was being approached. The attraction of the nickel reached 113 ten-millionths, when it also was evidently not far from its limit.

The behaviour of the cobalt rod was exceedingly curious

* Abstract of paper presented to the Royal Society, Feb. 9, 1888.
† "Roy. Soc. Proc.," Vol. XL., 1886 (No. 242, p. 109).

Digitized by Google

and interesting. No evidence of any change of length appeared until the magnetising force exceeded 30 or 40 units. Then the length of the rod began to diminish, and continued diminishing until the force was about 400, when the retraction amounted to 50 ten-millionths. But beyond this point the rod gradually became longer again, and the retraction with the highest force of 800 units was only three fifths of its maximum amount. It was ascertained that the maximum retraction did not coincide with a maximum of magnetisation, as might have been suspected to be the case. It is suggested that iron and nickel might possibly behave in a similar manner under sufficiently high magnetising forces.*

Tables and curves are given showing the relation between magnetising force and changes of length in each metal.

Bismuth was found to be slightly elongated in strong fields, though no change could be detected with forces of less than about 500. The greatest elongation observed was about 1·5 ten-millionths of length. Manganese steel was almost unaffected. The elongation in a field of 850 was estimated to be about one fifty-millionth of the length.

Finally, it is shown that the mechanical stress produced in iron by magnetism does not account for more than one-fifth part of the observed magnetic retraction.

An appendix to the paper contains evidence of the high degree of accuracy obtainable by the method of observation employed. In the very great majority of the measurements of elongation and retraction, the probable error was less than one two and a-half millionth part of an inch, or one hundred-thousandth of a millimetre; and the results of experiments made upon different days (the apparatus having been in the meantime dismantled), or with currents of ascending and of descending strength, were strikingly concordant. This degree of precision is attributed to the perfection of the optical arrangements, which rendered it possible to project the image of a wire with such sharpness that after reflection from a mirror its position upan a scale 24ft. (732cm.) distant could be read to a quarter of a scale division, each whole division being equal to $\frac{1}{40}$in. (0·64 mm.). The magnifying power was such that a change of one two and a-half millionth part of an inch (or one hundred-thousandth of a millimetre) in the length of the rod under examination caused the image of the wire to move through about three-quarters of a scale division. More accurately, a scale division corresponds to 0·000018 mm.

The currents used were measured by one of Ayrton and Perry's commutator ammeters, and the accuracy with which the magnetising forces were estimated, though quite sufficient for the purpose of the experiments, does not claim to be very high.

COVERED WIRES: A NEW PROCESS OF INSULATION.

We learn from the *Centr. Blatt. für Elektr.* that MM. Weber and Schefbauer have succeeded in preparing insulated conductors by a new process, for which important advantages are claimed. The method is said to be particularly applicable to the manufacture of double or multiple wire cables of flat section, and it effectually prevents any change of relative position in the wires. Each wire is first wrapped in several layers of *paper*; it is then passed through a bath of ammoniacal oxide of copper, by which the superficial layers of the paper are converted into cellulose. In this stage the wires of the cable are laid together in position, and are then passed through a rolling mill; the cellulose layers are thus pressed into cohesion, and the whole forms one solid mass. By a mechanical device the wires are retained exactly in their true positions while passing under the rollers. The cable now again enters a bath (which performs some function not fully made known), and it is afterwards rolled a second time between hot rollers. The rollers are heated by steam, and apply a very powerful pressure. The object of the second rolling is chiefly to get rid of moisture. The cable is next passed into a bath of linseed oil at a boiling temperature, which thoroughly saturates the covering. Lastly, it passes once more through hot rollers to get rid of the excess of oil. The finished cable is very supple, and is proof against damage from moisture or from ordinary variations of temperature. Its durable qualities remain to be discovered.

* It is also suggested that some specimens of cobalt and nickel might, like iron, begin with a small preliminary elongation, thus accounting for Prof. Barrett's observation that cobalt undergoes elongation when magnetised (*Nature*, Vol. XXVI., p. 585).

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.*
It has the largest circulation of any English Electrical paper, and circulates all over the World.
Particulars relating to Advertisements will be promptly forwarded on application to this office.
Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

THE ELECTRICIANS' DIRECTORY.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

NOW READY.

Volume XIX. of "The Electrician," strongly bound in cloth, is NOW READY, price Ten Shillings and Sixpence.

Cases for binding "The Electrician," price Two Shillings, Now Ready.

GOOD FRIDAY NOTICE.

Next Week "THE ELECTRICIAN" will be published on THURSDAY morning. Advertisements should reach the Publisher not later than 4 o'clock on WEDNESDAY.

ANSWER TO CORRESPONDENT.

IGNORAMUS (London).—*It would certainly be possible to measure resistance with more or less approximate accuracy in the way which you propose. But, as you say, the tests would have to be made with a current of constant strength; and, if you consider further, you will probably see that the means by which you hope to secure this will be upset by the insertion of the wire as a shunt. The principal objection, would, however, arise from the fact that it is a non zero method. You are probably aware that far greater accuracy is attainable by balancing a galvanometer needle at zero than by taking deflection reading. In this respect the use of a Wheatstone bridge, or even of a differential galvanometer, is very much better than any such method as you propose.*

OUR ELECTRICAL DEFENCES.

The Report of the Committee on the Fortification of our Ports has drawn attention afresh to the unsatisfactory condition of these defences and to the measures necessary for their improvement. As regards the latter, Mr. STANHOPE'S statement in the House of Commons on the Naval and Military Estimates for the year encouraged the hope that something would be done at once for the existing forts, and something possibly in the future for the mercantile ports. The further protection of the naval dockyards and shipping lying behind such forts as Portsmouth and Plymouth being an admitted necessity will no doubt be taken in hand without delay; but we cannot feel the same assurance in respect to the merchant shipping ports, which at present are practically defenceless, and which are to be left to the joint action of the local authorities and the Government. The cheers which greeted the Secretary's announcement that he wanted to induce the localities "to come forward and co-operate with the Government for their own defence" were perhaps not of good omen for the suggestion, betraying, it may be feared, more satisfaction with its economy than anxiety for its success. Volunteer defence is no new thing in the history of this country; but the initiative has hitherto been taken under strong public impulse, and if the mercantile shipping ports have not yet proffered to defend or pay part of the cost of defending them it is probably because they are regarded as a national concern, and not merely as a local one. Nevertheless, some attempts have been made for the establishment of volunteer submarine mining corps, and it may be hoped that the

Digitized by Google

Government will approach these bodies with liberal terms, while, on the other hand, the local authorities should respond with that public spirit which has always characterised the voluntary effort where national safety is in question. Mr. STANHOPE tells us that no time should be lost: and without being alarmists we may take it that he has reasons for making an urgent appeal to the patriotism of the nation.

This being the case, the present seems an opportune occasion for dwelling on the part which electricity will play in these defensive measures. In one branch alone, that of submarine mining and torpedo operations, some articles recently published in these pages sufficiently indicate the importance of these implements of warfare and the ingenuity bestowed on their construction. There is a wide field still open for inventiveness in these appliances; and no nation stands so much in need of them as ourselves. As to the efficiency of submarine defences, even at their best there is a wide diversity of opinion, the late HOBART Pasha, for example, contemptuously thrusting aside all the torpedoes an enemy could bring against him. But Admiral HOBART was an Englishman, and whatever may be said against it we observe that foreign nations do not despise the torpedo, and count upon it largely for their own defence. Lieut.-Colonel BUCKNILL writing on this subject in our contemporary *Engineering* last July showed that during the American war of secession between December, 1862, and June, 1865, enormous damage was inflicted on the Federal navy and transport ships by Confederate submarine mines, although for a considerable time the Confederates possessed no special stores, no trained *personnel*, and but little scientific knowledge of the subject. As many as thirty-seven successful operations of this kind are recorded, the result of which was the destruction, partial or complete, of a like number of armour clads, monitors, gunboats, torpedo boats, or transports. Since the American war vast improvements have been made in these engines of destruction, most of which, we need hardly say, now depend more or less on electricity for their effective manipulation or automatic mechanism. The importance of this fact, it is gratifying to notice, has not been entirely overlooked by the naval authorities, whose school on H.M.S. "Vernon" is actively training specially selected men in those branches of scientific knowledge on which the success of torpedo and submarine mining warfare so closely depends. A similar school for the Royal Engineers has long been in operation at Chatham with such well-known advantage to the land forces that we need not further refer to it here.

The extension and organisation of Submarine Mine Volunteer Corps at all the important seaport towns of the kingdom will tax the resources of these schools to the utmost. The local volunteers cannot be expected to come to Chatham or to Portsmouth to be instructed in the use of the weapons placed at their disposal, and it follows that instructors will have to be—or ought to be—told off to the distant places to impart the necessary knowledge. It is no doubt the boast of every invention connected with mining warfare that non-skilled persons can be safely trusted to operate it. But if we took the inventor at his word there would be no need for naval or military mining schools; and we dwell on the importance of special training in this relation because, in view of the possible, and we hope probable, requirements of the mercantile ports, the supply of competent instructors may, we fear, fall short of the demand. From the navy, at all events, there is reason to apprehend that the amount of training has not exceeded, if, indeed, it has satisfied, the immediate needs of the service; and it is by no means certain that the Royal Engineering Corps could undertake the duties we are now discussing, which pertain more to the navy than to the army. Some unusual efforts have latterly been directed in both branches of the service to the diffusion of electrical knowledge. We hope and trust that account will be taken of the increasing demand for it by the auxiliary forces, who will naturally expect to get what they require through the instrumentality of the Admiralty or the War Office. Commenting on the condition of affairs disclosed by the Committee's report the *Standard* pronounces it both disgraceful and incredible that the wealthiest nation in the world is in such a defenceless plight because in time of peace it is too careless or too niggardly to provide what is wanted. These grave charges are, indeed, well deserved if the authorities decline to increase the number of naval and military technical schools, or, at least, to enlarge the capacities of the existing establishments.

We write on these points, however, not in confident expectation of being listened to. There are other matters which have long been discussed and recommended in connection with our coast defences, but which have received no attention. A recent issue of the *Liverpool Journal of Commerce* has revived a subject which long ago was warmly advocated in these pages—namely, the connection of our coastguard stations by electric telegraph. As a matter of fact, these stations are as isolated and as out of touch with the defensive forces of the land as if there were no land to defend, but only a Custom House office. The inconvenience of this isolation is felt by our shipping every day; but its danger in time of war was proved during the Jubilee Naval manœuvres, when the coastguard outlooks were impotent to render any service, because they had no telegraphic connection with the adjacent land lines. In one or two instances a connection was established, but with the aid of the Royal Engineers specially lent for the occasion. This incident, although creditable to the soldiers concerned, illustrates the helplessness to which our sailors are reduced by their enforced ignorance of telegraphy. Many exaggerated things are said about the unpreparedness of our navy, but we are guilty of no exaggeration when we say that at the present moment our first line of defence is utterly destitute of any knowledge, theoretical or practical, of electric telegraphy. Royal Engineers cannot always be had to order, and there is we believe no vessel in the navy that could land a party of men on this or any other coast capable of erecting a temporary telegraph wire, or of working it if erected for them. Excellent signalmen the navy possesses, and the Morse code is largely employed by them; it only needs to be applied to the manipulation of the Morse telegraph instrument to become available on emergencies such as have occurred already, and may occur again at any moment. The operations of submarine and military mining are closely associated with those of electric telegraphy; the laws which govern the one are applicable to the other, and it seems to us that in the navy it should be the rule, as happily it is in the army, to combine both subjects in the same course of instruction. To some extent these observations apply also to the auxiliary forces at mercantile ports, in the training of whom the value of electric telegraphy should not be overlooked.

Mr. W. S. Gilbert on the Electric Light for Theatres.— Replying to a representative of the *Pall Mall Gazette*, Mr. Gilbert is reported to have said:—

"If I were asked for my opinion, I should strongly recommend that the adoption of the electric light in theatres should be made compulsory by Act of Parliament. It always seems ridiculous to me that while the outcry about exits is chronic, no one thinks of striking at the root of the evil, which is the use of gas behind the stage, where all the materials are of the most inflammable nature. Very little danger can come of using gas in the auditorium, whereas, on the stage, it is a never-ending source of danger."

A PROPOSED NEW PUBLIC TELEPHONE SYSTEM FOR CITIES AND LARGE TOWNS.

BY WALKER MOSELEY.

(Continued from page 373.)

The method described for leading and joining up the metal tubed wires does not necessarily call for any change in either the method or the material employed for their insulation and sheathing, as the ordinary lead-covered wires would answer almost perfectly; but if the main objects can be attained by less bulky and less expansive coverings, the practical adoption of the plan I have so far described will be greatly facilitated. The lead-covered insulated wires at present in use are almost invariably insulated with gutta percha, for india-rubber, yielding more easily to pressure, would allow the central wire to be pressed out of the centre in some places, and thus spoil the average value of the insulation. A review of the considerations which have placed gutta percha and india-rubber in the highest rank as insulating materials for wire will show that an outside covering of metal entirely alters the relative merits of the insulating materials. Gutta percha is best under water or underground if constantly damp, but in places exposed to alternations of dry air and dampness, pure india-rubber is superior to all other insulators. Other materials, however good in their insulating qualities when fresh, become porous or rotten in two or three years if exposed to dry air. As for the most modern nostrum, "Kerite" or paraffin wax, it is untrustworthy whether new or old, for reasons well known to practical men. But if good permanent insulation is determined upon, it is now by common consent agreed that lead-covered wire ensures permanent insulation, and that for important purposes the extra cost is hardly worth consideration. But once arrived at that conclusion it naturally follows that if the metal sheathing protects the enclosed material from the action of dry air, it may be found that some of the less homogeneous or tenacious materials will prove very economical substitutes. Three necessary qualities must be combined before such a substitute can be safely adopted, viz.: 1st. Insulating properties equal to india-rubber or gutta percha. 2nd. Sufficient rigidity of substance when surrounding the wire to prevent the wire getting out of centre when being covered with the metal sheathing, and also to prevent creasing when the metal-covered wire is bent. 3rd. Sufficient elasticity to prevent crumbling under the act of such bending. I am not aware of any material that fulfils these conditions so well as hair, such as commonly passes under the name of horsehair.

Horsehair yarn tightly wound round the wire, and steeped in melted resin tempered with a small amount of boiled oil, furnishes a better insulation than either india-rubber or gutta percha, and for permanence it is well known that the materials, either separately or in combination, are practically imperishable under exposure to all weathers. I would not say such insulation would in all cases be trustworthy after rough handling and bending, but with the protection of a metal sheathing it would clearly withstand all the evil elements to which insulated wires are exposed. No insulated wires will stand rough handling without injury, and if metal-sheathed wires show the effects of rough handling more plainly than those without, there is so much better guarantee—under proper oversight—that the fixing of the wires is done with due care. The adoption of resined horsehair insulation opens up a further question, viz., whether lead covering cannot be improved upon? The usual process of lead covering is by passing the insulated wire through a large tube, and the latter is diminished as it passes through small dies until the last one closes the tube tight on the gutta-percha covering. To effect this by the direct process would cause the melted metal to soften the gutta percha and thereby allow the wire to run out of the centre, which would, in consequence, lessen the value of the insulation. The use of horsehair involves no risk of this kind, as the molten metal does not alter the hair, either to lessen its strength or elasticity. But the demand for a complete metallic circuit, for most purposes except public telegraphy, has at length become pronounced, and the question arises, why not use the outside metal covering for the return? The answer is, the covering must be reduced in weight and bulk or it would be impracticable to insulate it well enough to make it other than a mere earth return. The metal must also be a better conductor than tin or lead, as well as stronger. A copper sheathing supplies these desiderata, and it is effected as follows: Three thin, narrow copper tapes are drawn lengthwise outside the insulated wire, and three others outside the former, but overlapping the junctions of the inner tapes, as shown in sketch Fig. 5 (enlarged). These tapes all pass through guides and rubbers, and through a heated conical die, supplied with molten metal. As it passes out of this it is chilled by a trickling stream of water, and skimmed as it passes through a

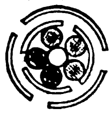

FIG 5

FIG 6

tubular dresser, and shows in section as a clean thin tube as shown, natural size for telephone, incandescent lighting, &c., at Fig. 6.

REVIEWS.

Electrical Instrument Making for Amateurs. By S. R. Bottone, Certificated Science Teacher, South Kensington. (Whittaker and Co.)

This is a book by an amateur for amateurs, and though not perfect, should do a considerable amount of good, especially if read in conjunction with some sound elementary text-book.

As long as the author confines himself to plain mechanical instruction how to put together rough but working apparatus, we can fully appreciate the value of his instructions. Let no one despise home-made work who has seen what Prof. Hughes can do with a few bits of iron, straw, and string; and an instrument, however rough, which a boy makes for himself, will teach him far more practical science than the very best he can buy in the shops.

The first half of the book is devoted to static electricity, and reminds us of a certain "Boys' Own Book" which we used to devour in our infancy. It is, however, fairly practical and good all through.

In the second half, dealing with electro-dynamic work, the author occasionally gets far astray. His directions for making and calibrating a voltmeter are fairly good, but we rather pity the amateur who tries to get the 1 ampere point on his ammeter by Mr. Bottone's method, viz., by trial and error to obtain a deposit on the cathode in a voltameter of exactly 18·35 grains of copper in one hour; there are sundry other minor beauties in the method which will be found at p. 120.

In the preface we are told that "nearly all the really useful inventions and discoveries of the nineteenth century must be attributed to amateurs." The following receipt is doubtless one of the discoveries alluded to, and for simplicity and clearness quite puts Mr. Kapp's professional paper of last year in the shade:—

"*To make an armature to give* A *amperes and* V *volts.*—Take V yards of wire $\frac{A}{1000}$ inch section, and make the armature just large enough to hold it. N.B.—For machines under 2cwt. allow more than V yards of wire." (Pp. 111-12.) Mr. Bottone is also seriously in error when he says that the magnetising force of an ampere-turn varies inversely as the square of its distance from the iron core. This is a mistake often made by amateurs, who find it difficult to realise the fact that the magnetising force of a layer of wire surrounding an iron arc and carrying a given current is *totally independent* of the radius of the coil.

On the whole it is really a great pity that Mr. Bottone did not get an electrician to look through his proofs, as it would have saved him making these and sundry other errors in an otherwise very useful book.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

Chapter VIII.—*The Calibration of Current Indicators.*

(Continued from page 506.)

93. *Use of the "Shunt."*—The sensitiveness of an indicator can be reduced by "shunting" it—that is, by connecting a resistance to its terminals; part of the current then flows through this resistance or is "shunted" past the instrument. A box containing resistance coils in which the resistance may be adjusted to any value by means of plugs, as before described, is connected to the terminals of the most sensitive indicator. This resistance so connected is technically known as a "shunt" on the instrument, and its duty is to conduct away a portion of the current, so that only a certain part of the current, say $\frac{1}{n}$th, flows through the instrument. If, then, we observe the current flowing through the instrument so shunted, we know that the current in the main circuit is n times as much. The value of the number "n" is then what is termed the "*multiplying power*" of the shunt.

94. *Practical Case of the Application of Shunts.*—A practical instance will best serve to make the action of the shunt clear. In Fig. 54, A B and C represent three indicators of different degrees of sensitiveness, which were calibrated at the same time. A few preliminary observations were taken, employing one secondary cell of negligible resistance and of 2 volts E.M.F. This was circuited in series with an adjustable resistance box, and the three instruments as shown. All three instruments had their needles suspended horizontally by silk fibres, but the instruments were very different in other respects. A was an astatic instrument, similar to that shown in Fig. 49, and wound to 544 ohms, B was a Walmesley-Mather instrument wound to 192 ohms, and C had a small needle surrounded by a large circular coil, constituting ordinarily a tangent galvanometer, but employed in this case with its coils moved out of the magnetic meridian by 60 degrees. This instrument was wound to 253 ohms, and the divided scale over which the needle could be deflected was marked out into 200 divisions. Before any instrument was shunted, it was found that with one cell in circuit A was deflected 80 degrees, B 52 degrees, and C 74 degrees, 11 ohms being unplugged in the resistance box, which, added to the total resistance of the instruments, made up the entire resistance of the circuit to an even 1,000 ohms. The deflection on C, which should be nearly 200 divisions, was too small, this instrument being the least sensitive, and therefore another cell was added to increase its deflection. Now, this increase in current increased the deflections on A and B also, and therefore shunts were put on them; but as it would never be possible to to obtain a deflection as great as 90 degrees on these two instruments (their coils being parallel to the magnetic meridian) it may be asked, why should they be shunted at all? The reason is that if the needle of an instrument is deflected very near 90 degrees it requires the addition of very large resistances in the circuit to reduce this deflection down to a very small angle. For the purpose of calibration it is sufficient to deflect up to 70 or 80 degrees, and, therefore, the deflections on A and B were reduced to about 75 degrees by the addition of shunts of such values that only $\frac{1}{5}$ of the current passed through A and $\frac{3}{4}$ through B—that is, the multiplying powers of these shunts were 5 and $\frac{4}{3}$ respectively. There were then conveniently large deflections on each instrument, viz., 74½ degrees on A, 74 degrees on B, and 187 divisions on C. This was with 94 ohms unplugged in the resistance box, which, together with the resistance of the instruments (A with shunt = 109 ohms, B with shunt = 144 ohms, and C unshunted = 253 ohms) made up an even 600 ohms; the main current was therefore $\frac{4 \text{ volts}}{600 \text{ ohms}}$ in amperes, or 6·6 milliamperes.

95. *Calculations to be Made when Shunts are Employed.*—From the above practical case of the use of shunts it will be noticed that there are one or two little calculations to be made when they are employed, viz.:—

(1.) What is the ratio between the current in the main circuit and that passing through the instrument, shunted with a given resistance, or, in other words, what is the multiplying power of a given shunt?

If we call this ratio "n," it is clear that $\frac{1}{n}$th of the main current passes through the instrument, and therefore we must multiply the current passing through the instrument by n to find the value of the main current. Hence, the ratio n of the two currents is known as the "multiplying power" of the shunt.

In Fig. 55 an instrument is shown with a shunt attached to its terminals 1, 2; the main current arriving at terminal 2 divides between the two paths open to it, these two currents recombining again at terminal 1 and passing on. There must be a certain difference of potential between the terminals 1 and 2, or there would be no current, and this difference of potential is the same for both instrument and shunt, since both are joined directly to the terminals 1 and 2. Therefore, by Ohm's law (para 50) the currents through these two paths are proportional to their respective conductivities, and the sum of the two currents, *i.e.*, the main current, is also proportional to the combined conductivity of the two paths. From this consideration we have at once the relation between the main

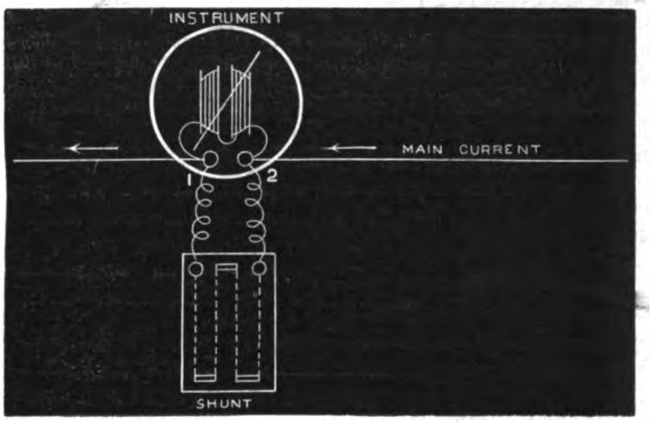

Fig. 55.

current and the current through the instrument expressed in the following proportion:—

main current : current through instrument :: combined conductivity : conductivity of instrument.

Representing, as above, by the letter n, the ratio between the two currents in the first and second terms of this proportion, we have

$$n = \frac{\text{combined conductivity}}{\text{conductivity of instrument}}.$$

It is, however, more convenient for practical use to express n in terms of resistances instead of conductivities, and we know that the conductivity of the instrument is

$$\frac{1}{\text{instrument resistance}},$$

and the combined conductivity of instrument and shunt is

$$\frac{1}{\text{instrument resistance}} + \frac{1}{\text{shunt resistance}};$$

whence we get

$$n = \frac{\dfrac{1}{\text{instrument resistance}} + \dfrac{1}{\text{shunt resistance}}}{\dfrac{1}{\text{instrument resistance}}},$$

Digitized by Google

Dividing it out we have

$$n = 1 + \frac{\text{instrument resistance}}{\text{shunt resistance}},$$

which is the usual expression for calculating the multiplying power of a shunt. Expressed in words, *the multiplying power of a shunt is found by dividing the instrument resistance by the shunt resistance, and adding unity to the quotient.*

(2.) When a given multiplying power, n, is required, what must be the resistance of the shunt? This is at once derived from the last result, from which we obtain

$$n - 1 = \frac{\text{instrument resistance}}{\text{shunt resistance}},$$

and therefore

$$\text{shunt resistance} = \frac{\text{instrument resistance}}{n - 1}.$$

Applying this to the practical examples of the shunted instruments in para. 94, instrument A (of 544 ohms) was shunted with a shunt of multiplying power 5, and therefore the resistance of this shunt was

$$\frac{544}{5 - 1} = 136 \text{ ohms}.$$

Instrument B (of 192 ohms) was shunted with a shunt of multiplying power $\frac{4}{3}$, or $1\frac{1}{3}$; the resistance of the shunt was therefore

$$\frac{192}{1\frac{1}{3} - 1} = 192 \times 3 = 576 \text{ ohms}.$$

(3.) What is the combined or joint resistance of the instrument and shunt together?

The joint resistance of two or more resistances in multiple arc is the exact converse of their combined conductivity para. 41). The combined conductivity as given before is

$$\frac{1}{\text{instrument resistance}} + \frac{1}{\text{shunt resistance}},$$

which, when brought to a common denominator, equals

$$\frac{\text{shunt resistance} + \text{instrument resistance}}{\text{instrument resistance} \times \text{shunt resistance}},$$

and the required joint resistance is the reciprocal of the above. We have, therefore,

$$\text{joint resistance} = \frac{\text{product of the two resistances}}{\text{their sum}}.$$

If, as is usually the case, the shunt is arranged for a definite multiplying power, n, we may arrive at the joint resistance from the value of n by a very quick and easy way. For it will be seen that if the expression above for the combined conductivity be split into two factors, one of which is the conductivity of the instrument, we have the combined conductivity

$$= \frac{1}{\text{instrument resistance}} \left(1 + \frac{\text{instrument resistance}}{\text{shunt resistance}}\right),$$

and the remaining factor enclosed in the bracket will be recognised as n.

Therefore the

$$\text{combined conductivity} = \frac{n}{\text{instrument resistance}},$$

and the reciprocal of this gives the

$$\text{joint resistance} = \frac{\text{instrument resistance}}{n}.$$

This latter expression is very frequently used, since n is generally known first and the joint resistance calculated afterwards.

Applying this again to the practical examples in para. 94, the joint resistance of A and shunt was

$$\frac{544}{5} = 109 \text{ ohms},$$

and that of B and shunt

$$\frac{192}{1\frac{1}{3}} = 192 \times \frac{3}{4} = 144 \text{ ohms}.$$

Although the calculations with shunts have taken some time to describe in words intelligently, it will be seen that the calculations themselves are very simple.

96. *Calculation of Actual Current through each Instrument and Plotting of Curves.*—Continuing the details of the practical example of the three instruments in para 94, after once adjusting the shunts, these have not to be altered again during the whole test, and therefore there is in the circuit a permanent resistance, comprising

Joint resistance of A and shunt	......	109 ohms
„ „ B „	......	144 „
Resistance of C alone	......	253 „
Battery		negligible resistance
		506 ohms

and with the permanent addition of 94 ohms in the resistance-box, the total resistance was made an even 600 ohms, this being increased by 100 or 1,000 ohms at a time, so that the resistance in circuit was conveniently always a multiple of ten. Two secondary cells of negligible resistance and 2 volts per cell having been used for this test, the main current passing through Instrument C corresponding to each reading was

$$\frac{4 \text{ volts}}{\text{total resistance}} \text{ in amperes.}$$

The current through B corresponding to each reading was $\frac{3}{4}$ of the above main current, and, similarly, the current through A was $\frac{1}{5}$ of the main current.

The curves were then plotted for each instrument in precisely the same manner as explained previously, each curve showing the relation between the deflections and corresponding currents through the instrument.

(To be continued.)

Minor Phenomena of the Incandescent Lamp.—We take the following from the *Scientific American*:—"The incandescent electric lamp has already been cited as giving an illustration of irradiation. When in full action, it presents no longer to the distant eye a simple loop of glowing carbon. By irradiation the outline is lost, and it resembles a gas flame. The same object illustrates very perfectly some of the phenomena of persistence of vision. If an incandescent burner is gazed at while near the eye the filament can be distinctly seen. Now, if the eye is closed, the image of the filament remains, and appears in clear outline in a purplish or violet colour. The characteristic shape of the particular filament is especially distinct. If, in looking at it, particular care is taken to avoid remembering its appearance (and this disciplining of the mnemonic faculty is not difficult), the spectral image seen with the closed eye will vividly portray the filament and its peculiarities. Sometimes it seems as if the effects of irradiation could be partly overcome; as if the image of a distant lamp could be reproduced free from the glow of irradiation. To a degree this may be possible, but a fully ignited and distant lamp always gives a confused spectral image to the closed eye. The filament of the high resistance lamps illustrates elasticity very well. Surrounded by a vacuum, so as to be free from the damping effects of the air, no object more sensitive to vibrations or shocks can be found. The least tremor of the wall to which the lamps are attached makes the loop vibrate for a long period. This only takes place when they are cold. When the current is passing and they become red or white hot, they are no longer so elastic, and cannot be made to vibrate as before. By the same vibrations sound is often produced. The vacuum of the globe prevents the sound from being heard by atmospheric transmission. But the filament is in solid connection with the globe and socket. If it is set in strong vibration, and the lamp is held pressed against the ear, a ringing metallic sound will be heard. This cannot be done with all burners. A certain size is naturally essential, as the sound is at best a weak one. It would seem possible that a visual seismograph of extreme sensitiveness could be made on the general lines of an incandescent burner. It is probable that a filament could be obtained in this way more affected by external vibrations than is the most sensitive device now used."

A MECHANICAL TEMPERATURE COMPENSATION FOR THE BIFILAR MAGNETOMETER.

The bifilar magnetometer is the instrument generally employed for determining the variations in the horizontal component of the earth's magnetism. When the observations are taken frequently, every hour for example, the corrections necessary on account of change in the temperature involve a large amount of laborious calculation. The effect of an increase of temperature is to diminish the magnetic moment of the magnet, and to increase the twisting couple due to the suspension.

In the *Zeitschrift für Instrumentenkunde* for January, Dr. Liznar describes a method by means of which he has succeeded in entirely obviating the necessity of calculating temperature corrections.

The torsion-head of the magnetometer is rigidly attached, by means of a brass collar, to the centre of a glass rod, which is thereby fixed in a horizontal position. This collar carries two other brass collars rigidly connected with it. Through these collars slide two zinc rods parallel to the glass rod, and capable of being fixed in the collars by means of screws. Two movable brass collars sliding on the glass rod and capable of being fixed in position by screws, carry adjusting screws by which the distance between the adjacent ends of the zinc rods can be regulated. The extremities of the platinum suspending wires are attached to these ends, and when the adjustment is made, the zinc rods are rigidly fixed at the desired points of their length to the glass rod by means of two double brass collars sliding on the rods, and capable of being tightened by means of screws.

The author shows that when the coefficients of expansion of glass, zinc, brass, and platinum are known, the available length to be given to the glass rod, in order that the increase of temperature may cause such an approach between the points of suspension as to keep the ratio of the magnetic moment of the magnet to the twisting couple constant, is determined—namely, the points at which the zinc rods are to be permanently fixed to the glass rod are determined. The author's method has been thoroughly tested, with the most satisfactory results.

In a series of observations with a magnetometer supplied with this arrangement, extending from January to June of last year, the temperature coefficient was found to be completely eliminated, having previously been about 3 scale divisions per degree centigrade. As the range of temperature was 6·78° C., the range of the variation in the readings, due to change of temperature, would have been at least 21 scale divisions.

G. W. T.

THE NON-EXISTENCE OF THUNDERBOLTS;

Elucidated by Accounts of Searches after them and the Exhibition of Specimens.*

BY G. J. SYMONS, F.R.S., SECRETARY.

The survival, down to the present day, of a belief in the existence of thunderbolts is a striking proof of the superficiality of modern teaching, and of the slight extent to which even the most elementary notions of electricity or physics have penetrated the mass of our countrymen. I hope that there is not one of our Fellows that has not long abandoned the belief; but, in case there should be one such, I have obtained the permission of our council to try to convert him.

Of course the belief in the fall of material substances during thunderstorms is merely the survival of the mythical bolts which irate Jupiter hurled at his enemies; but that the notion should still prevail with a population which may be said to be living in an age of electricity, and to be surrounded by telegraph, telephone, light, and bell wires, above our heads, below our feet, and running all through our houses, is passing strange.

Our President has illustrated to you that a flash of lightning is nothing but a large electric spark, an equalisation of potential between two unequally or differently electrified bodies; and there is no more transmission of a thunderbolt or any material substance than is there actual transmission of material substance when we send a message across (or rather under) the Atlantic.

* Read before the Royal Meteorological Society, March 21st, 1888.

I have been looking out for a real thunderbolt for over thirty years, and I am going to tell you very briefly the true history of several (so called).

Notting Hill.—On July 2nd, 1866, one of the London daily papers startled some of its readers by inserting a letter on the thunderstorm of June 30th, in which the writer said, "At six o'clock the storm broke out again with increased violence, the rain descending in torrents, and at a few minutes past seven a thunderbolt fell in the gutter opposite my house (in Westbourne Park, Notting Hill), and was smashed to pieces, one of which I have at the hour at which I write. Numbers of persons are still searching for the fragments."

Feeling certain that there was a weak point somewhere, inasmuch as "thunderbolts" have no existence, I called on the writer of the letter and other residents, found the story amply confirmed, received several pieces of the "thunderbolt," which were fragments of coal, a supply having been unloaded to the next house the day previous (by-the-bye, some were sold at 10s. and 15s. each), and eventually I ascertained that one of the pupils of an analytical chemist had availed himself of his tutor's absence to fill a capsule with materials calculated to burn vigorously and explode in heavy rain, and during the height of the storm, had thrown the burning mass into the gutter, so making an artificial thunderbolt. It is no wonder that the neighbourhood were taken in by a trick so well arranged.*

Kilburn, July 5th, 1877.—This is a very circumstantial story, and I am glad to be able to exhibit two pieces of the thunderbolt (?) and a photograph of the third. I append the account as given in the local paper,† but will summarise the leading features of what I believe to have been the real facts. A small street turning out of the Edgware-road, chiefly occupied by stables, contained also the premises of a local fire brigade. A telegraph wire crossed this street; an exceptionally strong flash of lightning struck, broke, and perhaps fused the wire; part of the wire fell on a little girl's hair and burnt it; other fragments fell in the street, where there was a blaze of light from the flash. Subsequently it was found that the street was strewn with clinkers—so called even by the newspaper—and these were described as thunderbolts. I think that most probably they had been raked out of the steam fire engine, but at any rate there are two difficulties which require expla-

* *Meteorological Magazine*, Vol. I., p. 66.

† FALL OF A THUNDERBOLT IN KILBURN.—The storm which burst over the metropolis about 8 o'clock on Thursday, 5th July, is described as being very severe in places, but it would certainly appear that Kilburn had the severest part of its viralence [*sic*], as a ball of fire of immense size fell in Bridge street, spreading consternation in every direction, but, happily, as far as the destruction of property is concerned, little or no damage is done in the street The telegraph wire, running from Mr. Carpenter's shop to Kilburn Park-road, was, however, completely fused, small fragments only being left, whilst the upper window of Mr. Brown's premises in Oxford-road was shattered. The scene is described as follows by several persons in the vicinity:—

"Shortly after eight o'clock a most vivid flash of lighning was observed, followed by a crash of thunder. This was succeeded by another, and then the most terrific crash, like the discharge of one of Krupp's guns, or the Woolwich infant, and with it fell the ball of fire or thunderbolt, to which we have alluded. This appeared to pass over with lightning rapidity from the direction of the Queen's Arms, and fell in huge masses into Bridge-street, from the door of the fire station up to the top of the street. The whole district for some seconds appeared to be enveloped in flame; the women screamed and in some cases fainted. The molten liquid, which poured down from the infuriated heavens, on reaching the ground at once coagulated, forming a clinker so heavy that in many cases they weighed over a pound and a-half. Meanwhile the place was enveloped in a thick bluish yellow smoke, very objectionable, which did not clear away for some ten minutes. Persons residing in the Kilburn Park-road made sure, from the spreading of the fire, that houses in Bridge-street had been struck and were in flames. A little girl named Frost, living at 6, Bridge-street, was struck on the head by some of the molten liquid and had her hair seriously burnt, but no dangerous symptoms are apprehended. After the flash of lightning alluded to, Bridge-street was literally strewn with a mass of clinkers; and it is estimated that were they all collected together there would be nearly two bushels of them, in size from a walnut up to a man's hand, and weighing very heavy. Simultaneously with the falling of the bolt in Bridge-street, as we have already noticed, the wire which crosses from the Post Office in Manor-terrace to the Kilburn Park-road was completely fused, small particles falling in every direction. . . . . . . Pieces of the clinker can be seen at the *Kilburn Times* Office.—*Kilburn Times*, July 7th, 1877.

Digitized by Google

nation :—(1.) How clinkers are formed in the sky ? (2.) Why they all fell in the street, and not one pierced a roof or broke a skylight ?

Chelsea.—On June 26th, 1880, at 3 p.m., there was a sharp thunderstorm in the west of London, and it was reported that a thunderbolt had struck No. 180, Oakley-street, Chelsea, and had been found in the kitchen grate. It was further stated that it had been broken up with the poker, but that a specimen could be seen at the office of the *West Middlesex Advertiser.* This sounded rather tempting, so I went. The lump which was shown to me was an agglomeration of brick, soot, unburnt coal and cinder. I suppose that no one would suggest that bricks are manufactured in the atmosphere, or that unburnt coal is another probable component. The case was unusual because ordinarily, on a lightning discharge descending a chimney beneath which a fire is burning, it scatters the burning coals over the floor. In this instance it seems, as usual, to have swept the chimney, taking down also some fragments of brick, and then finally to have fused the contents of the grate into a cake, thus producing this so-called thunderbolt. I am sorry that all the specimens have been lost.

Surrey.—I have not the date nor precise site of this fall; but, on the other hand, thanks to one of our Fellows, I have the thunderbolt (?). The story is very short. There was a thunderstorm, the lightning was seen to strike a manure heap; a hole was found in it, and on opening the heap this ball was found. Unluckily for the theory of the existence of thunderbolts this proves to be an old cannon ball! by which the direction of the flash had perhaps been partly directed.

Casterton.—Another illustrative case has come to my knowledge in connection with the present Exhibition. A large nodule of red sandstone has been sent, which had been found in circumstances which very naturally led to its having been regarded as falling from the sky; but it is simply a natural formation of the soil where it was found. The narrative runs somewhat thus :—A gentleman, his wife, and three daughters were looking out on a lawn at Casterton, in Westmoreland, during a thunderstorm, when they considered that they saw the stone fall through a tree, kill a sheep, and bury itself in the ground. After the storm the dead sheep was found, and a hole, and at the bottom of the hole this stone, which was forthwith described as a thunderbolt.

A very slight modification in the account will remove the romance, and show that the phenomena were of the most ordinary description. I venture to suggest that they saw the lightning strike the tree, the lightning killed the sheep, and then, as is not infrequent, in rushing into (or out of) the soil formed a hole. A nodule like this would be difficult of expulsion, and therefore the stone remained at the bottom of the hole.

There are several facts which have been twisted into imaginary support of the theory of the existence of thunderbolts

1st. There are the often approximately spherical nodules of iron pyrites which are so frequently found in the chalk. Their weight and their structure when broken harmonise so well with mythological notions, that it is not to be wondered at that many of them are still preserved as real thunderbolts.

2nd. Belemnites—which, by-the-bye, I see "Webster's Dictionary" says are called "thunderstones"—which are really fossil animals, are frequently preserved as thunderbolts.

3rd. If a heavy discharge of lightning falls on a bed of sand containing much silex it usually penetrates it for many feet; and along its path it fuses the sand into a sort of glass, thus producing what is known as a fulgurite (of which several very fine ones are in the British Museum). Portions of these fulgurites are sometimes considered to be thunderbolts. I regret that I have not been able to procure a specimen for the Exhibition, but there are two valuable drawings by Herr Dr. Fiedler, reproducing two—one of them nearly 9ft. long—of their natural size. And there is also a beautiful engraving of part of one in Ribbentrop's paper on "Fulgurites.*

* "Ueber die Blitzröhren oder Fulguriten," von G. Ribbentrop. Braunschweig: 1830.

4th. Sometimes aerolites or meteorites fall during thunderstorms. There is absolutely no connection between the two phenomena, but in the very rare cases where they have happened at the same time, the meteorite has, of course, been instantly designated a thunderbolt.

For our credit as Englishmen we ought to drive the word thunderbolt out of our dictionaries. Everyone can help to do this, and the greatest help of all will be, whenever one hears of a thunderbolt having fallen, not to content oneself with a shrug of the shoulders and an ejaculation as to popular ignorance, but to go to the spot, patiently examine the facts, and then explain publicly precisely what has happened. Thunderbolts require only to be brought to the light of modern knowledge to be at once annihilated.

THE DISTRIBUTION OF ELECTRICITY BY ALTERNATE CURRENTS.*

BY T. CARPENTER SMITH.

The distribution of electricity by means of alternating currents, though comparatively new in this country, has already reached such an enormous importance that it is with great hesitation that I venture to speak upon it, even though limiting myself to the strictly practical side of the work, dealing only with the apparatus as we receive it from the hands of the manufacturer, and leaving out entirely the question of the efficiency of dynamos and converters. It is only the knowledge that the mistakes of those who enter upon any new line of business are the rounds of the ladder by which we all attain success that emboldens me to lay before you some of the conclusions at which I have arrived after several years' experience of varied types of electric lighting, both by the arc, by the direct-current incandescent, and the alternate-current incandescent.

The subject naturally divides itself into several heads, but I would first say that it appears impossible to lay down any general plan of distribution, which shall be practicable in all cases. In almost every town a different plan will be required, and this will depend in most cases purely on local circumstances. Systems and methods that would be admirable for thickly settled and densely populated districts will not be successful in thinly populated and widely scattered ones. I wish it to be understood that, whenever I speak in this paper of success and successful systems, I mean successful entirely in a commercial way, and the conditions of this commercial success will vary in every town and district. I will therefore content myself with describing the method which I have found to be most successful in the various districts with which I have had actual experience, and leave it for those who may be called on to design and lay out the lighting of any particular district to judge for themselves which line of action to pursue.

Naturally, the first part of my subject is the dynamo, and the station detail. I have tried the large and small dynamo, and have concluded that it is a very great point to properly proportion the unit size of dynamo to the probable size of the station; that is, not to have dynamos of different sizes, but to first determine what the unit shall be, making it as large as possible, and then make your whole apparatus additions to that unit size. This simplifies matters very much, enabling machines to be interchangeable, both as regards their parts and their work, and this I am sure will be admitted by all who have ever had the annoyance of a breakdown on engine or machinery, when perhaps they had standing idle plenty of apparatus which, from various circumstances, could neither be used itself nor be robbed to repair the breakdown.

I would drive each dynamo by a separate engine, and this for several reasons. By proportioning the engine to the dynamo it will be possible to have the engine running slightly overloaded when the dynamo is doing its utmost during the hours of heavy lighting; and as this extreme load falls off to the lighter hours of running the engine will be working at its

* Paper read before the American National Electric Light Association, at Pittsburgh, Feb. 23.

Digitized by Google

point of best economy, instead of running underloaded, and thereby wasting steam. Thus, we use in our station on Virgin Alley dynamos of 2,500 lights capacity each, driven by 200 horse-power engines. During sixteen hours of the day these dynamos run, driving 2,000 lights, and the engines are cutting off at quarter stroke, and developing 200 horse-power. During the other eight hours we have driven these dynamos as high as 2,800 lights, during which time the engine was of course overloaded, and not working to so good an economy; but eight hours of overload is not nearly so wasteful as sixteen hours of underload. Again, we have had it very forcibly demonstrated more than once that if the engine be only large enough to drive the dynamo with ease, a heavy short circuit on the mains outside will simply pull the engine up or slow it down without destroying the dynamo, and only those who have seen a 9ft. fly-wheel running at 250 revolutions per minute on a 200 horse-power engine slowed right down in almost an instant of time can realise the terrific strain to which everything is subjected in such cases, and I would mention right here that the element of time is a very great factor in such circumstances, as in an accident of this kind mischief is often done before the safety catches can melt out. The direct belting of the engine to the dynamo is always to be preferred; shafting is, except under exceptional circumstances, simply a nuisance for incandescent electric light stations, and the economy of one large engine over many small ones has been enormously overrated. For arc light work, where the lights are all lit and extinguished at certain hours, the large engine is good; but for incandescent work, where the load is absolutely out of the control of the station, it is impossible to steadily run a large engine at anything like its most economical load, whereas, with separate engines, the machines can be started and stopped the moment that they are needed or are done with, while the oil from shafting will always cause more or less grease and dirt.

For central station use, except for very small plants, I should certainly use separately excited dynamos, and should do the exciting from two or more dynamos, each capable of exciting the whole system. In this way, with the station running at its normal, the only regulation required is that obtained by working the single rheostat in the field of the exciter, and, as we have designed our station at Pittsburgh, this will mean the regulation of 15,000 lights by one six-inch hand wheel. Of course, each dynamo should have its separate field rheostat, to make up for any slight difference in speed of engines. The two exciters should be so arranged that they can be run together or separately, or that either can do the whole work, which of course is easily accomplished by feeding them into a separate pair of exciter bars on the switch-board, and charging the fields of the alternating dynamos from these. The general question as to whether it is better to use separate circuits for separate machines, or to couple them into a general set of 'bus wires and distribute from them, is too large to be lightly decided, as also is the question as to whether it is best to run separate circuits for separate districts or to run into a general system of high-pressure mains outside of the station, feeding into these mains at different points, and again distributing from them; and I am not prepared to express any preference, but think that local circumstances will generally decide this question. There seems to me little doubt that in underground systems the network of high-pressure mains would be the best, but for overhead work we have adopted the system of separate circuits from separate dynamos, using a switchboard which enables us practically to run any circuit or any number of circuits from any dynamo, and running these dynamos separately and not in multiple arc. In spite of the utmost precautions, the unregenerate telephone and telegraph men are always hauling wires across our high-pressure mains and feeders, and while their wires and not ours generally suffer, after hearing the frightful roar that comes from the dynamo which is running the particular circuit so crossed, we always feel relieved to know that only one dynamo is in danger of being thrown out by the slipping off of the belt—and a 20in. belt is not a pleasant thing to have flying around loose. In case of any trouble, such as fire, circuit broken down, or anything of that sort, we can pull the switch of that particular circuit until we can cut out the part affected. The system that I have laid out for use here will of course take a long time to introduce, in view of the fact that we are changing from one system to the other, and have to be governed largely by the location of our lighting, our existing lines, and the possibility of putting up additional pole lines; but it takes, in my vision, the form of a series of heavy mains down the main streets, with cross lines on the cross streets, with switches on the poles, enabling any of the cross streets to be run from the mains on either of the main streets, so that, in case of fire on one of the main streets, the section represented by the block in which the fire occurs can, by the pulling of two switches, be completely cut off, while the cross streets on either side of the section will enable the lights beyond the fire or broken circuit to be operated, with only the trouble of a slightly larger percentage of loss and the consequent dimming of the lights.

For the main overhead wires I must harp upon the old string, which cannot be struck too often, namely, high insulation. For 100-volt current work the old stand-by of "undertakers'" wire will pass, but when it comes to 1,000 volts difference of potential, and 130 or 140 amperes to back it up, one realises very quickly that nothing is too good to curb this fiery steed. We are still paying the penalty of early ignorance in having many circuits of underwriters' wire stretched upon our poles, and I have stood and listened with fear and trembling to the howls of a new dynamo which had only been in operation for a few hours, when we had four short circuits in as many minutes, caused by dead wires falling across these mains on wet days; while, on the other hand, I have been gratified beyond expression to see our linemen remove ten or twelve old bare iron "district call" wires, which had been hanging all night right across our high-pressure, high-insulation mains, and this during a soaking rain. Especially should the service wires to the converters be of the best insulation, not only for fire, but for protection to life; for, while the shock does not kill, even a 100-volt shock may make a man start so as to fall off a ladder—and any death or injury will be credited to the electric current. We have adopted a standard of a separation of three feet between the two wires nearest each other on our cross-arms, and do not allow, under any circumstances, the tapping of service lines directly to these wires. All services must be attached through the medium of a small spreader on the end of the cross-arm, which I have no doubt all those present have noticed on the streets.

In some districts, where the number of lights in each building is small, we run secondary low-pressure mains, and place the converters on the poles, and make our distribution from our secondary mains; but our experience has been that this is not a very satisfactory way of doing. The percentage of loss on these secondary mains, unless the wires are very large or the converters very numerous, either of which is objectionable, causes such a decided variation in the lights as to give grounds for numerous complaints.

The question of the loss on the high-pressure feeders and mains is one which I think has not received enough attention. When the alternating system was first introduced, so much was said about the extreme smallness of the wire required that a great many of the arc light fiends throughout the country, who had been accustomed to congratulate themselves on the fact that No. 6 wire was big enough for a 20-mile circuit, immediately jumped to the conclusion that, because it was a high-tension current, No. 6 wire was big enough for all cases; and consequently more than one case of dreadful grief has arisen. I have laid out our circuits on a certain fixed plan, which is, that each circuit shall be laid out for 1,300 lights (that being the size of unit which we at first adopted), and made of such sizes as to carry these 1,300 lights with a loss of not more than 2 per cent. with the whole load on. By having feeders large enough for this we prevent any noticeable difference in candle-power from one end of the circuit to the other, and should we be even compelled to run a light circuit and a loaded one on the same machine the increase in the one or the decrease in the other would not be injurious. Of course we try to so arrange our circuits that the load shall vary about

Digitized by Google

the same on each, but the suddenness with which storms creep up in Pittsburgh makes our load very uncertain and erratic. We have run for three days and nights with only a little more than half of the machinery in operation, and then from Monday night to Friday morning have had to run every incandescent machine in the station under a load that fairly staggered it.

I now come to the question of the placing of the converters, and for this I think you may safely lay down the general rule that wherever you are simply carrying current do it at high pressure, and keep your low pressure for the purely local distribution. With proper precautions, I do not see that there is any real danger in carrying the high-pressure wires into and through the building. If a 1,000-volt current from a central station is not to be allowed in a building on account of its dangers, then every arc light plant—whether from central station or an isolated plant in the building—must be condemned for the same reason. Of course, the cases where two wires of an arc circuit with a difference of potential of 1,000 volts are run close together are not nearly so many as must be the case where there is a constant difference of potential of 1,000 volts in the alternating system; and again, of course, we have the fact that the direct current on arc circuits is generally not more than 20 amperes, while, as I have remarked before, our alternating circuits run as high as 130 amperes; but the fact that one is a direct and the other an alternate current largely makes up for this difference. With all due respect for the many gentlemen who have discussed so learnedly on the deadly alternating current, and on the frightful results therefrom, and whose experience with the alternating system is mostly confined to the magneto bell or induction coil, I must maintain that the alternating current, while it is in mild doses of from 100 to 200 or 300 volts intensely more disagreeable than the direct current of the same voltage, when it comes to 1,000 volts, or more, it is very much less dangerous to life. I make this statement with the more confidence that I have tried them both, and we have in our station here not one but half a dozen cases where our linemen and dynamo men have received the full 1,000 volts, generally being pretty badly burned at the point of contact, but experiencing no ill after effects; while, whenever any of our men receive a shock from one of our arc machines they are nearly always sick for a day after. This very fact of the alternating current being more disagreeable adds to its safety, as the men are disinclined to work on the wires, even when there is only a slight leak, where with the direct current they will often take much greater risks. In carrying our high-pressure wires through the buildings, we have adopted the invariable rule that they must be carried on porcelain insulators, and the wires themselves waterproof in all cases. We do not allow them to be run in moulding, but where the wires are to be concealed or protected, a casing is run around the wires outside of the porcelain insulators, giving them a perfect air insulation, and hard rubber must always be used for floors and walls. The converters are all placed with porcelain knobs behind them, giving an air space of two inches between them and the wall, and we prefer in all cases to put them against brick rather than against wood or plaster. I understand that in some districts the use of converters inside buildings has been forbidden, but I think that this position is a most unjust and untenable one. The only argument that can be brought against their being placed inside is the danger to life or of fire. For the first, the converter is well insulated, and is placed high up out of reach, and, most potent argument—though one I am sorry to say often refused recognition—it is not placed there to be handled. As regards the danger from fire, all the converters with which I have had any experience are boxed up completely in iron cases, the only opening in which is a small one at the bottom for ventilation. They cannot possibly get hotter than the melting point of lead, for the simple reason that if they should the fuses would blow out and cut them out of the circuit, and any one who has performed the old experiment of melting lead in a piece of paper, can easily see that this heat is not liable to set anything on fire, and even should the converter burn out, no flame can escape from it to set fire to anything, however inflammable. If the converter is to be banished from buildings on account of danger from fire, then every stove, high-pressure steam-pipe, and for that matter every gas jet, must also be banished.

In a Chinese firecracker lately published I find the statement that Inspector McDevitt has relegated to the cellar all converters, and that he says that in the first case of explosion or fire from them they will have to go to the street. Now, as vice-president of the company owning these converters, I have simply to say that this is not so, and that the converters are placed all through the buildings, wherever we may desire to have them, and only three or four are in cellars. Moreover, so far from Mr. McDevitt making any such statement, he has steadily refused, even under the most urgent solicitation of the Chinese gentlemen, to make any such restriction, but has very properly stated that until an explosion or fire occurred he can take no such action.

As regards the liability to burn out, and the danger therefrom, I can only say that from over 600 converters of all sizes, from five to fifty lights each, in an experience extending over twelve months of constant service night and day without any stop, we have had but three actual cases of burning out, two of these being 5-light converters, and one being a 50-light converter. The two 5-light converters were simply slowly roasted out from overloading, until finally the insulation on the primaries was charred through, when the fuse blew out instantly, and all was over. In one case the customer had been attracted by the converter singing, and was standing looking at it when his lights suddenly went out, and he had to go into a neighbour's store to know whether the trouble was in his lights only or with the main circuit. The 50-light converter suffered in the same way, having nobly endeavoured for some two days to run 120 lights. It was one of three on a section of secondary mains, and the lineman who had been sent out to examine them, owing to complaint to us of poor light, reported that two of them were all right, as they were cold, but that one of them was bad, as it was very hot; and preparations were being made to change this converter, when a message was received from one of our customers that the "stove on the pole" in front of his place was smoking.

Investigation showed that both plugs in the other two converters were blown, and the only reason that this one had not followed suit was the fact that some ingenious gentleman had made them of copper. We have had three cases of defective converters; that is, converters with a wire broken inside, or short circuited, so that the moment that the current was put into them they would blow out all the fuses, and if new fuses were put in they would again blow; but the men in these cases, of course, immediately returned them to the shop for examination. That is to say, out of the 600 convertors, we have actually had to remove or repair one per cent. in actual service; and I submit that, on a total convertible capacity of 17,000 lights, this is a very good proof that these converters are well made and not dangerous.

In all of our experience we have not had one single case of connection between the primary and secondary, or the primary and the shell of the converter, even in the case of the burned-out converters, and we had, just a few days ago, the first case of a connection between the secondary and the shell of the converter.

We started in with the idea that it was better in cases where we had, from the number of the lights in a building, to use more than one converter, to bank them—that is to say, connect all the primaries and all the secondaries in multiple, and distribute from this 'bus wire; but two or three peculiar experiences have led us to change our plans, and never to do so if it can be easily avoided. We had two or three unfortunate cases where one converter of a bank, for some unknown reason, would blow its plugs, thus overloading the others; then perhaps another would give way, and thereafter it was a race as to which would blow its plugs the quickest. It is not calculated to make one feel comfortable to have 400 lights in a theatre go out at once, just as the curtain is about four feet from the stage, in the beginning of the third act; yet this was our experience last Christmas Day. We had the converters fused up and running in half an hour, but next day the same thing occurred, though

Digitized by Google

the gas-man, seeing the lights dim down, was quick enough in shutting off his different circuits to stop three or four converters, which gave him lights enough to pull through. We have cut this building up, and each converter now carries its own load, with the result of our detecting one of them, which, for some reason unknown, always tried to do more than its share of the work; but while we have marked it, we have not troubled to change it, as, working singly, it does its work well. We have had another case of the same kind in another bank of converters, which have also since been cut apart, when we found the trouble arose from a poor connection which heated up the fuse to melting point; yet, as we have in the city hall two banks of twelve 40-light converters each, and in the union station a bank of twenty-three 40-light converters and three 20-light converters, which have never had the current off them for nearly three months, and have never had a single converter of all these blow its fuses, we cannot say that this result would always or even generally obtain; but as the object of banking is primarily to prevent the total extinction in case of one converter going out, and this is better attained by the judicious running of the secondary circuits, we prefer keeping the converters separated.

For the secondary wiring in the buildings we need lay down no laws. The rules governing this are too well known to need any repetition. One advantage of the alternating system, which was first brought to my attention by one of our wire men, is the fact that wires carrying the alternating system do not blacken the surface on which they run. We have in our station circuits of direct and alternating currents side by side, put up at the same time on a ceiling painted in very light colours, and which have been burning the same number of hours. The paint under the direct-current wires is very dirty, in the usual style, and the wires themselves are covered with a black deposit; while the alternating-current wires, and the ceiling on which they lie, are as clean as the day when they were put up.

There yet remains one point on which I wish to say a few words, and it is a subject of the greatest importance. Now that the alternating-current distribution is a pronounced success, there is no reason why the places of all others where incandescent light is most desirable, namely, in residences, should not enjoy the advantages and improvements from which they have hitherto been debarred by their distance from the usual centre of distribution, and it is when we bring electricity into the dwelling house, where it will be daily and hourly needed and handled by women and children, that we realise how absolutely necessary it is that we use anything and everything which can tend to make safe its introduction and manipulation. Of course the first, second, and third of these are, good insulation, better insulation, and best insulation; but besides this there are other points to be considered, and one that seems to be worthy of very careful consideration, and the fullest discussion is that which has been more than once suggested, namely, the making of a permanent ground connection with the secondary wires. The object of this, of course, is that should a leak occur at any point between the primary and the secondary, the current, being already grounded, will render it impossible for anyone to receive a shock by touching the secondary, and at the same time making an earth connection. When I first considered this question I said in my haste that this was not a proper course of action, as one is simply provoking a ground at some other point, and seeing the careful insulation of the converters we use I could not see any danger of a leak across; but I have since made up my mind not to come to any conclusion at all until I have considered and heard some discussion both *pro* and *con.*, and for this purpose I should like to hear the most bitter partisans on either side, that we may get from them every little weakness on either side of the question brought out.

In a paper like this it is impossible to do more than to give the mere sketch of the subject, but I trust that what I have said may be the means of inviting discussion and inquiry, for it is only by this means that we can arrive at the true facts of any case, and, as we all know, the electric light industry has suffered more than tongue can tell from the general ignorance of its dangers and requirements, which hindered and injured its early introduction into this country, and which led to the spending of so much good money on plants and wires which were not merely insufficient, but absolutely dangerous.

Now that we have taken, as it were, a new departure, and entered upon a new era of progress, let us not fall into the same errors which marred the early history of our business, but strive with might and main, by discussion and interchange of experience, to make each new installation another stride towards perfection in what I think is undoubtedly the greatest achievement of the age—the distribution of electricity by alternate currents.

ELECTRIC LIGHT STEAM ENGINES BY RANSOMES, SIMS AND JEFFERIES.

We are glad to find that many of our engineering friends are already feeling the benefit of the improvement in trade. Messrs. Ransomes, Sims and Jefferies (Limited), of Ipswich, who are always well to the fore with any new machinery, are now supplying a very complete series of engines—both portable and stationary—specially suitable, amongst other purposes, for driving electric light machinery.

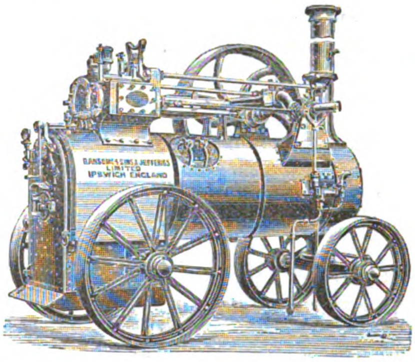

Fig. 1.—Compound Portable Engine.

The continuous necessity for engines which will economise fuel to the greatest possible extent has led to a large demand for "compound" engines, which, working at a high pressure, generate steam most economically, make use of its fullest expansive force, and thereby secure the largest amount of power for the fuel consumed. Fig. 1 shows one of Messrs. Ransome's compound portable steam engines, which are made from 8 to 20 horse-power nominal. The cylinders, which are placed side by side, are of the most suitable proportions to ensure steadiness in work. They are made with the outer shell and valve chests in one casting, the inner or working barrels, made of a special hard iron, being cast separately. The boilers are made of best quality mild steel plates, flanged and riveted by hydraulic machinery. They are proved to a high test pressure, and are capable of working continuously at 120lb. per square inch. The crank-shaft brackets, of wrought iron, are firmly riveted to the boiler, and also stayed to the cylinder by two strong wrought-iron tie-rods, thereby relieving the boiler of all strain.

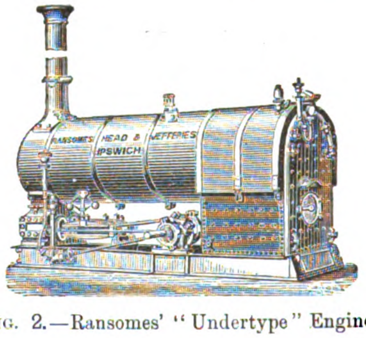

Fig. 2.—Ransomes' "Undertype" Engine.

In Fig. 2 we give an illustration of Messrs. Ransomes' "undertype" engine, in which the cylinder and working parts are placed on a strong, wrought-iron frame below the boiler. These engines are much in favour for electric light installations on account of their compact design—boiler and engine being self-contained—and the small outlay required for foundations. These engines are made on

Digitized by Google

the simple or compound principle, and with special expansion gear for ensuring regularity in speed.

The third illustration represents a long-stroke stationary engine, for which Messrs. Ransomes have already had many orders. This engine has found also special favour abroad. It is of the Trunk-Girder type, with disc-crank, and when fitted with Messrs. Ransomes' patent automatic governor expansion gear makes one of the most economical and best finished engines we have ever seen.

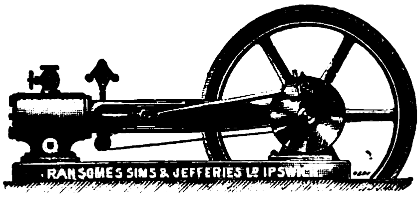

FIG. 3.—Long Stroke Stationary Engine.

Fig. 4 represents a compound stationary engine, the demand for which is steadily increasing, and of which Messrs. Ransomes have sent several of different powers to the Cape, India, &c. The entire engine-work is mounted on a strong wrought-iron frame, of channel section, which for shipment is taken to pieces so that the weight of the various packages may be reduced to almost any desired limit, a matter of extreme importance in countries where the inland carriage over bad and almost impassable roads is exceedingly costly, and next to impossible for large and heavy packages.

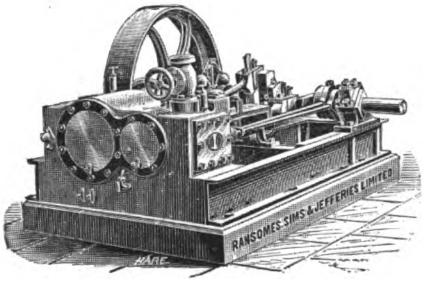

FIG. 4.—Compound Stationary Engine.

Steam is generally supplied by two separate boilers, arranged for a working pressure of not less than 120lbs. The two boilers, as a rule, are found more convenient than one larger boiler. They are made of mild steel plates throughout, and can be furnished for abroad with extra large fire boxes adapted for burning every description of inferior fuel. Each boiler is provided with a steam dome, and the connecting pipes between the boilers and the engine are entirely of wrought iron, giving lightness and strength. To each boiler is attached a suitable donkey pump. An injector is sometimes supplied in addition, giving thus, as an extra precaution, a double-feed arrangement. In some cases a separate surface heater is furnished, which raises the temperature of the feed water to boiling point, and is extremely useful in purifying the water when impregnated with lime or other foreign matter.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 10th*, 1888.

Interesting news comes from Washington with regard to the development of postal telegraph schemes. The Committee on Commerce of the House of Representatives has agreed to report favourably on the Bill, which creates a special bureau in the Post Office department. It is to be known as the Bureau of Postal Telegraphs, and is to be assigned to the care of a fourth assistant Postmaster-General. This functionary is to have trunk lines built wherever they may be wanted, and to employ the necessary staff. The rates fixed are 10 cents for twenty words for 500 miles, and proportionately larger for longer distances, 5 cents being charged for every additional ten words. The report which accompanies the Bill takes the shape of a long argument. The assertion that Congress has no power to pass such a measure is flatly denied, and, on the other hand, it is urged that public safety and convenience require the control of a telegraphic system by the Government. The report says in just so many words :—"Of all the monopolies, it is respectfully submitted that the telegraph system of the country, substantially owned and controlled by one man, is the worst and most dangerous;" and it is added, "The committee are still of opinion that the time has arrived when it is no longer safe or expedient to entrust to the hands of one overpowering monopoly the telegraphic business of this country. It is a power that not only can be used, but has been used, for purposes hostile to the best interests of the people." We are further told :—"The people are not in a mood to repose a trust of this character any longer without competition in the hands of a stock-jobbing corporation whose managers in the nature of things have not the slightest interest for the public good, but are alone concerned in the aggrandisement of their own fortunes." It will be seen that this measure contemplates the establishment of Government service in competition with and in opposition to the Western Union Telegraph Company. It may be very seriously doubted whether, even admitting the most serious charges and accusations against the Western Union Company to be true, Congress will vote for such a measure of confiscation. In abolishing evils that have had the recognition of the law, public opinion to-day, in all civilised countries, requires that there shall be some measure of compensation to those whose interests suffer, and where the question is one of this nature, upon which public opinion seems to be pretty evenly divided, it is utterly unlikely that any system of spoliation will be tolerated. In the meantime another Bill is reported from the United States Senate Committee on Post Offices with the object of controlling inter-State telegraphy. This Bill provides that it shall not be lawful to charge more for short-distance messages than for those transmitted longer distances in the same direction. A precedent for such a measure is to be found in the Inter-State Commerce Bill regulating railroad charges. Of the two Bills that I have mentioned above, that from the Senate stands by all odds the best chance of becoming law.

In our own State of New York the policy of interference thus in favour at the national capital is paralleled by the legislation based upon the recommendations of the committee which recently investigated the working of telephone companies. I sent you some account of this investigation at the time it was going on. The committee in their report arrive at the conclusion that the present telephone monopoly may be extended beyond the term of expiry of the present patents, by the taking out of other patents now in interference, and in other ways, and that the only remedy lies in the invention of a "make and break" system. That such an invention will be made appears to these gentlemen, upon expert advice, very uncertain. The committee also think that State Legislatures have no right or power to regulate the royalties charged by the parent company under its patents, but they hold that the charges made to subscribers by the local companies are liable to local restrictions. In their opinion there is but one circumstance which justifies legislative interference, and that is the levying of such charges as give local companies an undue return on their investment. This condition the committee consider to exist in only two cities in the State, viz., New York and Troy. In order to meet the case of New York, the committee present one Bill fixing the rate of subscription to be charged by the metropolitan company at $6.50 per month. At present it is $12.50. A second Bill provides that no stock shall be issued by local companies without an off-set in the shape of cash or securities. This measure is directly against the practice which has been followed by the parent company in accepting stock in part or whole payment for the local franchise. It will be seen that this is not a very sensational report; in fact, it confirms many of the arguments advanced by local companies, and goes to show that the stories of huge profits made by the local companies are almost wholly without foundation. Once more, too, the attempt to reach the parent company through State investigation and legislation fails of its purpose.

Speaking of the telephone reminds me that the Police Commissioners of New York have just made an important decision

Digitized by Google

with regard to the system of police signalling to be adopted by the city. As I wrote you not long ago, several systems have been on trial for a number of months, and the test has been a very severe one. The contract has now been awarded to the Herzog Teleseme Company, who use a signal box, which, operating upon the district messenger system, will turn in 300 or 400 different calls, and is so constructed that in case of several calls being turned on simultaneously to head-quarters, they are stored up, so to speak, and can be taken off *seriatim* and at will. In this competition the telephone played a leading part, being included as a necessary feature in several of the systems; but the commissioners came to the conclusion that for such work the telephone was practically unavailable, its inherent defects being insurmountable. For instance, one of the necessities of the case was that there should be some registration of the message sent, in order to avoid disputes, and to furnish evidence which would often have to be forthcoming. This, of course, the telephone could not give. Another objection to the telephone was that it would very often have to be used in noisy places, along busy thoroughfares, under the elevated railroads, and in the midst of turbulent crowds; hence it would be impossible to get even a glimmer of an idea as to what the excited guardian of the peace wanted to say. Then, again, each telephone call as it came in would require immediate attention and reply; but this could not be given without employing a large, unwieldy and expensive staff at head-quarters. There were other points of objection, but these, probably, were the chief. It is understood that the work of installing the new system will be begun immediately, and that £20,000 will be spent, to begin with, in equipping several of the down town precincts. The desirability of having any system of intercommunication between the policeman on his beat and head-quarters is apparent, and in adopting this new system New York is setting an example that many other cities may be ready to follow. This teleseme system has also been applied to hotel service, for which it is obviously very well adapted, and for which, I believe, it was originally devised.

Unless other cities hurry up, New York will be the first in this country to have a regular line of storage street cars in operation. A very neat station is now being fitted up on the Fourth-avenue line for the service of ten storage cars, and the plant will be in operation in May. The ten cars have been ordered and are now being built. Good results may be expected, as the work is being done all round in excellent style, and is in charge of Mr. C. O. Mailloux, an electrical engineer of great ability. The track upon which the cars will run is by no means of the best, and the other conditions are, as many of your readers know, far more onerous than those to be dealt with in Europe; but as the cars will be of intelligent and consistent design for the work they have to do, and will not be an experimental collection of ill-assorted parts, reasonable hopes of success are entertained. The only wonder to me is that with the heterogeneous jumbles of machinery that we have had up to date any sort of success at all has been attained. It is about time that protests were made against assigning to electricity tasks which no other agency could cope with, and then giving it the worst possible mechanism for the performance.

This is a day of combinations in America, and, of course, electricity has its share. You are already fully informed as to the compact existing between the Thomson-Houston, the Westinghouse, the Consolidated, and the Sawyer-Man Companies with regard to lamp manufacture, and the use of the alternating system. The Mather Company now appears to have come within the terms of this arrangement, having announced that it will supply its customers with Sawyer-Man lamps. Not satisfied with its large share of the lighting business, the Thomson-Houston Company, which established no fewer than 150 local companies last year, and had recently entered into an alliance with the Bentley-Knight Electric Railway Company, is now, it is reported, still further strengthening itself in the motor field by joining hands with the Van Depoele Company. As the Overhead Conductor Railway Company, which is practically an off-shoot of the Westinghouse lighting system, is already understood to be in close relationship with one or more of the companies just mentioned, it will be seen that the whole makes a very strong combination. In fact, so many leading companies have not been acting in concert since the days of the old Gramme combination which went to pieces a few years ago, but which, had it been held together, would undoubtedly have controlled the whole of the electric lighting business to-day in America. It is natural that much interest should be taken in the present state of affairs, and that many conflicting reports should find their way into circulation. How far the above defines the actual situation it is not easy to say positively, but it is believed to range near the truth, and to be correct in outline.

With the opening of Spring, the work in the department of electric railroading outside the large cities begins again in earnest. The past week has seen two new roads go into operation—those at Carbondale, Pa., and Wilmington, Del., both using the Sprague system, with overhead conductors. It may be noted, too, that a very favourable expert report on the adoption of electric motors for the street railways of Washington has been made to the Commissioners of the District of Columbia.

NOTES FROM BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The electric light is making extraordinarily rapid progress in this country. The following comparative statement showing the increase of installations in Berlin alone between March, 1886, and March, 1887, will give some idea of this progress; and it is believed that the rate has been well maintained during the last twelve months. The figures are the result of most careful inquiry, but it is of course impossible to guarantee perfect accuracy in a matter of this kind:—

	End of March, 1887.	End of March, 1886.	Increase.
Number of installations	333	152	181
,, of arc lamps	1,554	736	818
,, of glow lamps	22,363	12,705	9,568
,, of installations supplied by the central station of the Staedtischen Electricitätswerke	163	43	120
Worked by steam engines	124	79	45
Worked by gas engines	46	30	16

The twenty-six arc lamps in the Leipziger Strasse are not included in the above figures.

Taking each incandescent light to equal one gas flame, and each arc light to equal six gas flames, the above total number of lamps corresponds to about 31,687 gas lights, which is equal to about 4 per cent. of the total number of lights supplied by the Municipal Gas Works, and about 2½ per cent. of the whole number of gas lights in Berlin.

A large installation is in progress at Darmstadt. The cables, supplied by the firm of Siemens and Halske, are delivered; so also are the boilers, which are by Gohrig and Lemke. The whole installation is to be in working order by the 15th July. It will supply the Court Theatre, as well as a considerable number of houses in that district.

The regulations for the supply of the electric current by the Staedtischen Electricitätswerke at Hamburg have just been issued. The supply is compulsory from noon to sunrise daily. The customers are charged by meter, and have the option of purchasing or hiring meters at fixed prices. They also pay for their own glow lamps. There are very elaborate regulations and instructions as to the respective duties of the consumer, and the supplier in the event of a breakdown, either local or general. Current is supplied at the rate of 4 pfennige (equals ½d. nearly) per 50 watt-hours. This is at the rate of about 0·3d. per 10 candle-power glow lamp per hour, and for other sizes in the same proportion.

Arc lamps are charged at the rate of 1·38d. per hour for a lamp taking three amperes (say 300 candle-power), and for other sizes in the same proportion. The consumer has also to pay an annual charge of 5s. for each glow lamp, and 10s. for each arc lamp installed, whenever the daily average usage is less than 2½ hours. The municipal authorities reserve the right to revise this tariff list at the end of 12 months.

CORRESPONDENCE.

SUBMARINE OCTUPLEX TELEGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can you or your readers give me any information on the subject of the discovery mentioned by Mr. J. Henniker Heaton in his paper read last week before the Royal Colonial Institute ?

I refer to the invention that Mr. Heaton says has been brought forward "by which four messages can be transmitted each way at the same time along a single cable."

The question is one of some interest to me, as I was associated with the first practical application of duplex working on long cables, and as that system only gives one message each way at the same time, there is reason to fear that its days are numbered.

I have given close attention for some years to the subject of cable working, and I am surprised that not even a rumour of the new discovery should have reached me. In fact, until I read the report of Mr. Heaton's paper in *The Electrician* I was not aware that a single step had been taken towards the solution of the problem of the simultaneous transmission on long cables of even two messages in the same direction.

The discovery of a method by which four messages at once can be sent each way on such cables should bring fame and fortune to the inventor.

It is therefore somewhat surprising that, so far as I can learn, the system has not hitherto been brought to the notice of any of the existing submarine telegraph companies.

Can it be that the invention is not yet quite complete, and that those microfarads are giving trouble ?—Yours, &c.,

HERBERT TAYLOR.

4, Great Winchester-street, E.C., 21st March, 1888.

[We regret to say that we are unable to afford our correspondent any information upon the subject, the announcement contained in Mr. Henniker Heaton's paper being the first which has come to our knowledge. Possibly some of our correspondents may be able to give further information—or possibly it may be safe to treat the statement as a figment of the author's own imagination.—ED. *E.*]

ALTERNATE-CURRENT TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I noticed in your late issues a series of reports of the discussion on the above subject at the Society of Telegraph-Engineers and Electricians, which took place during my absence in America. Both Mr. Gordon and Mr. Crompton seem to be extremely doubtful of the possibilities of an alternating system, assuming certain details of working, on which the efficiency of the system must depend, to be impracticable. I allude to the coupling up of alternating machines in parallel and the use of small machines instead of large ones. My company having interests in this system of distribution of electricity I inspected several stations in the States equipped with complete Westinghouse plants. The practice in all of them was to use small dynamos, each dynamo running off a separate Westinghouse engine, the power being transmitted through a belt. They would have in the daytime a sufficient number of machines running to just supply the required current (thus obtaining a maximum efficiency of both engine and dynamo), and as the demand for current increases more machines are connected in parallel to the working system. The method of connecting in parallel has been brought to a simplicity that leaves nothing to be desired. The already working system and the fresh dynamo that is to be added to it are connected to two circuits on a small piece of apparatus showing by two lamps the difference of phase of the two currents. Each lamp varies from a maximum brilliancy to "black out" at a comparatively slow rate, and not coincidentally. The "beats" of the lamps alter in respect to each other, until in a few seconds the lamps go out and attain their maximum brilliancy at the same time. When this point is reached the switch is put up, and the machines are running in parallel without any disturbance taking place. Looking at the machine that is about to be switched on, the only evident sign at the moment of connection is a tightening of the belt from the load placed on it. One is bound to conclude, therefore, that the "bottom has been knocked out" of many of the arguments used in the course of the discussions above referred to, and that the consensus of opinion in this country in favour of distribution by means of transformers is fully justified and strengthened by what is being achieved daily in America.—Yours, &c.

E. MANVILLE.

Lambeth, S.E., 21st March, 1888.

STREET LIGHTING OF ENGLISH TOWNS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the letter of Mr. J. O. S. Elmore in your issue of 16th inst., to make your list of street lighting in English towns complete you must add Leamington, which, we believe, is the only instance in England of street lighting on the incandescent system in parallel. We have installed there 183 "Swan" 18 candle-power lamps. These are lighted during the ordinary hours of street lighting, and are paid for by the town at the same rate as their gas lamps, viz., £2. 2s per lamp per annum, including the lighting, extinguishing, cleaning, and renewing of the lamps. This works out at about 4d. per unit. The current is also supplied to the municipal and other public buildings, and to the residents and shopkeepers in the principal parts of the town, but in this case is charged for by meter, at a rate varying from 8d. to 4d. per unit, and is measured by our Mr. Hookham's patent electricity meter.—Yours, &c.,

CHAMBERLAIN AND HOOKHAM (LIMITED).
J. BROWN, Secretary.

Birmingham, March 21, 1888.

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: However great the differences of opinion existing between electric light contractors and fire office inspectors, the advent of two more sets of rules, in addition to those of the Phœnix Fire Insurance Office, will not tend to simplify matters.

It is to everyone's interest to reduce electric lighting to its simplest form—an object which will certainly not be forwarded by having various authorities all looking at the subject from their own point of view. The stage to which matters have come has more especially been brought under my notice by my having been asked to draw up a set of fire office rules for one of the larger fire insurance offices. The effect upon the public mind will hardly be reassuring when they have to choose between conflicting opinions, every one of which is said by its upholder to be the one and only way of carrying out electric light installations. Whilst one does not wish an approach to the "go-as-you-please" license given to gas engineers, one does not wish to fall into the opposite extreme of having to take useless precautions. I had hoped that the days of firms putting in second-class material and scamping their work were coming to an end, but the time for this seems likely to be still further prolonged if there are several standards of work.

Unless the Society of Telegraph-Engineers or the "Dynamicables" will take the matter up in a broad-spirited way, it would be as well to have a meeting of those interested, and for them to appoint a committee, consisting of representatives of the fire offices, electrical societies, consulting engineers, electric lighting firms, &c., to draw up a set of rules. The present Phœnix Fire Insurance Office Rules might be taken as a basis, and altered or added to so as to include any points considered advisable by the committee. Finally, let this one set of rules be acknowledged, as it probably would be, by the fire offices, electric societies, and profession generally as the standard by which work must be carried out.

It might be of advantage to have a committee of appeal for new and disputed points in installation work, and there also might be a definite list of risks made out for different classes

Digitized by Google

of buildings, such as theatres, private houses, mills, &c., together with the class and description of insulation that would be passed for such risks, this probably varying with the different systems of lighting and the rate at which the building is insured.—Yours, &c., F. L. RAWSON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: "Electrical Contractor," in his letter of the 16th inst., puts the question of fire insurance rules in a very forcible manner.

I do not think there is the least doubt that if only electrical contractors as a body had been consulted they would have given a unanimous verdict against the issuing of fresh rules, or interfering with those that have so long held the field. These new rules are solely attributable to the unsuccessful attempt on the part of the Society of Telegraph-Engineers to obtain for themselves the credit of having originated the only recognised insurance rules in existence. If there is a clique who seem to have tardily discovered the fact that they have had no hand in the issuing of these rules, and have any objections to them, why do they not come forward and state these objections? If they did this I feel confident that the Phœnix Company would be only too glad to entertain any reasonable suggestions they might make in order to render their rules as perfect as possible. This issuing of fresh rules will create the utmost trouble and confusion, especially amongst good and first-rate firms, who will be cut out altogether by those who will take advantage of a multiplicity of rules to put up cheap and bad work, besides unnecessarily alarming the public, who will immediately take it for granted that if electricians cannot mutually agree how to put up installations there must be very considerable danger run in adopting the electric light.

In future, how are specifications to be drawn up for installations? which set of rules will be taken as a basis of the way in which the work is to be executed? Supposing a building is fitted with the electric light, and insured in several offices, each having its own set of rules, how will it be possible for the contractor to get his work passed by the various insurance inspectors if each is going upon his own lines? Hitherto where a case has arisen as above it has nearly always been sufficient to inform the other insurance offices that the installation had been put up in accordance with the Phœnix Fire Office rules and passed by Mr. Heaphy.

Now all this will be changed, and contractors will have a sorry time of it. Consulting electricians will also be powerless to better the situation, as they cannot hope to get rival promoters of rules to agree to any but their own.

This question is of such momentous importance to all electrical firms, that unless a combined movement be made, and that at once, to counteract this action, a blow will be struck at our industry from which we shall suffer long and severely.

As it seems to be a question that only concerns electrical contractors, and not telegraph engineers, professors, or other learned scientists, the former should at once take steps to bring forward their united opinions, and in so doing I hope there will be many who will share the views of

ANOTHER ELECTRICAL CONTRACTOR.

March 20th, 1888.

PROPOSED METHOD OF RENDERING RETARDATION OF PHASE VISIBLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been trying, as suggested by you in *The Electrician* of March 9, whether, when the vibrator of an induction coil is illuminated by a Geissler tube placed in the secondary circuit, the change of phase of the current in the secondary obtained by varying its coefficient of self-induction can be made large enough visibly to affect the position of apparent rest of the vibrator.

I find that the motion of the vibrator can be magnified quite sufficiently for the purposes of private experiment by attaching to it a stiff straw whose direction is a prolongation of the spring, and that if the Geissler tube and a paper scale be placed immediately behind the straw the position of rest which it seems to take up can be determined with considerable accuracy.

In the secondary circuit I introduced the secondary of a much larger coil, whose primary remained open and whose core was adjustable and could be removed altogether. I found, however, that no perceptible difference in the position of the straw resulted either from the motion or removal of the core, or even from the short-circuiting of the coil itself.

The reason for this is not far to seek. It is, of course, impossible to speak of the resistance of a Geissler tube, but we may, for our purpose, suppose it replaced by a variable resistance. The smallest value of this resistance will, however, be extremely large, so large that with a moderate speed of interruption no perceptible difference of phase will be produced by the addition of the largest practicably attainable amount of self induction.

I have not yet found a satisfactory method of magnifying the motion of a Spottiswoode's rapid break, which I should like to substitute for the vibrator. I am afraid, however, that even if the experiment in that form could be carried out in the laboratory it would hardly be possible to adapt it to the requirements of the lecture room.—Yours, &c.,

L. R. WILBERFORCE.

Cavendish Laboratory, Cambridge, March 17, 1888.

RED VARNISH FOR INCANDESCENT LAMPS FOR A PHOTOGRAPHIC "DARK ROOM."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If I remember rightly there was given in *The Electrician* some time back a receipt for making a red varnish for incandescent lamps. I want to use one in a photographic dark room, and should be much obliged if you or any of your readers could tell me the quantities of the different ingredients that would be required to make a varnish of the necessary darkness. I have not got the back numbers of *The Electrician* out here.—Yours, &c., J. E.

Mexico, February 23rd, 1888.

[A correspondent who is an authority upon the subject of photography, and to whom we have submitted the above letter, has kindly written as follows:—

"I have much pleasure in telling you what I know about the matter. If your correspondent wants to set up a photographic dark room, he presumably has some negative varnish, and if so he has only to stain a little of it with 'fuchsine' to make a red varnish suitable to the purpose. The question of how deep the stain must be depends on several considerations, as the colour of the carbon when incandescent and the nature of the work to be done in the dark room.

"In connection with this point a most interesting inquiry presents itself, namely, to what extent is it worth while to varnish the lamp at all, seeing that almost any amount of *red*ness can be obtained by simply lessening the current passed through the carbon? What, in short, do you gain by raising the carbon to a state of high incandescence, and then cutting off the actomic rays by a red screen? Whether the lowest or '*red*-hot' stage of incandescence would be a safe light for modern photographic plates without any further protection is a question I cannot answer offhand, but I am sure that a '*red*-hot' lamp would only require a slight tinge of red in the varnish to render it safe, whereas if the incandescence is pushed, say, to three watts per candle, a very deep stain would be required which would cut off all, or nearly all, the light gained by the extra heat of the carbon."]

THE STABILITY OF OVERHEAD WIRES.

We have received a further letter of considerable length from Mr. Caws, but we think that it is now quite time to close this discussion, and therefore we merely give the latter part, which is as follows:—

"I remember calculating a year or two ago for an iron wire of 100 yards span *the dip which would remain constant for all*

Digitized by Google

temperatures. It was not very different from the dip in common use as given by Brough's tables.

"At the constant dip of a catenary, the expansion and elasticity, being exactly equal and opposite forces, continually neutralise each other at all temperatures.

"But for copper catenaries the constant dip cannot be well employed in outdoor practice, for owing to the coefficient of expansion for copper being 50 per cent. greater than for iron—though the elastic modulus for iron is 50 per cent. greater than for copper—the tension of a copper wire at which the elasticity and expansion neutralise each other is too severe to leave enough reserve strength to meet storms and extra strains generally. Hence the necessity of spring shackles for copper lines.

"Those old books to which Mr. Preece has now referred me are very useful, but not to the point at issue. I have much pleasure, however, in inviting Mr. Preece's attention to a new paper dealing specially with the question theoretically and experimentally, viz., '*Conditions d'equilibre d'un Fil de Bronze Phosphoreux tendu entre deux appuis.*'

"The very able author, M. Cloeren, of Brussels, has kindly sent me a copy, accompanied by an expression of his satisfaction at the Monkwearmouth experiments.

"When Mr. Bozon seriously 'corrected' me for leaving the weight of my dynamometric apparatus to bear on its own proper side of the scale, and for not confounding it with the span which constituted the weight on the other side of the scale, I could not help laughing at such a 'bull.' But I had not the faintest intention of being 'personal,' and if my jocular observation wounded his *amour propre* I ask Mr. Bozon to let them pass; for it is well known that the cleverest of men are sometimes notorious for making 'bulls' of the most laughable character.

"On page 504 *The Electrician*, October 21, 1887, Mr. Bozon will find the question of chafing discussed, and the way to prevent it pointed out."

A LINESMAN'S LAMENT.

TO THE EDITOR OF THE ELECTRICIAN.

Ere winter, Sir, you had your fling
  At them there monkeys yonder,
Who on the wires for pastime swing,
  And break 'em down like thonder.

Well, nigger monkeys may be bad,
  Most gymnerasteric things, Sir,
And Brazil linesmen may be glad
  To get them Caws's springs, Sir.

But homebred snowflakes let me back
  Agin all monkeys goin';
They're white, 'tis true, but then, alack!
  The De'il is wi' them blowin'.

They drop by millions on the spans,
  Soft footeder than Fancy,
And who among us unnerstan's
  Their wicked dill-y-dancy?

So fast it falls, so close it clings,
  That in a magic trice, Sir,
These flyin' monkeys fold their wings,
  And there's your rope of ice, Sir!

Than all the tropic monkey kind,
  In spite their summer trainin',
This frigid imp of snow and wind
  Is mischiever at strainin'.

Them springs will hold till all is blue,
  Wi' snow and wind together,
Yet "gie the verra De'il his due,"
  By humourin' his tether.

By civil dodgin' to and fro,
  They'll mischief circumvent, Sir;
Then, let the blastin' Blizzards blow!
  And give the Furies vent, Sir!

If you could see this ruined line!
  Not half on't mended yet, Sir;
You'd surely make these lines of mine
  Your nextest leaderette, Sir.

North Britain, March 16, 1888. DANIEL WALKER.

PHYSICAL SOCIETY.

At the meeting of this society, held on the 10th inst., the first paper was read by Mr. G. L. Addenbrooke

"ON A PORTABLE REFLECTING GALVANOMETER."

(This paper we reproduced in our last.)

Mr. E. C. RIMINGTON then read a paper on

"The Measurement of the Power Supplied to the Primary Coil of a Transformer,"

This method gives a means of measuring the power supplied to the primary by one reading of a high-resistance Siemens dynamometer without knowing either the resistance or coefficient of self-induction of the primary. The arrangement employed is shown below:—

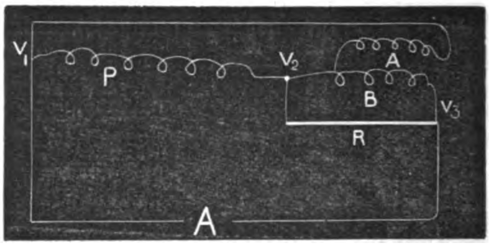

FIG. 1.

P is the primary coil, R a non-inductive resistance, A alternating-current dynamo, V_1, V_2, V_3 potentials at the ends of the primary coil, and the resistance R. A and B coils of a high-resistance Siemens electro dynamometer.

Let r_1 and L_1 be the resistance and coefficient of self-induction of the coil A, r_2 and L_2 those of the coil B. Let s_1 and s_2 be the impedances of the coils A and B respectively, i_1 and i_2 the currents in them, and ϕ_1 and ϕ_2 their angles of lag; let ϕ be the angle of lag of the primary coil. Let δ be the reading on the dynamometer, and k some constant.

Let $$\frac{L_1}{r_1} = \frac{L_2}{r_2}.$$

Now $$\tan \phi_1 = \frac{a L_1}{r_1} = \frac{a L_2}{r_2} = \tan \phi_2;$$

$\therefore \phi_1 = \phi_2$; where $a = \frac{2\pi}{T}$, T being the periodic time.

Let E_1 and E_2 be the maximum values of the potential differences between V_1 and V_2 and V_2 and V_3 respectively.

Then, $$\delta = \frac{k}{T} \cdot \frac{E_1 E_2}{s_1 s_2} \int_0^T \sin(a t - \phi_1) \sin(a t - \phi - \phi_2)\, d t$$

$$= \frac{k}{2} \cdot \frac{E_1 E_2}{s_1 s_2} \cos(\phi_1 - \phi_2 - \phi) = \frac{k}{2} \cdot \frac{E_1 E_2}{s_1 s_2} \cos \phi.$$

Now the power supplied to the primary coil or

$$p = \frac{E_1 E_2}{2 R} \cos \phi = \frac{\delta}{k} \cdot \frac{s_1 s_2}{R}.$$

If $\frac{K}{R}$ is the constant of the dynamometer for watts with a steady current

$$k = \frac{r_1 r_2}{K}$$

$$p = \frac{K}{R} \delta \frac{s_1 s_2}{r_1 r_2}.$$

But $$s_1 = r_1 \sqrt{1 + \frac{a^2 L_1^2}{r_1^2}} = r_1 \sqrt{1 + \tan^2 \phi_1},$$

and $$s_2 = r_2 \sqrt{1 + \tan^2 \phi_2}.$$

Hence $$p = \frac{K}{R} \cdot \delta \cdot (1 + \tan^2 \phi_1),$$

where $$\tan \phi_1 = \frac{a L_1}{r_1} = \frac{a L_2}{r_2}.$$

L_1 and L_2 can be found by any of the well-known methods of determining coefficients of self-induction, and r_1 and r_2 adjusted so as to satisfy the above condition by putting non-inductive resistances in series with the dynamometer coils. By making r_2 the movable coil and giving it a value considerably less than r_1, R may be made in the same proportion less than the impedance of the primary coil P, thus avoiding the waste of much power in R.

Prof. AYRTON considered the method very inferior to the one described by him at the Society of Telegraph-Engineers, and illustrated in *The Electrician* of Feb. 24, as Mr. Rimington's method,

while open to the same objection as the one due to himself and Prof. Perry, of wasting power by the introduction of resistance in series with the primary, presupposes in addition the rate of alternation to be known.

It was unnecessary to use Joubert's method to determine the coefficient of self-induction of the primary circuit, as the effective coefficient of self-induction was at once calculated for each of the experiments by the following formula :—

$$L = \frac{r}{\pi} \sqrt{\frac{\overline{V}^2}{\overline{A}^2} - r^2}.$$

Where $\overline{A}$ and $\overline{V}$ are the square root of mean squares of amperes and volts respectively, given in columns headed *b* and *a* in *Electrician* of Feb. 24, p. 421.

The Professor stated that the formula $d = k\,(A - B)\left(C - \frac{A+B}{2}\right)$ (*Electrician*, Vol. XX., p. 420) suggested to Mr. Sayers, one of his former students, a method of constructing a direct-reading wattmeter for alternate currents, for by making C large in comparison with A and B, $\frac{A+B}{2}$ becomes negligible in comparison with C. Now if the quadrants of the electrometer be connected respectively with the two ends of the non-inductive resistance *r* (Fig. 2, *Electrician*, p. 420), instead of with A and B, and if the needle be connected with the other end of the primary coil of the transformer; in other words, if R and *r* change places, C will in practice differ from A and B by some 2,000 volts or more; hence we have

$$\frac{d}{k\,r} = \frac{A - B}{r}\,C,$$

and the power given to the primary circuit is at once obtained from the reading of the electrometer.

He considered a great desideratum at present was a method of measuring directly the power given to any circuit possessing self or mutual induction, or both, and traversed by an alternating current which was any function (not necessarily a sine function) of the term without requiring the introduction, in series, of a resistance, and without requiring a knowledge of the rate of alternation.

Mr. T. H. BLAKESLEY stated that he had devised such a method. The arrangement used by him is shown in Fig. 2.

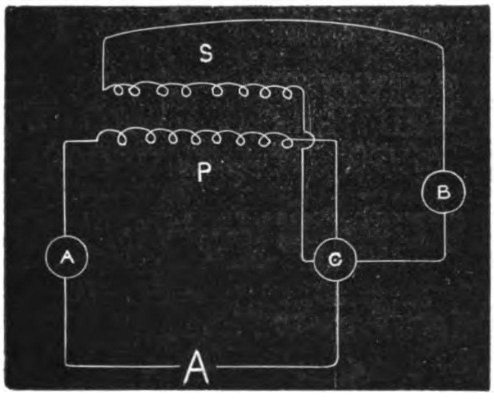

FIG. 2.

Let *m* be the number of coils in the primary, and *n* the number in the secondary.

Let α, β, γ be the readings of the three dynamometers respectively, and A, B, C their constants.

Let r_1 and r_2 be the resistances of the primary and secondary circuits respectively.

Then he finds that the total power supplied is given by the formula

$$A\,\alpha\,r_1 + r_2\,\frac{m}{n}\,C\,\gamma,$$

and the loss of power due to hysteresis by

$$r_2\left(\frac{m}{n}\,C\,\gamma - B\,\beta\right).$$

In reply to a question by Prof. Ayrton, Mr. BLAKESLEY stated that in obtaining these formulæ he recognises the existence of an angle of lag, but he makes no assumption with regard to the constancy of the coefficient of self-induction. The formulæ were obtained by geometrical reasoning, without the use of differential equations.

Mr. SUMPNER pointed out that the geometrical method of Mr. Blakesley involved the assumption that the electromotive forces and currents were all sine functions of the time, and that this assumption was erroneous unless the coefficient of self-induction could be considered constant. The angle of lag was subject to the same kind of variation as the coefficient of self-induction. He (Mr. Sumpner) hoped soon to bring to the notice of the society experimental evidence to show that the coefficient not only varied with the magnetising current and with the previous history of magnetisation, but that it always had two distinct values, according to the direction in which the current was about to be changed.

Mr. RIMINGTON, in reply, considered that an objection to Prof. Ayrton's method lay in the fact that electrometer deflections are usually small. He was of opinion that it was not a valid objection to his method that it presupposed a knowledge of the rate of alternation, as in most cases which occur in practice this can be determined.

Prof. PERRY then read an abstract of a paper by Prof. Ayrton and himself

"On the Magnetic Circuit in Dynamo Machines."

The authors have worked out a number of formulæ for dynamos, involving, not the number of coils on the armature, but the thickness *t* of the winding and *a*, the highest permanent current in amperes per square centimetre of the cross-section in that winding. All the numbers given in the formulæ, with the exception, of course, of volts, amperes, and watts, are in C.-G.-S. units. One of these is

$$W = \frac{2\,v\,N\,t\,a}{10^8} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

where

W = highest permanent power or output developed,
v = circumferential velocity in centimetres per second,
N = total highest permanent magnetic induction through armature.

Then as the armature winding is thin $t\,a^2 = q^2$, a constant. In the case of some armatures which are always cool the value of q is about 150, but in the best modern machines its value is generally about 288. In some machines it is considerably over 300, but there is then undue heating. For fine wire the value of q is less.

The output can now be expressed in various useful ways; for example,

$$W = \frac{2\,q}{10^8}\,v\,N\,\sqrt{t} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

The value of N is given by

$$N = \frac{\frac{4\pi}{10}\,S'\,A'}{\frac{2\,(d+t)}{a_2} + \Sigma\,\frac{l\,\nu}{a\,\mu}} \quad . \quad . \quad . \quad . \quad . \quad (10)$$

S′ A′ being ampere turns on one magnetic field-magnet circuit, d the clearance between the armature-winding and the pole-piece, a_2 the area of the pole-piece exposed to the armature (increased by a fringe all round of breadth 0·8 $(d+t)$), a the cross section of any iron part of the magnetic circuit of length l, through which there is an induction, ν N, the magnetic permeability being μ. From this it follows that W is a maximum when

$$\frac{2\,t}{a_2} = \frac{2\,d}{a_2} + \Sigma\,\frac{l\,\nu}{a\,\mu}\,;$$

that is, when the magnetic resistance of the space occupied by the winding on the armature is equal to the sum of the other magnetic resistances of the circuit.

The value of this rule is very great. For example, we have

$$W' = \frac{2\,\pi\,q}{10^9}\,\frac{v\,a_2}{\sqrt{t}}\,S'\,A' \quad . \quad . \quad . \quad . \quad . \quad (13)$$

The authors, after giving Frölich's and other formulæ for the law connecting N and S′ A′—that is, "the characteristic of the dynamo"—state that they had wasted much time in trying to obtain a simple formula, the constants of which could be calculated from the dimensions of the component parts of a machine. While giving all credit to the Drs. Hopkinson for their valuable study of the dynamo, they point out that Messrs. Hopkinson had not been able to calculate the characteristic for an existing dynamo with what could be called accuracy, and that for all practical purposes the following rule, based on (12), is sufficiently accurate :—

1. For values of N equal to more than half the maximum value, it is only necessary to study the air resistance, and write,

$$N = \frac{\frac{4\pi}{10}\,S'\,A'}{\frac{2\,(d+t)}{a_2}}$$

Let the straight line given by this be drawn upon squared paper.

Digitized by Google

2. The maximum permanent value of N is $\alpha_1 \beta_1$, where α_1 is the diametral section of iron in the armature, and β_1 is a maximum permanent induction whose value in good machines ranges between 17,000 and 18,000.

Find the value of S′ A′ from the formula—

$$N = \frac{\frac{4\pi}{10} S' A'}{\frac{4t}{a_2}}$$

and plot these values of N and s′ A′ as rectangular co-ordinates of a point on squared paper.

Any one who has been accustomed to draw characteristics of dynamo machines will be able to draw a curve through this point, touching the straight line, which will not differ materially from the characteristic of the constructed machine.

In testing this rule on the Manchester dynamo the authors were afraid to trust to their judgment, as the real characteristic was already known to them.

They therefore assumed a curve

$$N = p \tan^{-1} (k \, . \, S' A'),$$

and determined it by the conditions that it should be tangential to the given straight line, and should pass through the given point, and the curve so obtained is shown in the original paper, drawn on the same sheet of paper with the curve calculated by Dr. Hopkinson, and the one obtained from the observations.

They state that in the best modern machines for incandescent lighting, the only place in which "throttling" of the induction is allowable is in the armature; but the usual rule now is to have β constant everywhere, that is to have no throttling anywhere.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

STUDENTS' MEETING.

A students' meeting was held on Friday last, the 16th inst., Mr. W. M. Mordey presiding.

Mr. Mordey made some remarks in regard to arbitrary units, and explained the system adopted by the Anglo-American Brush Electric Light Corporation for numbering wires and leads.

Mr. A. H. Dykes then opened a discussion upon transformers, which was continued by Messrs. Smith, Lamb, Cooper, Tidd, Collis, Zingler and Mordey.

The meeting then terminated after passing a vote of thanks to the Chairman.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

15,878A. VICTOR POPP. London. New or improved apparatus for measuring the time during which a current of electricity or other fluid is flowing. November 18, 1887. (Note.—This application having been originally included in No. 15,878, dated November 18, 1887, takes under Patents Rule 23 that date.)

3,672. H. EDMUNDS. London. Means or appliances for use in connection with electric circuits or water or gas supplies or the like, to enable a supply of electricity for lighting or other purposes, or a supply of water or gas, or the like, to be obtained on the deposit of an equivalent therefor in the shape of prepayment or otherwise. March 9, 1888.

3,678. W. G. OLPHERTS. London. Improvements in and relating to electrical signalling or railways and in apparatus therefor. March 9, 1888.

3,685. S. SHARP, J. M. V. MONEY-KENT and H. J. PAYNE. London. Improvements in electrical switches. March 9, 1888.

3,690. E. DUNN. Forebridge, Improvements in railway electrical signalling apparatus. March 10, 1888.

3,710. J. TWEEDALE. Glasgow. Improvements in electro-magnetic motors. March 10, 1888.

3,714. A. C. COCKBURN and F. DAY. London. Improvements in electrical fittings. March 10, 1888.

3,740. A. BERNSTEIN. London. An improved combined cut-out and switch. March 10, 1888.

3,812. E. L. BERRY and G. FRANKE. London. An improved combined switch and holder for electrical incandescent or glow lamps. March 12, 1888.

3,835. H. P. COPELAND. Manchester. Improvements in telegraphic apparatus. March 13, 1888.

3,883. A. J. BOULT. London. Improvements in electrical devices for type writers (J. F. McLaughlin, United States). March 13, 1888.

3,921. T. PARKER, E. SCOTT, G. REES, and J. H. WOODWARD. Manchester. Improvements in apparatus for indicating, measuring and controlling electrical currents. March 14, 1888.

3,929. T. PARKER, E. SCOTT, G. REES, and J. H. WOODWARD. Manchester. Improvements in and relating to dynamo-electric machines. March 14, 1888.

3,968. J. W. KING. London. Regulation of feed of arc lamps. March 14, 1888.

3,979. W. G. JOHNSON. London. Improved construction of plates and arrangement of fastenings for connecting them in voltaic order for medico-electric purposes. March 14, 1888.

3,981. E. HOPKINSON. London. Improvements in and connected with means for driving, controlling, and working electrically propelled vehicles, cranes, and the like. March 14, 1888.

3,986. B. M. DRAKE and J. M. GORHAM. London. An improvement in plates for secondary voltaic batteries. March 14, 1888.

3,995. H. H. LAKE. London. Improvements in and relating to galvanic batteries (H. Walter, United States). March 15, 1888.

3,993. T. C. R. HORSFIELD and R. PORTER. London. An improved electrical indicator for the locking apparatus connected with railway points. March 15, 1888.

4,008. H. ULLATHORNE and C. GAUZENTES. Bradford. Improvements in electric batteries. March 15, 1888.

4,107. G. E. DORMAN. Stafford. Improvements in electric arc lamps. March 15, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the dates in italics, give notice at the Patent Office in the prescribed form of such opposition.*

March 17, 1888.

LEGAL INTELLIGENCE.

The United Telephone Company v. The Equitable Telephone Company.

A motion for an injunction on behalf of the United Telephone Company was made on Friday morning last, before Mr. Justice Chitty, to restrain the Equitable Telephone Company from infringing the patents for telephones of the plaintiff company. The United Telephone Company being proprietors of the patents for telephones in which carbon is used, have established their right in the patent in the course of several actions, and the instruments are in general use rented from the plaintiff company. The defendant company was registered with a small capital in December, 1886, for the manufacture and sale of telephones, but they wrote to the plaintiff company stating their intention to manufacture and sell the article, which they invited the plaintiffs to inspect at the offices of the company, where it was fitted up. The plaintiffs took no notice of the letter. In December, 1887, and February, 1888, when the plaintiffs found the company was at work, they bought two of the instruments alleged by the defendants to be made according to their patent, and asserted by the plaintiffs to be an infringement of their patent. It was this instrument which it was sought to restrain the manufacture and sale of, and which it was said the defendants were endeavouring to force the plaintiffs to bring another action to try over again the validity of, notwithstanding the judgments already given in its favour. The defendants opposed the present motion on the ground of delay, arguing that as they knew in 1886 what the defendants were doing they ought to have come to the Court sooner. By an affidavit of the manager of the plaintiff company it was sworn that they did not take steps against defendants because it was thought the defendant company was a bubble company, and that the notice was only a threat, but as soon as they found the company was in active operation they brought this action. Mr. Justice Chitty said the plaintiffs were entitled to the injunction they sought, and that there had not been delay on their part. Undertakings in damages were given by both the plaintiffs and defendants.

COMPANIES' MEETINGS & REPORTS.

The German Union Telegraph and Trust Company (Limited).

The seventeenth ordinary general meeting of the shareholders of the German Union Telegraph and Trust Company (Limited) was held at the offices, Winchester House, 50, Old Broad-street, last Monday, under the presidency of Sir James Anderson.

The SECRETARY (Mr. W. Payton) read the notice convening the meeting and the minutes of the ordinary and extraordinary general meetings, hold respectively on the 21st March and 28th November, 1887. The minutes having been approved and signed as correct,

The CHAIRMAN said: When I last addressed you, I told you all that was to be said about the offer of the German Government for the purchase of our cables, and we were authorised to negotiate and carry out the terms of that offer. Notwithstanding what we considered a somewhat favourable offer, there was still a large margin of reserve about which we thought we should like to know more as to its distribution. Having that idea in view, your solicitor, Mr. Burt, your secretary, Mr. Payton, and myself went to Berlin last month, believing that we might possibly be forwarding the shareholders' interests by getting a portion of that reserve for the Company. There was a large sum of about £25,000, but there were important agreements which had to be made, some of them extending over a period of 11 or 12 years, and, naturally, those who had those agreements would have liked to get all they possibly could claim. We, however, thought we might give what was perfectly equitable and fair, and still obtain something out of that large sum for our shareholders. I am happy to say that we succeeded in that—not, of course, without some little warmth and discussion; but we parted good friends with the other side, and we are, we believe, about £10,000 richer than we were before we left here on that mission. We also agreed about the rent of our office at Berlin, the expenses of liquidation, the stamps, and, in fact, about every item that your solicitor or secretary could think of as likely to dip into this reserve; and we can therefore say with some accuracy that we think, if all goes well, we shall pay you within 1s. or 1s. 6d. of par. That will depend naturally on the expenses of repairs and breakages that may happen between now and next year. Our cable is broken just now, and the steamer "Britannia" is on the spot waiting for two or three fine days to effect the repair, which no doubt will be easily done. I do not think I have much more to say. We parted from our Berlin colleagues good friends, and I hope we shall not have to visit that city again on a similar errand. You will get your dividend to-day of 8s. 3d., and there will be no more dividends until next January, when you will, I believe, get three-fourths of your capital back, and the final distribution of capital will be in April. There is a meeting to be held in Berlin on the 27th inst., a final meeting to arrange all about the liquidation and pass the necessary resolutions, but as we were all agreed the other day when we were at Berlin, I hope we shall not have to go there again, but that it should be sufficient that our interests should be represented by our friends there by power of attorney. This is, perhaps, the last meeting but one of the German Union Telegraph and Trust Company. I am very sorry that it is to be wound up, because it is going on very well, but as the Government would not have a private company working the traffic, we had to put up with that decision. It is now my duty to move:—

"*That the report and accounts for the year ended 31st December, 1887, submitted to this meeting be and they are hereby received and adopted, and that a dividend of 8s. 3d. per share be declared payable this day free of income-tax, making, with the previous distribution of 5s. 9d., a total dividend for the year of 14s., or at the rate of £7 per cent. per annum.*"

That is compared with 6 per cent. last year.

Mr. H. G. ERICHSEN seconded the resolution.

The CHAIRMAN: If there are any remarks I shall be glad to answer and questions.

A SHAREHOLDER said he supposed the last dividend would be up to the 31st December, 1888, and that they would get no payment after that.

The CHAIRMAN: This is the last dividend. You will get your return of capital, which will include the dividend, whatever it is, in January and April.

The CHAIRMAN then put the motion in the usual way and declared it carried unanimously. He next proposed the re-election as a Director of Mr. Erichsen.

Mr. LOEWENTHAL seconded the motion.

The CHAIRMAN put the resolution, and it was carried unanimously.

Mr. LOEWENTHAL proposed the re-appointment of Mr. Henry Dever as auditor for the current year, at a remuneration of £25.

The CHAIRMAN put the motion in the usual way, and, having declared it carried unanimously, observed that that was the whole of the business.

Mr. WELLS proposed a vote of thanks to the Chairman and Directors, and said he thought they ought also to thank the Solicitor and the Secretary. Those gentlemen went to Berlin the other day in very inclement weather, and they appeared to have made a most satisfactory arrangement for the Company, by which the shareholders would get a larger sum than they anticipated when the purchase was made by the Government.

Mr. LOEWENTHAL seconded the motion, which was carried unanimously.

The CHAIRMAN: We are much obliged to you, gentlemen. It was not at all an agreeable task we undertook in going to Berlin. We knew that we were going to have something of a combat, and I think all ended very well.

Mr. LOEWENTHAL: The only regret we have is to part with you.

The SOLICITOR: That is a mutual feeling.

The proceedings then terminated.

The Direct Spanish Telegraph Company (Limited).

Report of the Directors for the half year ended 31st December, 1887, to be presented at the general meeting of shareholders, to be held at Winchester House, on Monday, the 26th inst., at twelve o'clock:—

1. The accounts for the half year ended 31st December, 1887, show, after providing for debenture interest and the balance of the charge for

Digitized by Google

renewal of the shore-end of the cable at Marseilles, a balance to the credit of profit and loss of £5,564. 9s. 10d.

2. The traffic receipts are in excess of those for any half year since the formation of the Company, and show an increase of £1,338. 12s. 10d., as compared with the corresponding half year of 1886.

3. This increase of traffic has necessitated only a moderate amount of additional expenditure.

4. The Company's cables, and the land lines in connection with them, have continued in good working order throughout the half-year.

5. The Spanish Government Telegraph Administration, recognising the importance of the cable communication between Spain and England, has erected a new wire, of the most improved type, between Bilbao and Madrid, to be used exclusively for the cable work of this Company, and this will, no doubt, beneficially affect the traffic.

6. After putting £2,500 of the balance of profit and loss to the reserve fund, which now amounts to £8,447. 19s. 1d., there remains £3,064. 9s. 10d. available for dividends. The Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend of 2¾ per cent. (free of income-tax) for the half year upon the ordinary shares, making, with the previous distribution, 4 per cent. for the year 1887, and to carry forward £185. 16s. 8d.

The dividend warrants will be issued on the 3rd of April.

7. Sir James Anderson and Mr. Etlinger are the Directors retiring by rotation, and being eligible offer themselves for re-election.

8. The auditor, Mr. Herbert R. Duke, retires, and offers himself for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The directors of this company announce a dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended 31st December last, payable on the 24th inst. The traffic receipts for the week ended March 16th amounted to £4,979.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The directors of this company announce the numbers of 113 bonds of £100 each of their 5 per cent. debentures (1880 issue) which have been drawn for payment at par on May 1st next.

EASTERN TELEGRAPH COMPANY.—The directors of this company announce the payment on April 14th next of a dividend of 3s. per share on the preference shares, less income tax, for the quarter ending March 31st, 1888, and an interim dividend of 2s. 6d. per share on the ordinary shares, free of income tax, in respect of profits for the quarter ended December 31st, 1887. The register of transfers will be closed from April 6th to 13th, both days inclusive.

THE EXETER ELECTRIC LIGHT COMPANY (LIMITED).—The prospectus has been issued of the Exeter Electric Light Company (Limited), with a capital of £20,000 in 2,000 shares of £10 each, nearly one-half of which is said to be already assured. Mr. Massingham is to be managing director, and Messrs. Laing, Wharton and Down electrical engineers; the secretary and registered offices, Mr. H. W. Michelmore, 16, Cathedral-yard, Exeter.

THE LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—The subscription list for the new issue of capital of this company is now closed. The number of shares applied for very largely exceeds the number that the directors have to issue. It is expected that the allotment letters will be sent out in the course of next week.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 16th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,181.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended March 15th, 1888, amounted to £3,333, as compared with £3,278 for the corresponding period of 1887.

REMOVALS.—We are informed that the registered offices of the National Telephone Company (Limited) will be removed on the 24th inst. to 162A, Queen Victoria-street, E.C., directly opposite St. Paul's station and close to Blackfriars Bridge.

—— Messrs. Thompson, Ritchie and Co., late of Winchester House, Old Broad-street, E.C., inform us that they are removing to more convenient premises, and that on and after the 25th inst. their address will be Connaught Mansions, Victoria-street, Westminster.

—— Messrs. B. and G. Shorthouse (manufacturers of copper wire for telegraph, telephone and all other uses, shaped copper and every requirement in metals for electric light companies, &c.), have removed their London offices to Mansion House-chambers, 11, Queen Victoria-street, E.C. Messrs. Applegarth and Stove, submarine and electrical engineers, are the sole agents.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 515.—Vol. XX. FRIDAY, MARCH 30, 1888. Price 4d.

NOTES.

The proposal to found an Association of Electrical Engineers has cropped up again in a new quarter, if not in an altogether new form. The April number of *Electrical Plant* treats us to a long article on the subject, demonstrating the futility of the original proposal and the highly feasible character of its own. As to the mode of carrying it out, namely, to constitute the Association a special section in the London Chamber of Commerce, we offer no opinion whatever. If it will satisfy the requirements of the trade we shall be quite content to support a scheme taking that shape; and if our contemporary can work it in that direction to the satisfaction of everybody concerned, we shall be as pleased as the rest.

But a "section of the London Chamber of Commerce" is not exactly an association such as our clients in these pages were desirous of forming, nor indeed such a one as *Electrical Plant* seems to be contemplating when setting forth the functions and objects of the proposed Trades Guild. What, however, we are chiefly concerned to notice in this connection is the erroneous description given of our own project, and the causes of its failure. We distinctly avowed the purely trade object of the association, and all along disclaimed any idea of trespassing on the ground of the Society of Telegraph-Engineers, or of any scientific body whatever. The fact may be usefully recalled just now, because if anybody else intends to succeed where we failed (assuming that we did fail) they must be prepared to face obstacles in the trading, not in the scientific, interests affected by the proposition.

We do not ourselves admit that we failed—quite the contrary; we succeeded in gathering all the elements of success together, and if this revival of the idea gets any further, it will be because we have smoothed the way for it. One reason—we need not refer to other reasons why the project went no further was no doubt the changed attitude of the Society of Telegraph-Engineers and Electricians. It was only fair to see what would come of its new designation. Apparently, *Electrical Plant* does not think so. Before the Society has had time even to formally alter its title, this new scheme is sprung upon it, as if the alteration meant nothing and would result in nothing. For our part we prefer to give the Society a fair chance of "living up to" its expressed ideal.

The Schanschieff battery is undoubtedly a very superior battery, and we endorse everything the experts have said about it; but, unfortunately, the public do not read expert evidence very carefully, or they would mark the limitations and qualifications with which that testimony is guarded. Unfortunately, too, the experts are not asked their opinion as to the money value of the article submitted to their examination. Seventy thousand pounds "in cash or shares," and 10,000 shares down of £5 each, is a remarkably stiff price to pay for any battery, "*some of* the qualities" of which are "superior" to those of all other voltaic batteries; and when a company starts to work it with this dead weight round its neck, and a capital of £200,000, its superiority as a marketable commodity becomes very questionable indeed.

It is curious to note in this relation how easily the financial world receives or rejects at pleasure the opinions of scientific experts. One financial organ, which fires a great boom on behalf of the "Schanschieff Electric Light and Power Company," and quotes with triumph the verdict of a very high scientific authority on the Schanschieff battery, contemptuously contrasts it with another kind of battery, which is called "a will-o'-the-wisp of its time"—evidently forgetting that it was launched with similar credentials from the self-same hand.

In our issue of July 1st, 1887, we published the full text of the Admiralty specification for engines and dynamos. With regard to the latter, we offered some criticism at the time upon the extremely rigorous stipulation with regard to the permissible rise of temperature, which was not to exceed 20° F. above the temperature of the atmosphere in any part of the machine. Our opinion of the practical impossibility of fulfilling this requirement was, doubtless, shared even by those firms who tendered for the work. We are glad to know, however, that in the specifications now issued the condition has been modified to the extent of applying the limitation to the armature conductors alone.

In connection with a very important scheme of electrical engineering (which has for some time been in progress, although the particulars have not yet been made public), there has recently come to our knowledge a very unfortunate instance of arbitrary interference on the part of the Board of Trade. Without going further into detail, it will be sufficient to say that the design originally contemplated a potential difference of 1,000 volts, and that it would be difficult to imagine any

Digitized by Google

possible set of conditions under which a high tension could be employed with greater security and propriety. The question of public safety in this particular case simply does not enter into the problem. Nevertheless, the Board of Trade has thought proper to prohibit the use of a difference of potential greater than 250 volts. Since there is at the present time no recognised authority in existence to whose views the Board might be expected to defer, the contractors have nothing for it but to submit. The Society of Telegraph-Engineers and Electricians might possibly be induced to form a "Permissible Difference of Potential Committee," but we fear that in this case the time-constant would be so large that by the time its own differences of potential had been adjusted the matter would have been settled out of court.

IN another column will be found a description of a very remarkable and successful application of electricity to pumping in mines. In connection with this subject several letters have recently appeared in the columns of the engineering press advocating the employment of compressed air and questioning the practicability of electricity. Surely it is now incumbent upon these gentlemen to vindicate their position by figures and hard facts. In comparing the two systems one must bear in mind that the losses in the steam engine, pumps, and rising main are common, and can therefore be neglected as having no vital bearing on the real question. What we have to compare is the loss in dynamo cables and motor, and that in compressors, supply pipes, accumulators, and air engines. The loss in the cable and supply pipes may also be struck out as quantities varying in every case—they affect chiefly the capital outlay. Now, a good dynamo and motor have a joint conversion efficiency of not less than 75 per cent., and under favourable circumstances may rise as high as 82 per cent., or even 84 per cent. But what will the most sanguine partisans of the rival force say about the compressors and air engine? Will they claim 50 per cent. efficiency, and give the figures, as electrical engineers do? Probably, under very favourable circumstances, with low pressures, 50 per cent. might be reached, but with high pressure (such as would be required for 7,000 gallons per hour through 900ft.) without an extravagantly large plant, the efficiency would be probably not more than 25 per cent. at the outside. In addition to this we have the question of prime cost, which is all in favour of electricity.

IT is well known that in all electric power circuits the current is necessarily variable, owing to the changes of load; but even with comparatively constant work, where an ammeter will give practically steady reading, the fluctuations of the current are of great importance. Those makers who have had occasion to build large motors have for the most part been long aware of this fact, and it has been found necessary to increase the cross-section of the cut-outs in such circuits by 50 per cent. to 100 per cent. beyond what would usually be employed for the same average current in lighting circuits. The heating effect is, in fact, that due to the square of the mean current plus half the square of the difference between the maximum and the minimum currents. But this is not all; this large variation causes considerable increase in the heating of the iron of both armature and field, as the result both of hysteresis and of Foucault currents, and the effect will be the more marked as the density of the lines of force increases. In designing large machines this point is of special importance, and attention has to be given both to the arrangement of the iron and to the magnetic density. A case showing the possible magnitude of this heating occured in the Immisch pumping plant at Normanton, already referred to. It was found necessary in this case not to allow the density of the field to exceed 16 Kapp-units (or 15,350 C.-G.-S.) in the dynamo magnets, and 13 Kapp-units (or 12,500 C.-G.-S.) in the motor; the field is also laminated. With these precautions the results are perfectly satisfactory, and the rise in temperature in the motor and dynamo is approximately the same.

MEMBERS of the Society of Telegraph-Engineers and Electricians were provided with an unusual treat last Thursday evening in the beautiful experiments of Prof. RÜCKER and Mr. VERNON BOYS on stress and strain in the dielectric. The success of lecture experiments in which static electricity plays a part is always more or less problematical, and the admirable way in which the experiments "came off" after a little coaxing is a legitimate subject for congratulation. Prof. RÜCKER gave a very lucid account of the phenomena, and we hope to print it in our next issue. Meanwhile, we may remark that M. BLONDLOT has just published a paper on the same subject, in which he describes some experiments undertaken in order to settle an outstanding question, to which Prof. RÜCKER also made reference—namely, whether the effects of double refraction are really due to the setting up of a quasi crystalline structure in the dielectric, or whether they are merely a secondary result due to the mechanical pressure caused by electrostatic attraction. It has been suggested that in the latter case convection in the liquid would account for the observed phenomena. M. BLONDLOT therefore devised an *experimentum crucis* to test the truth of the latter hypothesis. If convection had anything to do with the matter, owing to the inertia of the liquid, some interval would elapse between the establishment of the electrical condition and the appearance of the corresponding optical phenomena. M. BLONDLOT has shown by experimental evidence that if there be any such interval it is certainly less than $\frac{1}{10000}$sec. But, apart from this, since the experiment, though difficult, sometimes succeeds with glass, it does not seem that convection could, under any circumstances, offer a complete explanation.

AFTER Prof. RÜCKER'S lecture, the Society had an opportunity of trying the Robertson Writing Telegraph, a set of instruments having been set up in the lecture room. This instrument—which has already been described in our columns—would undoubtedly have been of much practical importance if its invention had only preceeded that of the telephone.

BUT whilst the Society as Electricians are studying stress and strain in the dielectric, and as Telegraph Engineers are investigating the writing telegraph, the Electrical Engineers are bitterly complaining of the stress and strain due to con-

Digitized by Google

flicting Fire Office Rules. With much that our correspondents have to say we are fully in accord, but we think it a pity—since matters have been allowed to drift into the present state—that a disposition should be shown to reject the good offices of the Society in bringing the question to an issue. That something will have to be done to avert the threatened state of chaos is certain. It is equally undeniable that the parties primarily concerned are the Fire Offices on the one hand and the electrical contractors on the other. But the essence of the difficulty lies in a fact that does not seem to be generally appreciated or understood—namely, that the Fire Offices are very far from working together harmoniously in this matter. Furthermore, it will make little difference to the latter whether any standard rules are or are not agreed upon; but it will make a good deal of difference to the contractors. Since no recognised association exists whose competency to deal with such a question is recognised by all concerned, the best thing for the present is simply to suspend our judgment until after the report of the Society of Telegraph-Engineers' Committee has been made public. This, as we announced last week, will take place at an early meeting of the Society.

FURTHER complaints reach us on the subject of trade catalogue piracy. From Messrs. WALTER T. GLOVER AND CO. we learn that several pages of their price list have been reproduced, word for word, as original matter in the catalogue of another firm who manufacture the same class of goods. A like compliment is sometimes paid to ourselves by the republication—without acknowledgment—of tables and formulæ which first appeared in *The Electrician* and the "Electricians' Directory." The practice is in every way to be deprecated, and our correspondents even suggest that the Society of Telegraph-Engineers and Electricians should take the matter up—at all events, so far as the interests of electrical trades are concerned.

AS an illustration of the improved tone of the gas journals towards the electric light, we note the *Gas World* of last week quoting with approval a speech of Mr. FRANK RIDLON addressed to the New England Association of Gas Managers, in which he predicts that the gas engineers and electrical engineers "are destined to come together in the future as practical engineers" for the public service. Mr. RIDLON is himself an electric light engineer; and the *Gas World* praises the friendly feeling which inspired his words on the occasion referred to, adding an opinion of its own that it would be an agreeable change at the Gas Institute if a recognised authority on electric lighting were occasionally heard at its meetings. It would be a change, no doubt, and we hasten to say that it would be one quite agreeable to us.

AT the meeting of the Maxim-Weston Company, held yesterday, and reported in another column, it will be seen that Mr. HUGH WATT, M.P., entered into a detailed explanation of the position of the Company. He stated that the reason for the non-payment of a dividend this year was that three important contracts had fallen through, causing a decrease in the profits, compared with those of the previous year, to the extent of £3,000. Perhaps, the most remarkable feature of the long and animated discussion which followed was the speech of Mr. LOUIS SWABY (a director of the company), in which he maintained that the balance-sheet was a farce, and disclaimed any responsibility for it. After the adoption of the report and accounts, a committee of five shareholders was appointed to confer with the directors on the affairs of the company, and the meeting was adjourned for four weeks.

The Forbes Meter.—It is stated that the Westinghouse Electric Lighting Company has adopted Prof. Forbes' current meter.

Obituary.—Mr. Edward Dwyer Gray, M.P., who was chairman of the Telephone Company of Ireland, died at his residence, Dublin, on Tuesday night.

American Competition.—According to the *Financial Times* "large orders of electric light machinery are being shipped from New York to Europe and Great Britain."

Lighting of Railway Stations in France.—The Chemin de fer du Nord are about to light several of their provincial stations by electricity, and the lighting of the St. Denis station will be extended.

Spanish Tenders for Telephone Service.—The *Madrid Gazette* of the 23rd March contains a Royal order for tenders to be invited for the establishment and working of a telephone service in the manufacturing town of Alcoy, Province of Alicante.

The Lighting of H.M.S. "Nile."—The magnificent ironclad the "Nile," which was launched from Pembroke Dockyard on Tuesday, is lit throughout by 500 incandescents, and carries four powerful search lights. The current is supplied from three dynamos, each capable of giving 400 amperes.

Electric Light at Falcon Cliff, Isle of Man.—Messrs. C. L. Baker and Co. (Limited), of the Cornbrook Telegraph Works, Manchester, are engaged in fitting up Falcon Cliff Hotel, pavilion and grounds with the electric light. The installation will consist of ten arc lights of 2,000 candle-power, and over 400 incandescent lights.

Taunton.—The organ at St. John's Church, Taunton, is to be blown by electricity. The posts to carry the wires have been placed across the lower end of the Crescent-field, and the work is to be finished in about a week. It has created much interest in the town, and is being carried out by the Taunton Electric Light Company.

The New York "Electrical Review."—The prosperity of electrical business, and consequently of electrical journalism, in the United States is indicated by the enlargement and improved appearance of such papers as the New York *Electrical Review*, which this month starts a new series with an artistically designed wrapper and a wider range of contents.

Alleged Electrical Fire at Lucerne.—An hotel was last week burnt down at Lucerne, and a statement appeared in the local papers, and has been reproduced in this country, alleging that the fire was caused by the electric light fittings. We have, however, received a telegram from Messrs. Ganz and Co., of Buda-Pesth, contradicting that statement.

The City Guilds Institute.—From a copy of the *Journal* of this Institute for the month of February we observe that the old students' *Journal* has been incorporated with it, and that the contents are more varied and interesting than ever. We are pleased to see this evidence of *esprit de corps* among the students and staff of the Finsbury, Kennington, and Kensington Colleges.

Fire Alarms.—The Watch Committee of Stockport invite tenders to provide and erect fire alarm signals, consisting of electric bells and telephone. Particulars can be obtained of Superintendent Buck, Police Office, Stockport, and tenders must be endorsed "Tender for Fire Alarms," and be delivered to Mr. W. Hyde, town clerk, by 10 a.m. on the 6th of April.

A Mistake.—At Pittsburgh recently a company working an electric tramway on the conduit system had a large quantity of salt sprinkled on the line in order to melt the snow. As the conduit was made of wood, and the potential difference was 500 volts, the result can easily be imagined. The melted salt and snow soon bridged across the conductors, and the woodwork was set on fire.

The Electro-Harmonic Society.—The last smoking concert of this society for the present season will be held on Friday, April 6th, at the St. James's Hall Restaurant (banquet room), to commence at eight o'clock. A capital programme has been arranged, including a violin duet by MM. Jacques Greebe and T. E. Gatehouse, and some readings by Mr. Charles Fry. Musical directors, Mr. T. E. Gatehouse and Mr. Arthur Thompson.

Cold Soldering for Copper Wires.—In the *Elec. Tech. Zeits.*, Berlin, Herr Muller, of the Telegraph Service, suggests the use of cold soldering for hard-drawn copper and bronze wires, so as to avoid softening the wires by heat. He prepares his solder by heating precipitated copper made in a stream of hydrogen. The reduced copper when quite cool is rubbed in a mortar with mercury and very weak sulphuric acid, and then well washed.

A Source of Error in the Quadrant Electrometer.—M. Hallwachs has pointed out that in the quadrant electrometer a source of error may sometimes exist owing to the differences of potential between the various metallic parts of the instrument which are insulated from one another. This error may, of course, be minimised if the precaution is taken of "earthing" every part of the apparatus immediately before making an observation. It is also evident that in the case of alternating currents the error from this cause does not occur.

The Irish Exhibition in London.—We are extremely glad to notice that the arrangements are now completed for this interesting exhibition of Irish art, industry, and trade during the coming summer. It will be held in Olympia, Kensington, and is expected to be open from June 4 to October 27. The object is a most praiseworthy one, and being entirely outside politics it has secured the support of a remarkably numerous and powerful body of patrons. The usual rules relating to patent exhibits will apply, the exhibition being certified as an international one by the Board of Trade.

United Cables v. Truro F.C.—This match was played on Saturday last (24th) at Penzance during a heavy snowstorm. The United Cables won by three goals to one, which were obtained by Messrs. Walton, M'Lean and W. Raymond. The United Cables have only played four matches this season and have won them all. Team as follows :—M'Lean and Walton, right wing; Henderson and Mackenzie, left wing; Raymond and Adson, centre; Leahy and Davies, half-backs; Mathews and Palmer, backs; Thorngate, goal. All are Exiles with the exception of Adson and Walton, who have, nevertheless, rendered good service on every occasion.

Royal Institution.—The following are the lecture arrangements after Easter :—Dr. Charles Waldstein, three lectures on John Ruskin; Mr. Walter Gardiner, three lectures on The Plant in the War of Nature; Mr. Sidney Colvin, three lectures on Conventions and Conventionality in Art; Prof. Dewar, six lectures on The Chemical Arts; Prof. T. G. Bonney, three lectures on The Growth and Sculpture of the Alps; Mr. Carl Armbruster, seven lectures on The Later Works of Richard Wagner (with vocal and instrumental illustrations); Prof. C. E. Turner, three lectures on Count Tolstoi as Novelist and Thinker. The following are the probable arrangements for the Friday evening meetings after Easter :—Prof. Flower, The Pygmy Races of Men; the Right Hon. Sir William R. Grove, Antagonism; Mr. James Wimshurst, Electrical Influence Machines; Prof. J. K. Laughton, The Invincible Armada: a Tercentenary Retrospect; Mr. W. H. Barlow, Building the New Tay Bridge; Mr. Francis Galton, Personal Identification and Description; Prof. J. A. Ewing, Earthquakes and How to Measure Them; and a discourse by Prof. Dewar.

Telegraphic Communication.—In the House of Commons on Tuesday last, in answer to Mr. Causton, Mr. Raikes said: In reply to the hon. member, I have to say that I have no official information of the inconvenience and loss which have resulted from the breakdown of telegraphic communication in New York, but I understand that the breakdown was caused by a snowstorm, which damaged the wires. About 50 per cent. of the telegrams of the United Kingdom pass through the central telegraph office in St. Martin's-le Grand. Only on the top floor of that building are the fire hydrants not supplied from the street mains; they are supplied from tanks on the roof containing 28,000 gallons of water pumped up from the artesian well on the premises. It is not true that the building was in any danger from a fire in Paternoster-row. The present arrangements have been made after mature consideration, and there is no intention to establish a duplicate central telegraph office. The building, I may add, is fireproof throughout.

Electric Traction on the Brussels Tramway.—We regret to observe that the experiments which have been carried out on the Brussels tramways in electric traction by means of the Julien accumulator have not led to results of a satisfactory character. The report of the directors of the Tramway Company, which was presented at a recent meeting of the shareholders, contained the following passage :—"Yielding to a desire manifested, or rather to a requirement formally expressed, at the general meeting held on March 15th, 1885, by an important group of shareholders, we have made trials with electric traction. Hitherto, these experiments have not responded to the expectation of the promoters. The first car commenced to run on the 17th April [1887], in the Rue de Belliard and the Place Royale, a second was added on the 8th May, and a third on the 17th September. The electric cars during 1887 ran a total distance of 54,987 kilometres, representing 4,800 horse journeys. We are still endeavouring to improve the economical conditions, particularly as regards the cost of maintenance of the apparatus [? the batteries]. Until this has been accomplished we do not see our way to augment the number of cars in use."

Douglas, Isle of Man.—On Thursday last a public meeting was held in Douglas, in order to consider the question of forming a company to provide the town with electric light. Mr. Alexander Siemens addressed the meeting, and gave facts and figures in connection with the more important installations carried out during the last few years by his firm. To light the Promenade with eight arcs ought to cost 6d. per lamp per hour, or 16s. a night, say £100 for the season. The company would be able to make a profit by supplying current to private houses at the rate of ½d. per lamp

Digitized by Google

hour. The following resolution was carried unanimously :—"That in the opinion of this meeting it would be to the advantage of the town of Douglas if a system of electric lighting from a central station were established without delay, and the meeting will do all in its power to further the taking up of the shares in the Electric Lighting Company." After the meeting a conference took place between Mr. Siemens and others interested in the formation of the company and the Douglas Town Commissioners. Mr. Siemens laid before them a definite proposal with reference to lighting the Promenade with the electric light, but the members present decided that they could not entertain the proposal until the company was floated.

Electric Lighting on Steam Yacht "Wanderer."—This magnificent vessel, owned by Prince Tartonia, of Rome, has just been fitted with a very elaborate installation of electric light by Messrs. Muir, Mavor and Coulson, of Glasgow. The plant consists of the following :—A steam boiler built on a modification of Cole's patent, designed to give 12 indicated horse-power, at 80lb. pressure; a Willans compound central valve two-crank engine, mounted on the same bed-plate with and coupled direct to the dynamo, which is driven at 445 revolutions per minute (the engine is fitted with light feed lubricator tachometer and Willans governor); a dynamo with a maximum output of 10,000 watts, giving an E.M.F. of 75 volts as a simple shunt for charging batteries, and 60 volts as compound for running the lamps direct; a complete auxiliary condensing plant, consisting of a copper condenser and a set of circulating air and feed pumps mounted on the same bed-plate with and driven through worm gearing by a special double acting high-speed vertical engine; an accumulator with a capacity of 630 ampere hours, the plates of which are in teak wood boxes, which are carried on massive racks and rigidly secured by wedges. The space available for fixing the above plant is admirably suited to the purpose, being two large cabins on the main deck, abreast of the engine room, with doors opening to the middle platform. Steam connections are provided from both the main boilers and the auxiliary boiler; the engine has also three alternative exhausts: 1st. To the main condenser, for use while at sea and steaming, from the main boilers; 2nd. To the auxiliary condenser above mentioned, for use while in port; and 3rd. Through a non-return valve to the atmosphere under the water line. The hot water from the auxiliary hot well may be delivered to either or both the main boilers, or to the auxiliary boiler. The drains may be directed to the bilge or the auxiliary condenser. The main conductors from the dynamo are brought to a handsomely-fitted switch-box with instruments mounted, affording very complete control of the circuits and accumulator. A search light of 2,000 candle-power is fitted on the navigating bridge, and a gangway lamp of 200 candle-power in a large lantern is suspended over the ship's side from a special davit. The fittings throughout are of very handsome pattern, and the wiring has been carried out with special reference to neatness and security. The mains are brought to double-pole fuse boxes, with slate bases where the fuses are centralised, and the branch wires led away in grooved casings of maple or Hungarian ash, with polished covers. The contractors have spared no trouble in their efforts to make this one of the most complete sets of apparatus afloat.

The Equitable Telephone Association versus the United Telephone Company.—The following circular has been issued by the Equitable Telephone Association :—

"The United Telephone Company having commenced proceedings for infringement, which they are advertising in the public press, against the Equitable Telephone Association, and having obtained against the latter association an interim injunction, which they are also advertising, pending the trial of the action, which trial cannot come on for some months, the Equitable Telephone Association think it right to justify the conduct of their past business.

"The association was incorporated as long ago as the 15th December, 1886, and although advised by eminent counsel that the instruments intended to be used by the association were not infringements of the patents held by the United Telephone Company, yet the directors of the association thought it right, having been informed of the pretensions of the United Telephone Company to a monopoly of the telephone business of the country, before commencing to supply instruments, to challenge the United Company to attack such instruments, with the hope and intention that the challenge would be accepted, and the litigation, which was then considered inevitable, terminated before the association commenced to supply telephones to the public.

"With this view the following letter was addressed by the solicitors of the association in February, 1887, to the United Company, giving express notice of the intention to manufacture and sell telephonic apparatus under Mr. Swinton's patent, and challenging the United Company to attack, if they dared do so, the instruments proposed to be manufactured and sold :—

'40 and 42, Queen Victoria-street, E.C.,
'February 25, 1887.

'DEAR SIR: We are instructed by the Equitable Telephone Association to inform you that the association is about to manufacture and sell telephonic apparatus, the transmitter of which is constructed under the various patents of Mr. A. A. Campbell Swinton, whose patent rights the company has purchased.

'In order to give you an opportunity of inspecting the instruments, a set has been fitted up at these offices, and we are prepared to arrange an appointment to produce them for the inspection of yourself and your company's electricians.

'We should add that the company is advised by eminent counsel that the instruments are in no way infringements of the patents held by your company, but knowing the extent of the claims made by your company—ill founded claims, we believe—to altogether prevent the use of any electric transmitters in which carbon is used, the board of directors of our company think it right to give your company distinct notice of the intentions of the association with a view to challenging your company to contest the right of our company to manufacture, use, and sell the instruments in question, should your company after inspection think fit so to do, a contest which our directors will enter into with the full assurance they will succeed in maintaining the instruments it is the object of the association to deal with.

'Yours faithfully,
'DAVIDSON AND MORRISS.'

"To this challenge the United Company did not respond, and until the 9th of the present month of March, when a writ was issued without any previous warning or notice by the United Company against the association, no objection was made by the United Company to the business the association was transacting. The writ was followed by a motion for injunction, which was heard on Friday, 16th March, when an interim injunction was granted, restraining the association in the usual terms from dealing with telephonic instruments, the United Company giving the usual undertaking to be answerable in damages caused to the association.

"Owing to the short time at their disposal, the association was practically precluded from producing any scientific evidence on the hearing of the above motion, and their defence, therefore, rested solely on the question of there having been undue delay on the part of the United Company.

"The association have every intention of contesting the action to the utmost of their ability, and they will press the case on as far as lies in their power, with a view to as early a trial as practicable.

"They believe that they have a complete defence, and they have every confidence that they will be able to uphold the complete freedom of their instruments."

HIGH-RESISTANCE METALS AND ALLOYS.

BY W. M. MORDEY.

There are two principal purposes for which resistances are largely used in heavy electrical engineering, in connection with which it is important that the heat generated by the current should not seriously increase the resistance. The first is the ordinary testing of dynamos, where it is necessary to dissipate the energy easily, and where the use of arc or incandescent lamps or of water resistances is inconvenient or expensive. By using wires of known resistance, the temperature coefficient being low, the operation of taking routine measurements is simplified. It may suffice to measure the current only, the potential difference being estimated within one or two per cent. from the resistance of the circuit measured cold, and from the assumed temperature. In the case of dynamos of 2,000 to 3,000 volts, like the large Brush machines, such a test is convenient when machines are being made in quantity.

Whether for such comparatively coarse measurements, or for work requiring greater accuracy, resistances of fixed or nearly fixed value are of great assistance. It is possible, by using very large coils and by providing abundant means of cooling, to keep the actual temperature of the wires down to any required point; but in practice this is inconvenient, and it is therefore very necessary to ascertain what is the best material to use when constructing resistances for such purposes.

COMPARATIVE TEST OF WIRES OF VARIOUS METALS.

All wires of 1 foot long, ·001 section.

The other purpose to which allusion was made is the construction of resistance coils for placing in series with arc lamps supplied from constant pressure mains. In such cases it may happen that an arc lamp when switched on will not strike its arc promptly, thus allowing an excessive current to pass through the resistance, which if of an unsuitable metal will rise so much in value that it absorbs considerably more than is desirable of the available pressure, so that when the arc is formed its potential difference may be too small, resulting perhaps in extinction and a repetition of the objectionable action. Such a rise of resistance may, of course, sometimes be of actual advantage in preventing the passage of very large currents; but it should not be necessary to have to rely upon a resistance for this. A simple calculation will enable any one to see that the conditions which on a parallel system are most likely to result in a steady light are best obtained by using a resistance whose value does not alter with the current.

By the kindness of the Brush Corporation, the writer was able to carry out a few experiments on the metals and alloys named below.

The resistance measurements (*see* Table) were for the most part carried out for the writer by Mr. Money, an assistant in the works of the Corporation, on such wires as came to hand. In all cases these wires were of sufficient length to be very readily measured by a Wheatstone bridge, using a Thomson reflecting galvanometer. They were coiled on small frames of wood, and placed in an oil bath which was heated by a Bunsen burner (the oil being stirred so as to assure an even temperature throughout the bath). As no current traversed the wires except that used for the measurement, the temperature of the wires was always that of the oil in which they were immersed.

From the resistances so obtained the diameter, as measured by a micrometer gauge, and the length, the values given in the table were calculated.

Taking as unity the resistance of the copper—which was of the quality now generally obtainable for dynamo work—we have the following comparative values:—

Copper	1·	Piano steel	16·
Soft iron	5·27	Platinoid	20·
Brass (hard drawn)	6·05	Arsenical copper	28·5
German silver	8·83	Hadfield's manganese steel	37·1

From the table the following values are obtained for temperature coefficients for the range of the experiments, which is sufficient to cover what may be called ordinary working temperature, even for purposes where a good deal of heating is admissible:—

VARIATION PER 1° CENT.

Platinoid	·044	Hadfield's manganese steel	·229
Arsenical copper	·061	Copper	·396
German silver	·080	Piano steel	·517
Brass (hard drawn)	·164	Soft iron	·691

A prominent place in the last list is occupied by arsenical copper, an alloy having the appearance of copper, to which the writer's attention was drawn by Mr. J. Raworth, who had noticed its freedom from variation at a time when German silver was generally regarded as the alloy having the lowest temperature coefficient. It was to ascertain definitely this coefficient, and to find the other properties of the alloy, that these experiments were commenced, the other metals being examined afterwards for comparative purposes. From an electrical point of view arsenical copper is a very interesting, but not altogether satisfactory alloy. It was introduced some years ago for resistance coils, but so far as the writer is aware never seems to have attracted the attention it undoubtedly deserved. The few samples tried showed inequalities both in the specific resistance and in the temperature coefficient. As to its composition no information is at hand, but its very high specific resistance—about three times that of German silver and 28·3 times that of copper, one sample giving a still higher result—and its low-temperature coefficient should make it suitable for resistance coils for bridges, &c., if equality can be relied on. It is, however, not a very satisfactory material for coils for large currents, as when an open coil of it is much heated in the air its surface becomes blackened; and under conditions which do not permanently injure some of the other metals, it is seen to "sweat," and even to give off slight fumes. After being heated in this way its resistance is permanently increased, no doubt by a slight decrease in the diameter of the wire. Another objection to its use where excessive heating is to be expected is its want of rigidity. Like copper, when wound in an open coil or helix and suspended, arsenical copper wire droops very much when heated, so that the lower turns of the helix almost

Digitized by Google

or quite touch one another, and there is no very marked recovery on cooling. Perhaps, however, improvements may be made in this material which will bring it into competition with platinoid. At present, although possessing in a remarkable degree some of the qualities demanded by electricians, particularly a very high specific resistance, it cannot be stongly recommended.

With regard to platinoid, the figures obtained are in accord with results already published. It should be borne in mind, however, that in this case, as in the others, the "temperature coefficient" depends, to some extent, on the range of temperature employed in the experiments. The variation is a curve, and not a straight line, rising more rapidly as the temperature increases; thus by taking a small range at a low temperature the coefficient obtained is more favourable to constancy than if a greater range is taken. The former is allowable where only ordinary atmospheric variations are in question; but for real "heating," such a coefficient does not hold good. Nothing more need be said of platinoid; this material is already well known. While not as high in specific resistance as others, its other good qualities more than make up for the deficiency. The German silver and brass samples present nothing of special interest. The piano steel was found very high in specific resistance, but still higher was Hadfield's manganese steel. The direct relation between magnetisibility and conductivity, which was pointed out some years ago by Prof. Hughes, is here amply illustrated. Manganese steel is practically non-magnetic, and has a resistance about 37 times that of copper, and about six times that of iron, a very pure, soft sample of which was tried.

There is another use to which metals of high specific resistance will probably be largely applied in the future, namely, for the construction of those parts of dynamos, particularly of alternate-current dynamos, where strength is required in combination with high magnetic and electric resistance. For non-magnetic supports, for the ends of armature coils, for hubs of alternate-current machines, and for many purposes which will readily occur to the reader, there is felt at present a need for a good and inexpensive material. For these purposes German silver has been used in the past, but it is expensive, and castings are not always very satisfactory. Besides, its quality is variable, the term "German silver" (like "brass") being a rather loose one. The material which more than any other appears to hold out a promise of being useful is Hadfield's steel. Its strength is very great, magnetically it is as good—or as bad—as brass, while its resistance is the highest of any, so that losses from eddy currents will be small. Further, although its temperature coefficient is high enough to disqualify it for resistance frames, this very property is in its favour for fittings and supports. Unfortunately there is at present one very great objection to it—it is so hard that it is impossible to work it. It is to be hoped that Messrs. Hadfield, who have shown so much enterprise in bringing this steel forward, will be enabled to overcome the difficulties which stand in the way of its employment by electric engineers.

PUMPING IN MINES BY ELECTRICITY.

Some four months ago *The Electrician* contained descriptions of two pumping plants in which the energy was transmitted from the surface to the pit bottom by electricity. The motor and dynamo for one of these were made by Messrs. Immisch and Co., of Kentish Town, London, and the work was carried out under their superintendence. The other was designed and erected by Mr. Brain, of the Trafalgar Colliery.

Both of these installations are interesting as practical successes; but, in point of size, both are insignificant beside another pumping plant which Messrs. Immisch and Co. have now laid down at Messrs. Locke and Co.'s, St. John's Colliery, Normanton.

This new plant is designed to cope with a salt-water feeder of 5,100 gallons per hour, at a vertical depth of nearly 900ft. below the surface. It was decided to raise the water at one lift, and at a rate of about 7,200 gallons per hour, so that the pumps could stand, if necessary, for six hours out of the twenty-four. Since the pressure on the ram faces is about 400lb. per square inch, specially-designed pumps were required, and the electrical plant had to be designed to suit the given conditions. The pumps are differential, with two 6in. and two 4½in. rams, and when doing full duty they run at twenty-five revolutions per minute. It was found, by a preliminary trial of a smaller plant, that the load on the rams varied largely at different parts of the stroke. To avoid the heating that would be entailed in an ordinary motor working under a large current with a regular and rapid variation in its intensity, it was necessary to specially design the field and armature. Messrs. Immisch and Co. have successfully met the difficulty, and the plant has now been raising about 125,000 gallons per day for the last month. To give some idea of the electric problem we may say that the current averages 66 amperes, as read by a Siemens dynamometer, but varies at least 10 amperes on either side of the mean value. It is well understood that the heating effect of a varying current is not proportional to the square of the mean current, but is equal to that plus half the square of the variable part. But, in addition to this, the rapid variations of current increase largely the heating effects due to hysteresis and Foucault currents.

The tension on the dynamo terminals is 600 volts, on the motor 575 volts. The actual power spent on the water, at the rate of 120 gallons per minute through 900 feet, is 33 horse-power nearly. The output of the dynamo is 53 horse-power. Hence the efficiency between the actual useful work and the output of the dynamo is $\frac{33}{53} = 62$ per cent. approximately. The commercial efficiency or ratio of useful work to belt power in dynamo cannot yet be stated accurately, owing to slip in the dynamo belt. However, taking the efficiency of conversion of the dynamo at the low estimate of 85 per cent., the commercial efficiency is not less than $\frac{33}{62 \cdot 5} = 50$ per cent. approximately.

It must be remembered that this efficiency includes all the losses in transmission, viz., that in the dynamo, leads, motor, gearing, pumps, and rising main pipes. In this particular case about 2·5 horse-power is lost in the cables, and some 13 horse-power is absorbed by the gearing and pumps, and by friction of the water in the pipes. It is shortly intended to make a more complete test. Then indicator diagrams will be taken of the engines and pumps, and the various losses will be determined very exactly. But returning to our 50 per cent. conversion between the measured quantity of water and the brake engine power, could compressed air give such a return? The writer, from his experience in this class of work, believes that compressed air would not give a return of more than 20 per cent. of the brake engine power. At any rate, it is curious that not one of the advocates of pneumatic transmission will publish a test of his plant. The writer has spoken to several mining engineers who have carefully measured the water delivered and indicated their engines, with results varying from 15 per cent. to 25 per cent., and this latter under most favourable circumstances.

Another important point of comparison lies in the prime cost of the plant. Omitting again the factors common to both systems, we have first a leading and return cable to set off against the pressure pipes. In most cases, the writer takes it, the cables will cost both less than the pipes, and will be far cheaper to erect. A double cable to transmit 50 horse-power was run by Messrs. Immisch and Co. down a shaft 300 yards deep in seven hours. The dynamo and motor will be found also to cost less than the compressors, accumulators, and air engine to do the same work. The former cost something like 25 per cent. less than the latter.

The question of prime cost is an important one; but, perhaps, that of maintenance and security of running is more important still, in cases where breakdowns may entail very serious consequences. With electricity the cost of maintenance is practically limited to the wear of brushes, commutators, and bearings.

Of course, electrical plant requires to be properly designed

Digitized by Google

for its work and to be well laid down. But the majority of accidents that are likely to happen to such plant can be readily and quickly repaired, and compare very favourably with the ugly breakdowns that occur with machines containing reciprocating parts; indeed, if a proper method of management and daily testing of the system be made, a really serious breakdown is a very unlikely thing, for a fault is easily detected and made good before damage is done. With compressed air plant there is not so much a risk of a bad breakdown as a continual fettling up of the brasses, crank pins, cotters, valves, valve seats, glands, &c. The number of wearing parts is so numerous and the strains so various that it is not to be wondered that the cost of maintenance is comparatively heavy.

In conclusion, it may be mentioned that the motor weighs about 3½ tons, and the dynamo nearly 4 tons. The machines are much heavier than the ordinary Immisch type for traction purposes, in which every 70lb. of dead weight gives approximately a brake horse-power. But here weight did not enter into the question so much as slow speed and cool running. They are working well within the limits of their design, and are capable of doing 50 per cent. more work if necessary. The armatures, 24in. in diameter and 16in. long, are of the cylinder type, with massive commutators and substantial brushes and holders. The motor is wound according to the well-known plan adopted by this firm, in which the coil at the neutral point is short-circuited, and to this is mainly attributed the fact that they run practically sparkless, with a constant lead, although the load is varying 30 per cent. during every revolution of the pump. Electricians will appreciate what this means. The speed of both dynamo and motor is 450 revolutions per minute. The engine is a compound semi-fixed, by Messrs. Robey and Co., of Lincoln, of thirty horse-power nominal, and works at a boiler pressure of 140lb. per square inch.

That the plant is a success may be judged from the fact that Messrs. Locke and Co. have given an order for two new machines of the same power. The new plant will be used to work an endless rope on an engine plane by day, and will be ready for pumping at night if required. This electrical plant is by far the largest at present running at a coal mine, but it may be confidently expected that it will not long remain singular in this respect.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER VIII.—*The Calibration of Current Indicators.*

(Continued from page 544.)

97. *The Tangent Galvanometer as a Standard Instrument of Comparison.*—By a standard instrument is meant one in which the deflections of the needle are directly proportional to the currents passed through the coil, or one in which the current is proportional to some known function of the angle of deflection. This latter condition presents itself in the well-known *tangent galvanometer*, in which instrument the currents passing through the coil are proportional to the tangents of the angles of deflection of the needle. The reason for this action will be fully explained in the chapter on galvanometers, but it may be stated here that in order that an instrument may read tangentially the magnetic field of force produced by the current must be uniform throughout the full range of movement of the needle. To ensure this the needle is made very short in length, not more than one-tenth the diameter of the coil. The coil itself is generally made circular in shape, though not necessarily so; and the needle is pivoted or suspended horizontally at its centre. One of these instruments is shown in Fig. 56. The coil frame C C is circular, and the small needle hangs by a single silk fibre in the centre of the coil, immediately above a graduated dial, D D. The needle is carried in a little stirrup of aluminium, to which a long, fine glass pointer is attached at right angles to the needle. The two ends of this pointer move over the scale divisions on D D, which are marked out in degrees of arc on one side of the coil, and in divisions proportional to the tangents of those degrees on the other side. Hence readings can be taken over either scale by reading from either end of the pointer, and if the tangent divisions are read the deflections are directly proportional to the strength of current—that is to say, if the readings so taken and their corresponding currents were plotted together we should have a

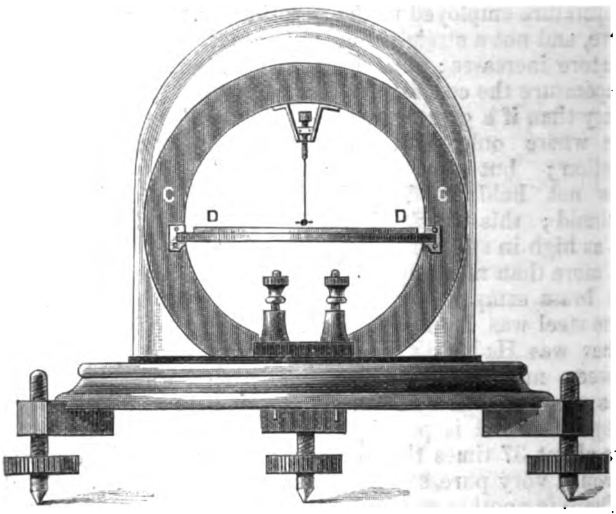

FIG. 56.

straight line, showing them to be absolutely proportional to each other. If, however, the *angles* of deflection are read off and plotted with the corresponding currents producing them, we should have a true tangent curve exhibited. It may be of interest to show this curve and the method of constructing it.

98. *Graphic Method of Constructing a Tangent Curve.*—In Fig 57 the needle of a tangent galvanometer is shown at $n\ s$, with

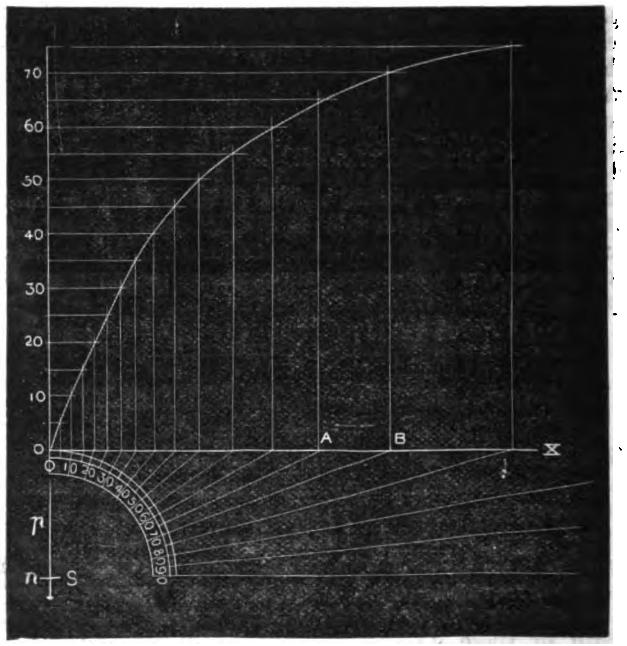

FIG. 57.

its pointer, p, attached to it at right angles. When there is no current passing through the instrument, the pointer will be at zero, and the needle will lie in the same plane as the coil (not shown). Now, when currents of varying strengths are passed through the coil the needle will be deflected, carrying with it the pointer, which moves over a scale graduated in degrees, from which the angles of deflection can be read off.

Now, the currents are not proportional to these angles of deflection, but to their tangents; that is, a current causing a deflection of, say, 60 degrees would not be twice the strength of current causing 30 degrees deflection, but the current strengths would be in the proportion of tan 60 to tan 30. Graphically, we may represent these tangents by distances along the line O X, by drawing lines from the centre of the needle to the various angles on the scale, and producing them till they cut the line O X; the distances from O are then proportional to the tangents of the corresponding angles. For, example, taking the two angles 65 degrees and 70 degrees, the respective distances O A and O B are proportional to the tangents of these angles, and so on for every other angle. For calling the distance from O to the centre of the needle the radius of the arc, we have the actual tangents of the angles moved through by the pointer p (and therefore by the needle, since it is fixed to the pointer), equal to their respective distances along O X divided by the radius; thus,

$$\tan 65^\circ = \frac{O\,A}{\text{radius}},$$

$$\text{and } \tan 70^\circ = \frac{O\,B}{\text{radius}},$$

and so on for all angles. Now, since the radius is common to all, it is evident that distances along O X simply are proportional to the tangents of the angles.

Hence the points on the line O X, found by lines drawn from the centre of the needle through the angles to the horizontal line O X indicate by their distance from the point O the magnitude of the tangents of those respective angles. But the currents are also proportional to the tangents of the angles; therefore the distances from O along O X are proportional to the currents which would cause the corresponding angles of deflection, and we may therefore regard the line O X as marked off in strengths of current, proportional to the currents required to produce those angles of deflection. Now, if we mark off a vertical scale of degrees from the point O, the points on the tangent curve may be found in the following manner:—Lines drawn vertically from the current divisions on the horizontal ordinate must each intersect a horizontal line drawn from its respective angle on the vertical ordinates, and the points of intersection so obtained are actual points on the tangent curve. Thus, where the perpendicular from A cuts the horizontal from 65 degrees, the point of intersection is one point on the tangent curve. Now, on joining together all these points of intersection, the tangent curve is obtained as shown in the figure. This is, of course, precisely the same thing as a calibration curve of any tangent galvanometer, and it will be of interest to compare the shape of this curve with the preceding actual curves which have been plotted for various indicators not constructed tangentially. For instance, the curve in Fig. 52 is of the same general shape as the tangent curve, while the others in Figs. 48 and 53 are of a different type. A curve may, however, greatly resemble, and yet not accurately be, a tangent curve. It will be noticed that the tangent curve is straight along its first portion from O to about 25 degrees, which means that the angular deflections on a tangent galvanometer are directly proportional to the currents producing them up as far as 25 degrees, beyond which the currents are proportional to the tangents of the angles. And it will also be noticed that as the currents are increased the increase of angular deflection becomes less and less, and that a deflection of 90 degrees could never be produced, since this would require an infinite strength of current. Graphically this last fact would be evident by continuing the drawing of the curve in the same way as shown above, when it would be seen that the curve could never reach the height corresponding to 90 degrees, however far it was produced.

99. *Calibration of an Indicator by Comparison with a Tangent Galvanometer of similar Sensitiveness.*—The current indicator to be calibrated is connected in series to the tangent instrument, an adjustable resistance box, and a few cells. Now, since we have a standard instrument in circuit from whose indications we know at once the ratios of the strengths of current flowing, it is not necessary to know the E.M.F. of the battery used, nor to have any idea of its internal resistance; nor do we require to know the values of the resistances unplugged in the resistance box, as in the previous method (para. 87). In fact, instead of using a resistance box at all, we may improvise a water-resistance in the following way: a piece of glass tubing fixed vertically is corked and sealed at each end after nearly filling with water. Two rigid pieces of copper, brass, or iron wire are pierced through the two corks to form contacts with the water; whatever metal is used, it must be the same for each contact, or an E.M.F. would be set up. The lower contact may be very short and sealed up with wax, as it never need be moved, but the top contact wire must be as long as the tube to allow of its moving up and down, and so to alter the water-resistance between the two wires, or the same thing is very conveniently done [Prof. Ayrton in "Practical Electricity"] by having two plates of zinc placed side by side in a vessel in which is a small quantity of zinc sulphate solution, the resistance between the two plates being altered by increasing or diminishing the distance between their lower edges in the solution. The readings for the curve will then be taken on each instrument for every change in the current, starting with no resistance and adjusting the number of cells to give conveniently large deflections of about 80 degrees on each instrument, and then increasing the resistance step by step, noting the angular deflections on both instruments corresponding to each change.

(*To be continued.*)

PATERSON AND COOPER'S DYNAMO.

We illustrate below two of Messrs. Paterson and Cooper's latest designs of "Phœnix" dynamos. In Fig. 1 the magnet

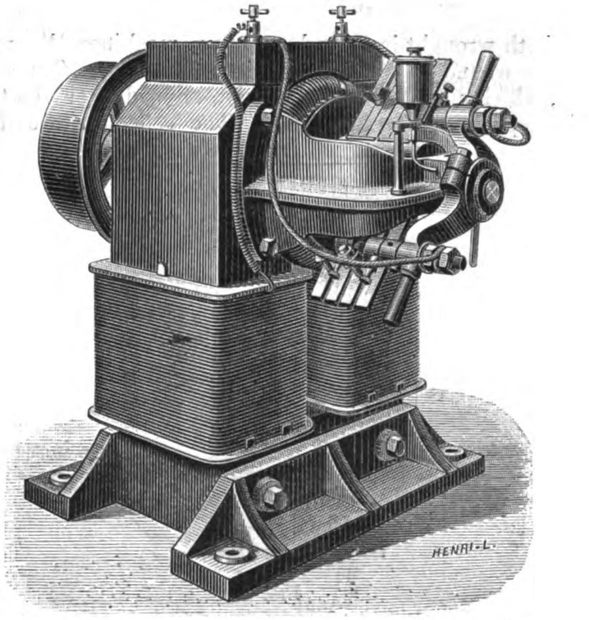

FIG. 1.

consists of a solid wrought-iron horseshoe forging, machined all over and bored out for the armature. Two cast-iron angle pieces are bolted one on each side of the yoke, to form the foundation plate of the machine and to take the holding-down bolts. The armature is supported by strong gunmetal brackets bolted to the magnets, as shown. Without sacrificing stability, it is obvious that this construction ensures a machine having for its output light weight and at the same time high efficiency. In some cases the makers dispense with the solid forging and cast a yoke and angle pieces together. The magnet limbs in such cases are bolted to the yoke, and the cross section of the latter is made at least 1·5 times that of the wrought-iron limbs, in order that the induction may not be throttled.

Fig. 2 shows the S type of machine, in which the magnet is made of cast iron. The yoke is formed by the bed-plate, which is thickened up (as shown in the section, Fig. 3). Casting the magnet limbs connected by the thin piece A not only facilitates greatly the tooling, but, in consequence of the area of the joint being large, the magnetic resistance is diminished. The armature is here supported by cast-iron brackets bolted to the bed-plates, the bearings being of white metal. The smallest machine of the S type supplies ten 16 candle-power lamps, and the largest made up to the present supplies 850 lamps at 600 revolutions per minute.

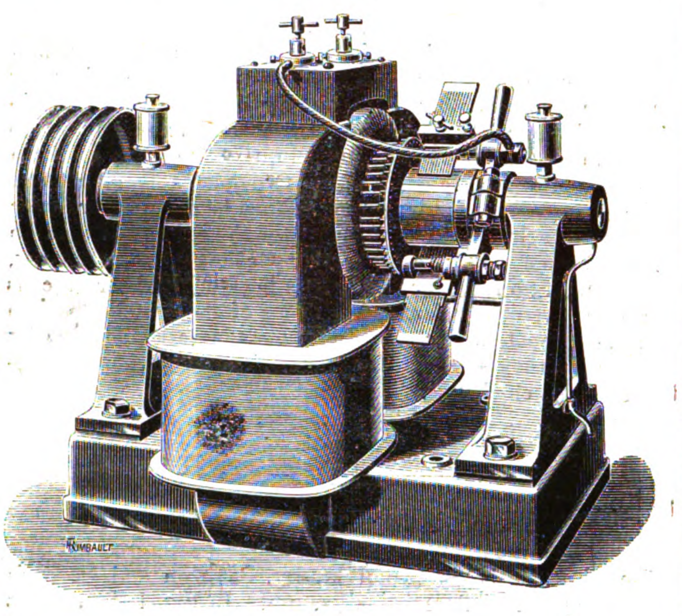

FIG. 2.

In both wrought-iron and cast-iron machines the magnet coils are wound on separate bobbins of sheet iron flanged with brass, which are, after being wound, slipped over the tops of their respective limbs into place. The collectors are of hard

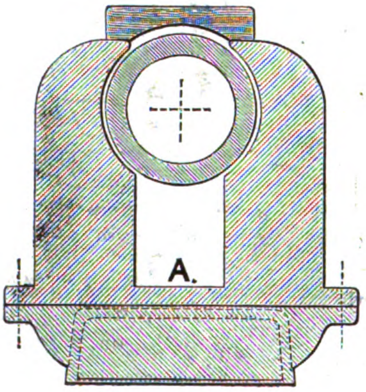

FIG. 3.

drawn copper insulated with mica, and the brushes are of soft brass wire.

DETNISIENSKI'S AUTOMATIC FIRE ALARM.

During the recent discussion at the Society of Telegraph-Engineers on Mr. R. Von Treuenfeld's paper on "Fire Alarms," it was pointed out by Captain Shaw that the system of automatic fire alarms possesses an inherent disadvantage, arising from the fact that unless a large number of these appliances are placed in all parts of the building, and several even in the same room, it is quite possible that a fire may arrive at serious proportions before the temperature of any one of the alarms rises sufficiently high to bring it into action. This difficulty appears to us to be overcome by a device of a very simple and ingenious character, which is described in a recent number of the Moscow *Technik*.

Two types of this apparatus are represented in Figs. 1 and 2. In Fig. 1 is seen an iron or copper tube, closed at one end, and containing a small quantity of mercury; at the lower or closed end of the tube is a projection which terminates in a ring encircling a pivot C, round which it can turn quite freely. The open end of the tube is closed with a stopper of wood or india-rubber, through which pass two insulated wires A and B. A piece of string, D, is attached to this end of the tube, by which it is held up in the position shown in the figure. The string D passes upwards to the ceiling, and from thence it is carried along the cornice around the room, while at any particular point it may be brought down to the level of the floor, or carried along the ceiling, so as to pass, for instance, over a gas bracket; finally it is terminated at some fixed point.

Now, when a fire breaks out, no matter in what part of the room it may arise, the string is sure to be burnt through at a very early stage. Immediately this happens the tube turns round the pivot, and the mercury closes the contact between A and B.

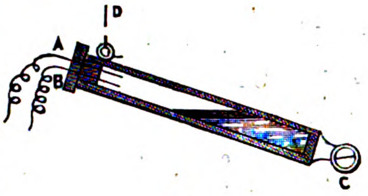

FIG. 1.

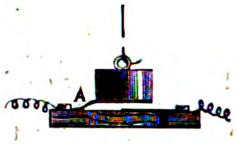

FIG. 2.

Fig. 2 shows another form of the apparatus. To a projecting bracket are attached two copper plates, A and B. A is separated from B by being bent, as shown in the figure. Over this bracket is a heavy weight, suspended as before by a cord passing all round the room. When the cord is destroyed by fire the weight falls, brings A and B together, and closes the circuit.

The apparatus is the invention of M. Detnisienski, and it certainly appears to meet the requirements of an automatic fire alarm in a very high degree.

ELECTRIC LAUNCHES AT THE BOAT RACE.

The boat race of 1888 may be remembered as the first in which the electric launch has made its appearance on the river. In a few years we shall doubtless find that for purposes of pleasure the steam launch will have well-nigh disappeared, for no one who has once experienced the comfort, pleasure, and handiness of an electric launch will ever again be content with its noisy and dirty predecessor. It should therefore be welcome news, not only to electricians but to all who are interested in the river, to learn that Messrs. Immisch are making active preparations for the establishment of floating charging stations on the Thames. The first of these will probably be stationed in the neighbourhood of Kew. A roomy hulk has been purchased, a 20 horse-power Fowler engine (under-type with loco-boiler) has been put aboard, and the dynamo will shortly be ready. Messrs. Immisch intend to place a fleet of launches on the river for hire, and will also charge accumulators at a fixed tariff. Every one must hope that this movement, which has been undertaken with the foresight and energy characteristic of the firm, will ultimately prove a real success.

On Saturday last the hulk in question was moored off Mortlake a little below the winning post, and a large party of electrical and other friends of the firm, who had been invited to witness the boat race, were on board. Before we had long been afloat, the look-out man espied a small craft making rapid headway up stream without sail, or oar, or other visible means of propulsion. As soon as she became visible to the naked eye, this proved to be the "Lady Cooper," flying the flag of the Electrical Power Storage Company. A vigorous

Digitized by Google

"ahoy!" soon brought her alongside, and complimentary visits were exchanged by officers and crews of each craft. We shall, however, reserve our detailed description of the "Lady Cooper" until next week, when we hope to have illustrations ready. It will be sufficient now to say that she is the largest and best-appointed electric launch which is yet afloat, and that she made her trial trip only the day before the boat race; so hurriedly, in fact, was she completed, that the proper screw not being ready she was provided for the occasion with a screw of smaller diameter, which happened to be at hand. But notwithstanding this disadvantage she was able to make no less than eleven knots per hour on the tideway.

When the race was over we bade farewell to the party on board Messrs. Immisch's "Charging Station," and embarked on the "Lady Cooper" for the return journey. The party were all in high spirits, and on the way down stream several scratch races with steam launches were indulged in, with results that led to the conclusion that the "Lady Cooper" could hold her own with any craft of the same size afloat on the river. After a very merry and somewhat adventurous voyage, the party broke up at the Temple Pier, with many expressions of satisfaction at the evident success of the latest venture of the E.P.S. Company, while the launch continued her journey to Millwall. We may add that the launch is named after Lady Cooper, wife of Sir Daniel Cooper, Chairman of the E.P.S. Company.

A SOUND RECEIVER FOR SUBMARINE TELEGRAPH LINES.

A method of receiving signals on submarine cable lines by means of the telephone, or rather, by a pair of telephones, has lately been proposed by M. Ader.* The author thinks it will be applicable wherever the mirror or Thomson recorder

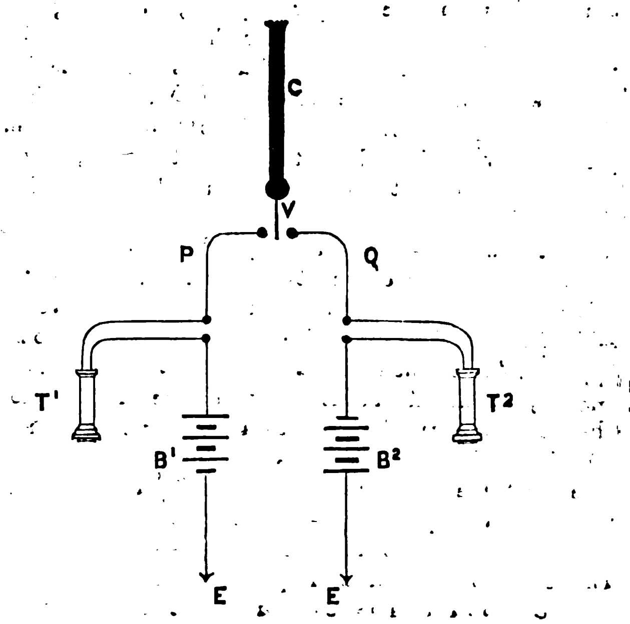

Fig. I.

is in use. Whether M. Ader has had an opportunity of actually carrying out the experiment which he describes does not appear; but the ingenuity of the idea will be appreciated, even if it should not prove to be of practical utility.

If a telephone be placed directly in circuit with a submarine cable working a mirror or a recorder no sound whatever is heard, because the rate of variation of the current is too slow to affect the diaphragm sensibly to the ear. And if an electrical or mechanical vibrator be introduced into the circuit, keeping all other conditions as before, we should simply hear the hum of the vibrator, and this would be unaffected by the signals. Suppose, however, that we had two independent telephones, and that the positive and negative currents received upon the cable were directed each into a separate telephone receiver, we should clearly have at least the basis of a method of reading the message by sound.

M. Ader seeks to develop this idea in the following way. In the diagram* (Fig. 1) C is the cable, which is connected with a vibrating tongue, V. The tongue is kept in rapid vibration by means of some quite independent electrical or mechanical device, which is not shown in the figure. The function of the vibrator is two-fold, first to interrupt the current so as to produce sound in the telephone; secondly, to direct the current alternately into the branch P to the left, and into the branch Q to the right, which contain the telephones T_1 and T_2 respectively. This distribution is effected quite independently of the direction of the current in the cable at the moment. But each of the branches P and Q contains also a battery B_1 and B_2, B_1 having its positive pole and B_2 its negative pole to earth, or *vice versa*. Now, suppose that a positive current is received upon the cable. The vibrator makes, it may be, a dozen or twenty contacts on either side while this current lasts, but if the strength of the batteries be suitably adjusted the telephone T_2 alone responds to the signal, the battery current being added to that received over the line. The telephone T_1 is mute, because the current is neutralised in this circuit by that of the battery. The battery current may, of course, be adjusted by the insertion of suitable resistances.

The weak point of this device evidently lies in the impossibility of adjusting the batteries B_1 and B_2, so as to balance the continuously varying currents received over the cable. But, on the other hand, it is quite possible, and even, we think, probable, that an operator would soon become sufficiently expert to read by gradation of sound, although neither telephone was absolutely silent.

M. Ader thinks that owing to the sensibility of the telephone it would be possible to work cables on this principle with smaller cores, and thus effect considerable economies in the construction of new lines.

* *Comptes Rendus*, March 19th, 1888.

* It should be stated that the diagram is not in the original paper, but we have added it for the sake of clearness.

"LIGHTNING AND THUNDERBOLTS."

If the amount of space afforded by the daily press to reporting and commenting on the Meteorological Society's meeting last week may be taken as a measure of popular interest in its proceedings, the President and Secretary have reason to be gratified with their choice of subjects for discourse on that occasion. With that professional felicity which characterises the newspaper reporter, the doings of the evening appeared next day under the attractive head line of "Lightning and Thunderbolts," and as one of the lecturers dealt with atmospheric electricity, and the other with thunderbolts, whilst the exhibition on view in the premises was intended to illustrate both, we have felt that we cannot do better than adopt this imposing title for the few observations we have to offer on the incident taken as a whole—that is to say, the papers, the exhibition, and the newspaper comments thereon. We are led to adopt this course by the further consideration that whatever may be said of the exhibition—which, besides being "extremely interesting," as the newspapers described it who did not understand it, was useful and instructive to the experts who did—the lectures were addressed to a popular rather than to a scientific audience; and it is therefore rather curious to note what the popular audience thinks about them. The president even apologised—needlessly, it seems to us—for his mercilessly scientific treatment of atmospheric electricity. That our knowledge of atmospheric electricity is making progress our own columns continue to bear testimony, but that Dr. MARCET was justified in conveying the impression—which his paper certainly did convey—that there is little left to learn, we are certainly not prepared to admit.

It is true that we possess a natural theory of the *modus operandi* by which the potential of a rain-cloud may rapidly rise to a tremendously high value, but the fundamental question of the ultimate origin of the charge is still in dispute—or, since no one who is really competent to form an opinion cares to dogmatise on the question, we should rather say is still under discussion. To take only one other outstanding problem, the formation of hail may or may not be primarily due to an electrical cause. Prof. COLLADON has a theory on the sub-

Digitized by Google

ject, which was described by Dr. MARCET as follows :—"The heavy rainfall preceding a hail shower carries a mass of air before it and causes a strong downward wind; this is obviously attended with a powerful suction or a partial vacuum in the upper clouds. At once a fall of temperature takes place which causes a condensation of moisture into frozen particles. The down drift from the shower of rain heralding a hail storm is productive, according to M. COLLADON, of upward and side currents of air which drive up the sleet and tear the rain cloud into a number of separate cloud masses, each of them powerfully electrified; the particles of frozen moisture are now attracted and repelled between these cold clouds while driven about by the wind, thus increasing rapidly in size until they become so heavy that they fall to the ground in the form of hail."

A very ingenious suggestion on this subject was made some little time ago by Prof. G. GOVI, and although it has since been withdrawn by its author, owing to the negative results of experiments which he has tried, it is yet of sufficient interest to be alluded to. Prof. GOVI supposed that aqueous vapour might exist in still air in the higher regions of the atmosphere at a temperature under which its condition would resemble that of a solution of salt in the super-saturated state. It is well known that a sudden shock, or, better still, a small crystal dropped into such a solution, will instantly bring about crystallisation. In the same way Prof. GOVI suggested that an electrical discharge might cause the sudden congelation of the vapour in the higher regions of the atmosphere. But on putting this supposition to the test of experiment by causing a powerful electrical discharge to pass through a super-saturated solution of sulphate of soda in a sealed glass vessel, contrary to reasonable expectation it was found that the disturbance *did not* set up crystallisation. We think, however, that Prof. GOVI's ingenious suggestion will bear further investigation before being finally discarded.

Returning to Dr. MARCET's paper, whatever may have been its author's intention, we certainly find that the impression produced upon the public mind, as represented by the columns of the daily press, was that which we have already intimated, namely, that very little is left to be learnt in this department of science. For instance, the *Standard* leader writer talks as follows: —"But whatever conflict of opinion may be permissible on this point [*i.e.*, the cause of waterspouts], it is clear that none is allowable in regard to the Aurora Borealis Australis" [*sic*]. If the writer had intended to say that the known data were insufficient to form the basis of any reasonable difference of opinion we should have been inclined to agree with him. But this is not his view, and after retailing a crude explanation (which, by-the-bye, Dr. MARCET only quoted as being "generally considered" probable) the article finishes up as follows:—"And thus the electrician deprives us of the last fragment of romance which clung to the most picturesque of Northern atmospheric phenomena." Against this idea in general—an idea which runs all through the article, and which is still too widely prevalent, that science is fatal to mystery, and, therefore, in a large degree to the poetry of life—it is, perhaps, not worth while here to make any serious protest. As a matter of fact, both romance and poetry have gone on increasing side by side with the advances of science, the beauty, the mystery and majesty of natural phenomena being none the less inspiring for being better understood.

Turning now to Mr. SYMONS' thunderbolt paper (which our readers have already had an opportunity of reading), we find an excellent *exposé* of a popular superstition, which, although of an extremely natural and excusable character, ought to have been exploded long ago. Our readers have probably already enjoyed a good laugh over the clinkers, and sandstone-nodules, and lumps of brick and coal which have done duty at various times as thunderbolts. Mr. SYMONS mentioned, by-the-bye, that some of the clinker-thunderbolts which fell from the Kentish Town fire engines were sold at 10s. and 12s. a-piece. But although the purchasers must be admitted in these cases to have had a very dear bargain, yet certain other cases cited by Mr. SYMONS suggest the idea that the track of a reputed thunderbolt—that is to say, the hole which is sometimes dug in the soil by a lightning discharge—will often well repay exploration. In one such case an antique cannon ball was thus discovered, and in another case—not, however, mentioned in the paper—an ancient British celt came to light, Now it seems reasonable to assume that the existence of these metallic bodies buried under the soil had something to do with determining the path of the lightning. And it is also clear that a buried treasure would be as efficient for the purpose as a celt or a cannon ball. Hence, lightning tracks in the soil should *always* be dug up by the first finder. *Verb. sap.*

THE ELECTROLYSIS OF COPPER SULPHATE IN STANDARDISING ELECTRICAL INSTRUMENTS.*

BY A. W. MEIKLE (Thomson Experimental Scholar).

Owing to the great increase in the use of electricity in recent years, and the consequent importance of having accurate measuring instruments, it is necessary that electricians should have some accurate means whereby they may have their standard instruments readily and cheaply checked from time to time. Much might be said for a national recognition of this fact by the establishment of a system of electrical standards, just as we now have national standards of length, weight, &c.; but such a subject is beyond the province of this paper, in which I propose to give a description of the electrolysis of copper sulphate, which has been employed for standardising purposes in the Physical Laboratory of Glasgow University for the last two years, with the most satisfactory results.

A paper communicated by Mr. Thomas Gray to the *Phil. Mag.* for November, 1886, dealt with the question of the reliableness of copper electrolysis as compared with silver. The conclusion drawn from the investigation described in that paper was, that while silver in the hands of a trained experimenter left nothing to be desired in point of accuracy, still it is open to the objection that it is very costly where large currents are used, and requires great care in making the experiments. Copper, on the other hand, has the advantage of simplicity in manipulation, and where attention is given to a few necessary precautions great accuracy can be obtained. As an example of the difficulties in the use of silver I may mention that the deposit, which is always crystalline in form, requires careful handling, in order to prevent loss in drying or weighing, and in order to get it thoroughly adherent to the plate the area of the cathode or gain plate should never be less than 200 or more than 400 sq. cms. per ampere. With copper the deposits for areas exceeding 20 sq. cms. per ampere is thoroughly adherent to the plate, of which, indeed, it forms an integral part. Thus, in making an electrolysis of copper sulphate for 100 amperes, a current density of 1 ampere to 50 sq. cms. would give excellent results, and the total area of gain plates would only be 5,000 sq. cms., while were silver used the area would require to be from 20,000 to 30,000 sq. cms.

One disadvantage which copper has is its readiness to oxidise when exposed to the air, more especially when being taken out of the sulphate of copper solution, but if the mode of cleaning and drying the plates, both before and after electrolytic action, which is described in this paper, be employed, this difficulty is easily overcome. I have kept plates for a week after being treated in this manner without being able to observe any change of weight, as indicated by a chemical balance which is sensitive to $\frac{1}{10000}$ of a gramme.

Another point which has to be taken into account is the fact that the plates lose weight in the solution at a rate varying with the

* Paper read before the Physical Society of Glasgow University, January 27th.

Digitized by Google

area they expose to the action of the acid which is contained in all electrolytic solutions of sulphate of copper capable of giving reliable results. This question was gone into very fully by Mr. Gray about two years ago, and the results are given in his paper on electrolysis which is referred to above. It has again been gone into when making some experiments on the effect of temperature on the loss of weight of the plates in the solution. The results of these experiments, which were made by passing the current through 10 cells in series each of which had a different area of plate, is to confirm the experiments made by Mr. Gray, and to show that the amount of variation from the true electro-chemical equivalent of copper due to differences of current density can be allowed for with great accuracy. Before describing particularly the results of these experiments, it may be well to refer briefly to the apparatus used.

ELECTROLYTIC CELLS.

The electrolytic cell found most convenient for small currents consists of a round glass jar nearly filled with sulphate of copper solution, into which three vertical plates, with their services parallel and about 15 mm. apart, are held by means of rigid platinoid clips. The two outside clips are joined together, and the plates held in them are the anodes or loss plates (see Fig. 1). Two loss plates are always put into each cell, one on each side of the gain plate, so that the gain plate may receive a uniform deposit on each side. The centre clip, which is well insulated from the two others, holds the cathode or gain plate. The clips for holding the gain plates are formed of straight pieces of No. 6 platinoid wire, about 6in. long, a portion of which, about 4in. long, is filed flat, and on to this another piece of platinoid, bent so as to form a powerful spring, is soldered at *a*, so that the two ends of the pieces form a firm contact at *b* (Fig. 1). A binding screw for fixing on the electrode is screwed on to the other end at *c*. Several of the clips so formed are firmly clamped on to a rectangular wooden frame by screwing a strip of wood down on the top of them, the portion of the clip between the wood being well insulated by being covered by a piece of thick india-rubber tube.

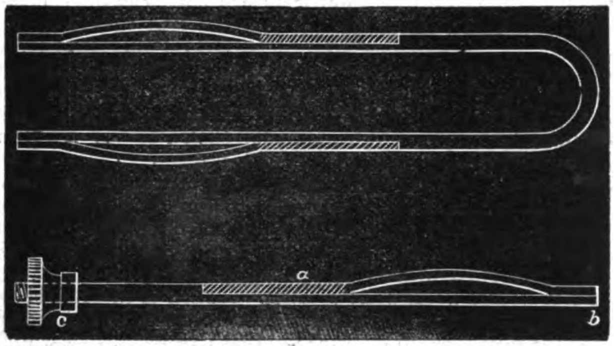

FIG. 1.

The clips for holding the loss plates are formed in the same manner as the gain plates, but are made in pairs by bending a piece of No. 6 platinoid wire into the shape of a U, with about three centimetres between its ends, and then soldering on the springs as already described.

These clips are insulated and fixed on to the frame on the opposite side from the single clips, so that the end of the latter comes just between the two ends of the former, as shown in Fig. 2. A flexible, covered copper wire, of convenient length to enable the cells to be joined in series if desired, is permanently soldered on to the bend of the double clips. This mode of placing several sets of clips on a wooden stand is found very convenient, as the plates can readily be adjusted in their position, or taken out without disturbing any of the other arrangements.

This form of clip suits very well for currents up to about fifteen amperes by joining the cells in series or parallel, as may be necessary. In using electrolysis for small currents up to two amperes, it is advisable to use two or even three cells in series, as with small deposits a check is thus obtained on the weighings, or any defect in an individual cell. With currents from three to 15 amperes I prefer still to use this form of clip, and a sufficient number of cells in parallel, each having gain plates of about 130 sq. cms. in area, so that the plates, owing to their comparative lightness, may be weighed on the chemical balance—the additional number of weighings being more than compensated for by the additional accuracy obtained.

For currents such as are used in standardising a deca or hecto-ampere balance, owing to the large amount of copper deposited, such delicate weighing is not necessary, and a balance sensitive to about two milligrammes may be used; but even were an error of five milligrammes made in weighing the plates of an electrolysis for 50 amperes continued for one hour the error would only amount to about $\frac{1}{100}$th per cent. For high currents, such as these, a large earthenware cell is used, which is shown in Figs. 3 and 4. A wooden frame is fitted on to the

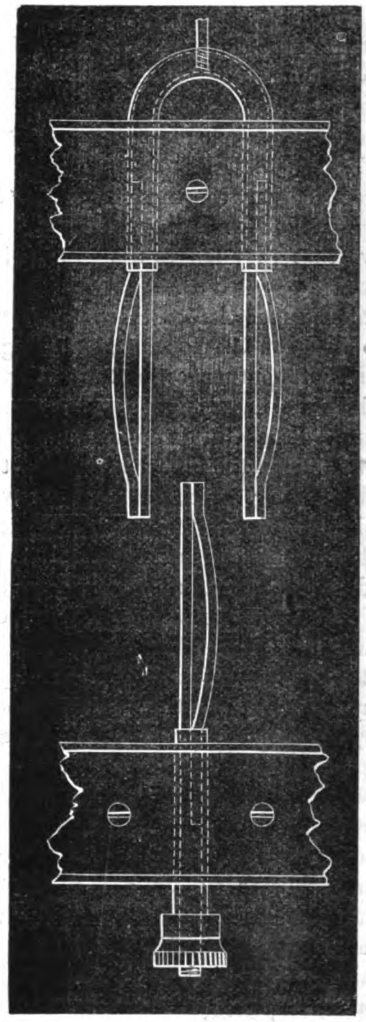

FIG. 2.

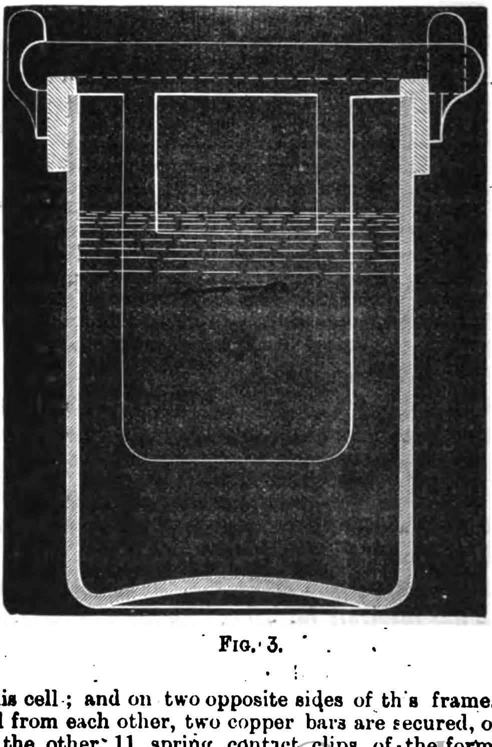

FIG. 3.

top of this cell; and on two opposite sides of this frame, and well insulated from each other, two copper bars are secured, one having 10 and the other 11 spring contact clips of the form shown in Fig. 5. The plates for this cell are made of sheets of copper, each of

Digitized by Google

which has a rigid strip of copper soldered to its top edge, and projecting about two inches on each side of the plate. On putting the plates into the cell one end of this strip fits into a clip and the other rests in a vulcanite notch on the other side of the cell. Each of the plates when in position exposes a surface of 1,100 square cms. to electrolytic action, so by putting in the proper number of plates the cell can be used for currents up to 200 amperes. The plates and clips are so arranged that one gain plate comes between two loss plates, and the latter always exceed the former in number by one. As the plates, when all are put in, are very close together, two glass tubes bent so as to form U's, and long enough to reach to the bottom of the cell, are hung over each loss plate to prevent any danger of the plates touching. Two flexible electrodes

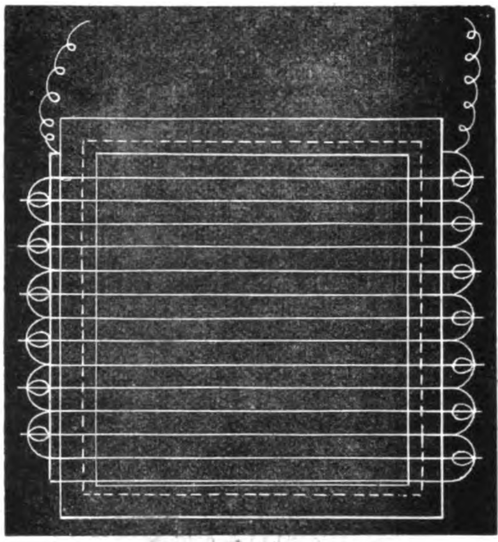

FIG. 4.

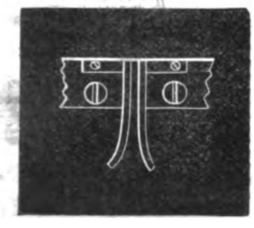

FIG. 5.

suitable for dipping into mercury cups are attached to the bars carrying the clips.

The Solution for the Electrolytic Cells.

The solution used is made by dissolving commercial copper sulphate in pure water as it comes from the Glasgow Corporation's water pipes until a density of from 1·15 to 1·18 is obtained, and then adding 1 per cent. of free sulphuric acid. For all the experiments mentioned in this paper the solution used has been of a uniform density of 1·175, but it has been found that a variation in density from 1·1 to 2 makes no difference in the nature or quantity of the deposit. With solutions made up as described perfectly accordant results have invariably been obtained. The solution should not be used too often, as the acid is after a time exhausted by action with the plates, and it has been found from experience that unless the solution is decidedly acid the plates are oxidised in the solution, and very irregular results are obtained, which are quite valueless for accurate standardising. The table of curves (A) shows very clearly the difference between results obtained from solutions which have free acid and those which have not. The five curves are taken from experiments made with ten cells in series and different areas of gain plate in each. The abscissæ are areas of gain plates in square centimetres per ampere, and the ordinates are deposits in grammes. It will at once be observed that the curves I., II., and III. are exactly similar in form. Curve I. is the mean of about 12 experiments made with free acid in the solution. Curves II. and III. are from two single experiments also, with about 1 per cent. of free acid in the solution. Curve IV. is taken from an experiment made with solution which had been used too often, and the results are irregular owing to oxidation of the plates in the solution. Curve V. shows the results obtained from a solution in which some copper oxide had been dissolved, so as to withdraw all the free acid. The gain plates were found to be very much oxidised when taken out of the solution, and had a dark brown colour instead of the bright metallic surface which they have when taken from a solution which contains acid.

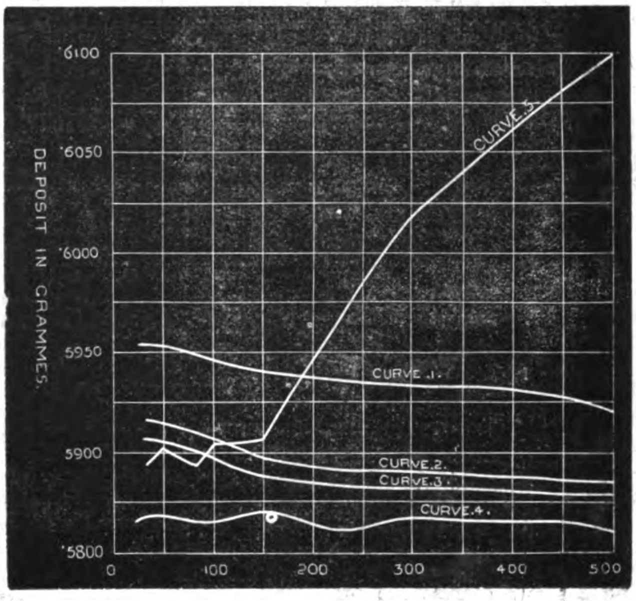

DIAGRAM I.

Preparation of Plates.

The gain plates used are made from ordinary high conductivity sheet copper about $\frac{1}{10}$ths of a millimetre in thickness. For the smaller cells they are cut in the shape shown in Fig. 6, as this form of plate, owing to the flexible tongue, is very easy to adjust in its position, and when in use the whole plate is immersed in the solution except the narrow tongue necessary to hold the plate between the contact clips, thus leaving a very small area exposed to any possible oxidation by the atmosphere. This form of plate has also the advantage that the area exposed to electrolytic action can be got at once, or may be permanently stamped upon the tongue, and the proper equivalent for the current density can be taken without having to measure the area covered by the deposit. The edges of the plate are all smoothed, and the corners rounded off, as the deposit is apt to form on any rough edges, especially if a high current density is being used, or if the current is being run for a long time. When this has taken place, the plates, owing to the roughness of the surface, are not so readily dried, and the risk of oxidation is increased, as is also the risk of losing part of the deposit should the plate accidentally strike against any object. The surface of the plates is burnished with fine glass paper until perfectly bright and smooth, then rubbed with a piece of clean cloth, and finally wiped gently with a piece of silk to remove any shreds, after which they are ready for weighing. Another plan, which has been successfully employed, is to polish the plate with

FIG. 6.

silver sand and water, to which a few drops of sulphuric acid were sometimes added. The plates are then washed in clean water to remove the sand, and placed in a vessel containing pure water, with a little sulphuric acid in it to remove any oxide which may have formed during the washing. From this they are taken one at a time, quickly dipped in fresh water, and dried immediately on clean white blotting paper, then held before a fire to remove any trace of

Digitized by Google

moisture which might remain. The method which has been found most convenient, however, is to place a sheet of No. 1 glass paper on a wooden roller and spin it in a turning lathe, holding the plate against it by a pad. When the plates have been burnished by this method, the sand paper, which is only held on the roller by two springs, is removed, and a piece of rough cloth put on instead. On this cloth the plates receive a final polish to remove grains of sand, are then wiped with a piece of silk as in the first method, after which they are ready for weighing. Care should be taken never to touch the portion of the plate intended for immersion in the cell with the fingers, as by so doing the surface is spoiled for a deposit and the mark of the finger is seen distinctly after the electrolytic action.

Loss plates are also made from high conductivity copper, but from a thicker sheet, so that they may last for some time. No great trouble need be taken with them, except to see that they are not put into the liquid when badly oxidised, in which case the free acid in the solution unites with the oxide on the plate, and the solution suffers in consequence, as I have already explained. For this reason, too, the loss plates should never be left in the solution when not in use, but should be taken out and placed in water with a few drops of H_2SO_4 added, or, if they are not likely to be required again for some time, they should be dried and put past.

Size of Plates.

Loss plates should never have an area of less than 40 sq. cms. per ampere. If the area is much less than that the resistance of the cell becomes high and variable owing to the formation of copper oxide on the plate, and if it be made very small gas is given off at its surface, making it impossible to keep the current steady, and giving a result of no value for accurate standardising. The gain plates should never expose a surface of less than 20 sq. cms. per ampere. When too high a current density is used the deposit is not so adherent to the plate, and a portion may be lost in washing and drying. It is always best to use an area of from 50 to 100 sq. cms. per ampere, using the larger area for currents which are intended to run for some time. By doing so any little roughness round the edges is avoided, and in consequence the plates are easier to dry.

As already mentioned at the beginning of the paper, the amount of copper deposited by a given current varies with the area of the plate exposed to the corrosive influence of the free acid in the solution of copper sulphate. This variation is not the same as it would be were no current running; in reality it is less, from which it would seem that the current exercised some protecting power. This subject has been very fully investigated in the physical laboratory, as also the effect of temperature on the rate of loss, and the results of the experiments are shown in the Table of Curves No. II., and the two tables of numbers which I shall speak of presently.

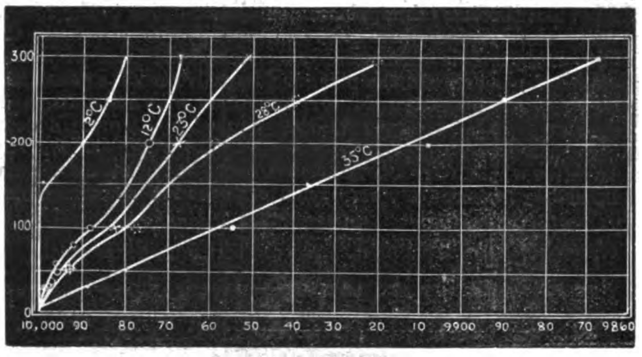

Diagram II.

The experiments were made with ten cells in series, all carefully insulated from each other, and each cell having a different area of gain plate, the extreme range being from about 30 to 50 sq. cms. per ampere. The solution used in all cases was 1·17 in density, with 1 per cent. of H_2SO_4 added. From former experiments described in Mr. Gray's paper on electrolysis before mentioned, no difference could be observed in the amount or appearance of deposits from solutions containing percentages of acid varying from ½ per cent. to 5 per cent. at a temperature of about 12deg. C.; but owing to the very rapid consumption of the free acid in the solution at the higher temperatures, fresh solution was used each time.

The curves show the results obtained for different areas of cathode or gain plate, and each curve is for a different temperature between 20deg. C. and 35deg. C. It will be observed that they all converge rapidly towards the point of crossing, which shows that the same deposit would be had at all temperatures were it only possible to use a small enough area of gain plate. The curves were produced to cross the line of ordinates, and the point of crossing was taken as 10,000 and the other points reduced to correspond, so as to render percentage corrections easy for different current densities. The ordinates are therefore numbers proportional to the weight of copper deposited in grammes, while the abscissæ are areas of gain plate in square centimetres per ampere.

The curve for 2deg. C. is the mean of three experiments, which were in very close agreement. It is rather curious that for a range of current density almost up to 130 sq. cms. per ampere there is no effect made by variations in the area of gain plates, but the same tendency is shown in the curves for 12deg. C., 23deg. C., and 28deg. C., although to a much smaller extent. The curve for 12deg. C. is the mean of a large number of experiments which were in very good agreement among themselves. It is the same curve which is shown as the mean curve in the first table, but on a different scale. The effect of temperature from 10deg. to 15deg. C., which is about the ordinary range of temperature in the Physical Laboratory of Glasgow University, is very small and may be neglected. Indeed, with a gain plate of 50 sq. cms. per ampere, the total variation in the corrected equivalents for 12deg. and 28deg. C. is only about $\frac{1}{18}$ per cent. The curves for 23deg. C. and 28deg. C. are two single experiments, while the curve for 35deg. C. is the mean of two experiments which were in good agreement with each other. A glance at the curves will show how important the question of temperature becomes at the high points. In countries where 28deg. and 35deg. C. were normal temperatures a very careful allowance would require to be made for any variation. The Table No. I. gives the numbers from which the second table of curves is taken, and Table No. II. gives the corrected electro-chemical equivalents, as calculated from these numbers for different current densities from 1 ampere to 50 sq. cms. up to 1 ampere to 300 sq. cms.

Table I.

Standardising Arrangements.

The arrangements for standardising consist, as shown in the diagrams, in joining in series a constant battery, the instrument to be standardised, the electrolytic cells, and a variable resistance. Care should always be taken to join the instrument directly on to the electrolytic cells and have that portion of the circuit well insulated, so as to be sure that the instrument is recording the exact amount of current which is going through the cells.

The simplest form of arrangement is shown in Fig. 7 and is suitable for currents up to ten amperes. The variable resistance used in this case is one of Sir William Thomson's rheostats. For currents up to one ampere a high resistance rheostat of platinoid wire is used, and for currents above that point a large rheostat of stranded copper wire—the potential of the battery being first adjusted to suit the special case. With large currents beyond the carrying power of any rheostat, a conductivity bridge is put in circuit for the purpose of varying the current. This bridge consists of a number of platinoid U's of sufficient length not to heat much with any current which the potential of the battery can send through them. By dipping the two ends of these U's in two parallel mercury troughs any desired conductivity can be put into the circuit. Fig. 8 shows two of the large bridges, one of which is standing in the mercury troughs, while the other is standing on the insulated sides. The large bridges are kept apart by wooden distance pieces, as shown in the figure, while the small ones are supported on strips of wood through their whole length, and are fitted with thick copper ter-

Digitized by Google

minal pieces. The copper rheostat before mentioned is joined in parallel to this bridge, and the whole arrangement, as shown in Fig. 9, simply takes the place of the rheostat in the former arrangement. We have found this last arrangement very useful for standardising instruments, as, with the battery power at our disposal, any current up to 500 amperes can be had by continuous

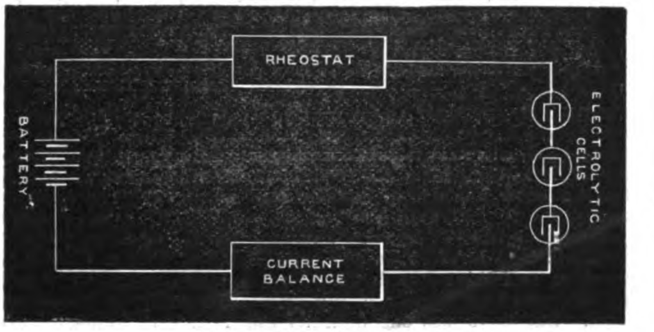

Fig. 7.

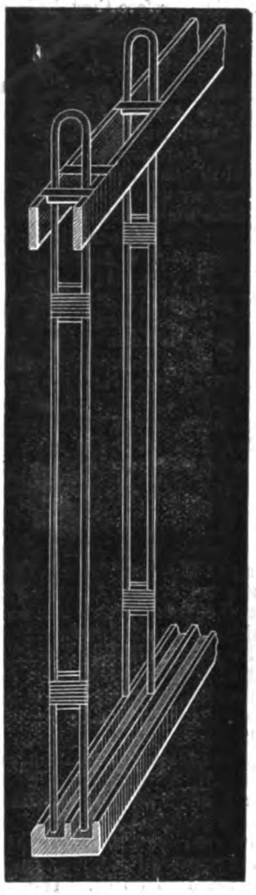

Fig. 8.

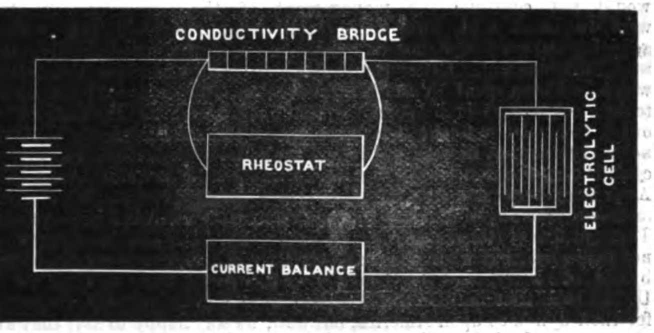

Fig. 9.

steps. The apparatus being arranged as stated above, trial plates of the same area as the gain plates to be used are put into the electrolytic cell, and the current is adjusted to the required reading on the instrument. The circuit is then broken, the trial plates are replaced by the cleaned and weighed gain plates, and current is again made—the exact second being noted on an accurate time keeper. This instrument should be found very nearly to record the desired reading, and should at once be adjusted by turning the rheostat, and by that means be kept steady during the experiment, any error arising from the current not being at the proper strength on starting is very small. As a rule the current, when previously adjusted as above, is, practically speaking, exactly correct when made for the standardising, but should it chance to be even so much as 5 per cent. wrong, an amount which, with the precautions taken, is entirely out of the question, it can easily be set right in at most 10 seconds with apparatus such as has been described, and the whole error on an experiment lasting for one hour would only be about $\frac{1}{140}$ per cent. The current should run until the amount of the deposit will be such that any possible error in weighing, or in starting or stopping the current, is practically speaking eliminated. In breaking the current the exact second is again noted, and the plates quickly removed from the clips, and placed in a glass vessel containing pure water with a few drops of H_2SO_4 added to prevent oxidation. From this they are taken one at a time, dipped in pure water, then dried and weighed as before described in the process of cleaning with silver sand. The jaws of the clip are always opened before putting in or taking out the plates, so that there will be no error due to loss of weight by the friction of the plate with the spring contacts. The zero of the instrument is always carefully carefully noted before and after the experiment.

Standardisings of Sir William Thomson's Standard Current Balances.

As showing the degree of accuracy which can be obtained by the electrolysis of copper sulphate, I shall briefly give the results obtained from the standardisings of Sir William Thomson's Standard Current Balances, the constants for which have been determined by the methods I have described. There are in the Physical Laboratory at the present time seven of these balances, whose measuring range is as follows :—

1.	Hecto-ampere balance;	range		from	20 to 500	amperes.
2.	Deca	,,		,,	,, 4 ,, 100	,,
3.	Ampere	,,		,,	,, 1 ,, 25	,,
4.	Deci-ampere	,,	(a)	,,	,, 2 ,, 50	deci-amperes.
5.	,,	,,	(b)	,,	,, 1 ,, 25	,,
6.	Centi-ampere	,,	(a)	,,	,, 2 ,, 50	centi-amperes.
7.	,,	,,	(b)	,,	,, 1 ,, 25	,,

(1.) The constant of the hecto was first found by electrolysis and the curve calculated from the result of the experiments. On being again checked by electrolysis on December 2, 1886, with its adjusted watts, instead of 100 amperes, as indicated by the instrument, the mean of two experiments gave a current value of 99·996 amperes.

(2.) The deca-ampere balance was standardised by direct comparison with the hecto, and on being checked by electrolysis on February 15, 1887, a result of 49·978 amperes was obtained against a current of 50 amperes read on the instrument. The latest comparison still shows the instrument to be in perfect agreement with the hecto. It has also been twice standardised by electrolysis at intervals of five months, which gave results respectively of $\frac{1}{25}$ per cent. and $\frac{1}{33}$ per cent. too low.

(3.) The constant of the ampere balance was determined by electrolysis, and on afterwards being compared with the deca it showed a variation from that instrument of $\frac{1}{60}$ per cent.

(4.) The constant of deci-ampere balance (*a*) was twice determined by electrolysis, which gave a difference of $\frac{1}{500}$ per cent. between the two standardisings. Its weights were taken by calculation from the result of these experiments, and on being again checked by electrolysis the result showed $\frac{1}{80}$ too large on a current of 4 amperes as read on the balance.

(5.) Deci-ampere balance (*b*) was standardised by direct comparison with centi-ampere balance (*b*), and on being afterwards compared with deci-ampere balance (*a*) showed a variation from that instrument of less than $\frac{1}{100}$ per cent.

(6.) The weights for centi-ampere balance (*a*) were determined by direct comparison with an old and now disused form of deci-ampere meter in June, 1887. Since that date it has been checked at intervals by four separate electrolysis experiments, which gave results respectively of $\frac{1}{14}$ per cent., $\frac{1}{14}$ per cent., $\frac{1}{17}$ per cent., and $\frac{1}{18}$ per cent. too large, which is very satisfactory when the small weight of the deposit is considered. Compared with deci-ampere balance (*b*) this instrument is in absolute agreement.

(7.) The constant of centi-ampere balance (*b*) was determined by direct comparison with centi-ampere balance (*a*), from which, though comparisons have been made from time to time for the last six months, no variation whatever can be observed.

We have thus a chain of instruments measuring from one centi-ampere to 500 amperes, which are, practically speaking, in absolute agreement among themselves, and whose constants have been determined separately, and in many cases by different observers, by the process of electrolysis of copper sulphate described in this paper. This fact not only proves the constancy and accuracy of

Digitized by Google

the instruments, but also establishes beyond a doubt the great value of the method of standardising, and that it is equally applicable to currents of all magnitudes.

REVIEWS.

Money, and Money Problems. By Shield Nicholson, M.A., D.Sc. (London and Edinburgh: William Blackwood and Sons, 1888.)

We have read this work with considerable interest, and we have gained from it a clearer insight into the nature and relative importance of the great problems of political economy which are now pressing for solution. The author contrives to make a subject which is usually considered typically arid and repellant not merely tolerable, but positively refreshing from the clearness and simplicity of his style. The first part of the volume is devoted to a non-polemical exposition of the leading principles of the science of Money. The second portion consists of a series of detached essays, some historical and some argumentative. In the latter the author stoutly maintains the superiority of the bi-metallic standard.

THE MAXIM-WESTON ELECTRIC LIGHT COMPANY (LIMITED).

The seventh annual ordinary general meeting of this Company was held at the Cannon-street Hotel on Wednesday, under the presidency of Mr. Hugh Watt, M.P.

The SECRETARY (Mr. John Wright) having read the notice convening the meeting,

The CHAIRMAN proposed the adoption of the report and accounts. He said he did not wish to occupy the time of the meeting unduly, but he thought it might be desirable to enter into certain particulars seeing that the present list of shareholders was entirely new, as compared with that when the present Board, or such of them as remained, undertook the reconstruction of the Company, relieving it from its financial difficulties, and placing it upon, if possible, a sound basis. Having taken office, the facts were disclosed to them that the Company was virtually insolvent, unable to carry on, with no profitable business in hand, with contracts entailing a loss of over £10,000 a year, and the near prospect of liquidation. The share list at that date consisted of less than 1,000 shareholders, and so little faith had they in the future of the electric light, the fever era having passed away, that the new capital subscribed by them to prevent the Company from passing into liquidation amounted to about £550. It was therefore necessary on the part of gentlemen who, looking into matters, thought there was a future for electric lighting, to put their hands in their pockets and, with the assistance of their friends, to find sufficient capital to carry on the Company. That capital was found to wipe off the debts of the old Company, to get rid of the old factory, which cost nearly £1,000 a year, to get rid of city contracts and other unprofitable work entailing a loss, as he had said, of over £10,000 a year, and to put the Company on a sound financial basis. That was four years ago. During that period the original shareholders or those who had since come in had subscribed an amount of capital to the Company, but the bulk of the new capital to enable them to effect new works, to lay down adequate plant to carry on a larger business—all the necessary money had been found by the Board with the exception of £4,000 to £5,000 subscribed by the shareholders to date. The amount which the present Board had returned in dividend had been twice the amount mentioned as having been subscribed by the shareholders. For the previous two years they had paid dividends of 7½ per cent. and 5 per cent., and not unnaturally the shareholders might have expected a dividend in respect of last year's working. He also fully expected up to November last that they would be able to pay a dividend. At that date they had carried out business and had entered into provisional contracts, entitling him to assume that, after paying a dividend of 5 per cent., there would be a considerable balance remaining. The three large contracts—over one of which they had spent, more or less, three months—ultimately fell through, leaving them with a deficiency as compared with the previous year of something like £3,000 in the profits. They had carried through an amount of business, looking to the weight of plant sold, greater than that of the previous year; but they had made that position emanating from sources which did not exist at the beginning of 1887, and which was not based upon commercial principles or on enduring lines—the principle of selling one pound's worth of plant for less than 20s. He then asked the secretary to read a letter which had been received from Mr. Dever relative to certain items in the accounts. Continuing, he said that some two or three days before Mr. Dever's letter had been received the Directors, having arrived at the same conclusion as to bad and doubtful debts, decided on transferring the whole of the balance of profit and loss account, namely, £1,555, to the reserve account, to meet bad and doubtful debts. With respect to the increase in the machinery, plant, and tools account, it had arisen from the fact that they had found that to manufacture the heavier dynamos up to 500 lights would necessitate the putting down of stronger lathes and other machinery. That had been done, and consequently the account had increased. The additional plant put down at the factory had enabled them to manufacture Maxim-Weston and Watt dynamos. He agreed with Mr. Dever that it was desirable that they should add nothing more to patents account, but as long as the present competition was going on and improvements were coming out monthly, unless they permitted themselves to retrograde, they must continue to adopt those improvements. The expenditure incurred had been entailed entirely on Maxim and Weston patents. Reference was made in the report to the fire at the American factory last year, a circumstance which had pretty well deprived the Company of the incandescent lamps for the carrying out of which the Company was originally formed, and without which they had been placed at very decided disadvantages. Their stock of lamps had not been adequate for the supply of their customers, and they had been compelled to tender for Swan lamps. The result was that customers had said, "We thought you had a Weston system, and in coming to you one of the contentions of your Company has always been that you supply a complete system, every detail of which is the invention of one man." With respect to the manufacture of incandescent lamps, a good many present were not aware of the fact that after he joined the Board he went exhaustively into that question, with the result that he found that incandescent lamps were costing them something like 17s. 6d. each, and he believed before he finished his experiments that he arrived at the conclusion that they could be manufactured at something like 3s. 9d. That fact had necessitated the dismissal of a very large number of supernumeraries, and great savings were effected. But there was one difficulty which they could not get over, the difficulty of durability. They could not succeed in manufacturing those lamps possessing a life time of half of those which were made by the American Company. He therefore thought it was best to cease their manufacture, a proceeding which entailed a large loss, and to throw themselves on the American Company. The new lamps were very good, and, he thought, compared favourably with any in the market. There had been some very tall talk on the part of the chairman of another company in connection with the incandescent lamp. He maintained now, as he had before, that the action of the Edison and Swan Company in securing what they seemed to regard as an entire monopoly of incandescent lamps was essential in the interests of the Maxim-Weston Company. As far as their Company was concerned they had been involved in no litigation with the Edison and Swan Company, and as to the question of litigation generally, it was not one that greatly concerned them, for they had the guarantee of the American Company that in the event of any litigation they would hand over to the Maxim-Weston Company a large sum of money, so that the litigation, if it ensued, which he hoped would not be the case, would be virtually by the Edison and Swan Company against the United States Electric Company. With respect to the contention of Mr. Forbes, he might say that the Maxim patent was attacked by the Edison people, but it succeeded, and that the Weston patent, which was attacked by the Cheesborough patent, also succeeded. As far as he could see, therefore, they had perfectly sound patents, which were unimpeachable, or, if impeached, could be upheld. As long as the Edison and Swan Company did not prepare to attack this Company they had no intention to attack the Edison and Swan Company. During the past year they had, in the shape of sending out estimates and general work, done a great deal more than during the previous year; but for the reasons he had stated, they had not succeeded in obtaining as many orders. Whenever the Company had made a reduction of 5 per cent. their competitors had made one of 10 per cent., and in many cases sustained a manifest loss on the contracts. He then went at considerable length into the principal items of the balance-sheet. He had, he said, already explained the item for patents. The auditor, very fairly, he thought, suggested for 1886 that the item, expenditure for wages, salaries and improvements should be detailed, and that had been done week by week. He did not see that they could do anything more than they had done. If the sum was to be placed to the debit of working expenses, it would, in his (the chairman's) view, be inequitable; and in the second place, it would postpone the payment of dividends. He did not think the shareholders wanted dividends postponed, and as long as they could equitably transfer the cost of working an amount which had been expended in relation to improvements account, he thought they were entitled to do so. It was of no use to talk of attempting to carry on an electric light company without making improvements. If they decided on such a course, he, for one, would not continue the management of the Company. If they were to stand still, and simply sell what they had got, without adopting improved dynamos and improved manufacture generally, they would not succeed. Other companies had spent ten times the amount which had been spent by the Maxim-Weston Company. With reference to the stock, a considerable portion of that had been made in the first instance owing to his desire to obtain a large share of Admiralty work. What was necessary was that they should reduce the speed of their machine by 50 per cent. If they had undertaken that work then it would have cost them £5,000. After long correspondence the American Company undertook to manufacture a machine in terms of the requirements of the Admiralty contract. They got five of those machines, because the American Company would not make less, but when the machines arrived here they were condemned by the Admiralty, and the Company were left with them on their hands. Up till some time in 1886 the Company were almost entirely dependent for their dynamos upon America, but now, he was happy to say, they were almost entirely independent; and, in fact, he considered they were in a better position than the American Company to turn out a plant equal in candle-power to the American product at less cost, owing, of course, to the protective system which America adopted. With respect to the item of shares in the Electric Sun Company, he understood that there was a prospect of that company being reconstructed, as some improvements had been made in the old Sun lamp, and he was led to believe that the

Digitized by Google

item in the balance sheet of £239 would be more likely to turn out at £2,000. With regard to the item, orders, of £15,000, a considerable portion of that was for Government orders, and he hoped to receive in respect of them a very large cheque soon. As far as he could prognosticate the future, he felt satisfied that the reserve which they had made of £1,555 would amply cover any shortcomings which might come about in the realisation of that amount. In regard to the capital issued, it was a source of regret to him that the shareholders had applied only for a trifling amount of the last issue. The new money, in view of the improvements which they were making, would have been of great assistance to the Company. The Directors, however, had done their duty in the matter, and had subscribed in the proportion of ten times the sum found by the shareholders. The item of creditors and bills payable figured at £2,248 on the 31st December, but since then about £2,000 had been paid, so that the liabilities of the Company were of the most trifling character. With reference to the Watt patents, they were so designated out of courtesy to himself, and it was hardly necessary for him to say that others were interested in those patents, and some of the gentlemen he had had to buy out. The total sum he had spent in connection with those patents was from £2,000 to £3,000. They were originally offered to him, and as long as he was an official of the Company he would consider it his duty to give the Company the first offer of those patents, and as long as he remained with the Company they could manufacture them with no royalty. If the shareholders expressed a wish that the Maxim-Weston patents should be continued, the Directors would be speedily out of court in attempting to sell them against the existing competition. He did not think that in a public meeting like that it would be to the interests of the Company to state specially the relative cost of manufacture as between the Weston and Watt patents. The Company had not been involved in any expenses connected with the Watt patents beyond their having obtained the right of manufacturing with a view to meet the requirements of the trade. At present they were engaged in the manufacture of two machines on entirely different lines. He had already referred to the requirements of the Admiralty. The working plans, which were drafted for him by an outsider, were being carried out, and they had been approved by certainly one of the most eminent Government electricians. He had every reason to believe, therefore, that they would secure for those patents an enormous sale at an early day. The expense of manufacturing the new dynamos was 50 per cent. less than that of the Weston, and looking at the present prices which the Government were paying, they would be able to compete at an immense saving as compared with what they could do under the Weston system. They were enabled by the new lamp to subdivide the arc light from 15,000 to 150 candle-power. He thought, therefore, they would be able to supersede to a very large extent incandescent lighting. Shortly after he had been appointed a Director of the Company the conclusion he arrived at was that they must minimise the weight of metal for the maximum of results, and, in relation to the incandescent electric light, that they must secure an indestructible filament. They were working on those lines. If they succeeded the Company would have every advantage in the matter of any discovery he or any of his friends might make. They had succeeded in the matter of the arc lamp, and if they succeeded in regard to the incandescent light then they would be well in the van of electric lighting enterprise. The Company could have the Watt system if they thought fit, which was 50 per cent. cheaper than the Weston, and it would give them all the requirements of an electrical company, and they would thus have to spare the Maxim and Weston patents. Recently others had been moving in the matter of supply companies, and whatever other systems might be, including the Watt, there was no one superior to the Weston for a supply company. They had ample plant in stock to lay down stations. He had an idea as to the formation of supply companies, and, if possible, of the formation of a parent supply company, giving to them on terms advantageous to the Company the Maxim-Weston patents. If they did that they would obtain great advantages. Unless they were supported the Board could hardly expect to carry out negotiations and financial arrangements with that object, but they were willing to do their part. The Company was not a sensational but a manufacturing one. They could take no onus upon themselves as to the market value of the stock, and he should say, looking at the circumstances of the Company, that their stock was never more valuable than it was that day. Looking at the position of the Company and the intrinsic merits of its patents, he had no hesitation in saying that, notwithstanding the fact that they could not pay a dividend, they were in a better position than they were ever in before.

Mr. GEORGE HOWELL, M.P., seconded the motion.

Mr. L. SWABY said he desired to move an amendment appointing a committee of investigation. He stated that he had not himself seen the report until the shareholders generally had seen it, and that instead of having made £1,555 profit, they had made a loss. He maintained that the report was not the report of the Directors, that Mr. Brown's resignation had not been properly accepted, that Mr. George Howell was not a Director of the Company, that the balance-sheet was a farce, and that he (the speaker) was not in any way responsible for either the report or balance sheet. He then read a long correspondence with the view of bearing out these statements.

Mr. Under-Sheriff BEARD supported the amendment. He did not, he said, agree with the Chairman that the details of expenditure should not appear. Why, he asked, should not the shareholders know what had been done with their money, and why should they not know what it had cost to earn the £1,555 profit?

Mr. GREIG also supported the amendment, and thought that with the competition they had to meet they ought to have an influential Board, and that there should be more of the mercantile element in it.

Mr. J. M. KLENCK hoped that the meeting would not be led away by what Mr. Swaby said. They were a trading company, and a great deal would depend on their action that day. He himself thought that the £1,555 could not cover the amount of £15,000 for debtors. They ought to know the position of the Company as to the Watt patents.

A SHAREHOLDER called attention to the increased amount appearing under the head of patents, and wanted to know if the whole of that money had been spent in improving the Maxim patents, or whether any part of it had been spent in improving the Watt patent, in which the Company were not interested.

Mr. JACKSON cordially supported the amendment. He thought the Chairman had been too sanguine.

A SHAREHOLDER, in supporting the amendment, thought the name of Mr. G. Howell should be submitted to the shareholders for election.

The CHAIRMAN, in reply, said that when the Company was reconstructed Mr. Swaby subscribed for 4,000 shares, but he believed that that gentleman was more than a year in paying for them. The Directors felt from time to time that it was not fair of them to meet a Director sitting on the Board who was in default of his payments. Time after time he himself advanced Mr. Swaby money, and ultimately took the balance of the shares off Mr. Swaby's hands, as the latter had given to the Company bills which he could not meet. Mr. Swaby resigned on a former occasion because he could not pay his calls. They could not forfeit the shares of a Director without some arrangement, and that was the reason why he (the speaker) had himself acquired 2,000 shares held by Mr. Swaby. He did not desire to do so, having himself such a large holding already, but he had done so in order to maintain the honour and reputation of the Board. Before, however, he took those shares Mr. Swaby had sold them.

Mr. SWABY emphatically denied that statement.

The CHAIRMAN said that Mr. Brown resigned his position because he was unwell, as was also his wife, who had since died. For the year 1887 £500 was paid for Directors' fees, but he (the Chairman) had not participated in the payment. The reason that Mr. Swaby was not allowed to have a report and balance-sheet in the office was this, that he had charged Mr. Swaby from time to time with divulging matters affecting the interests of the Company, and it was a fact also that Mr. Swaby's brother-in-law had effected a partnership with a man who had done more to damage the Company than any living individual.

Mr. SWABY wanted to know what he had to do with what his brother-in-law had done.

The CHAIRMAN said that the Maxim-Weston Company was what he himself had made it. From time to time he had to find money for the Company to go on with, and he had had many sleepless nights in connection with it. With regard to the Watt patents, they were not originally his inspiration. They were brought to him, and he had paid cash in connection with them in order that the Company might have the advantage of them. But those patents were at the Company's disposal at the lowest possible price. The previous reserve account was absorbed up to 1886. It was specially stated that it was against bad debts, depreciation, &c. The Board were most willing at all times not only to have a committee, but they were anxious to have the assistance of every individual shareholder. He had always courted inquiry by the shareholders, and he could be seen at the office of the Company any day between 10 and 4 o'clock. He would have no objection to a friendly committee consisting of three or four gentlemen, if they liked to adjourn the meeting. He had intended to defray the cost of Mr. Howell's services out of his own pocket. (A VOICE: That won't do.) He saw no reason why the accounts should not be passed as presented, for the Committee could only deal with matters affecting the future.

Mr. JOHN NEWTON said that he had intended to support the amendment; but after the Chairman's statement it was impossible for him to do so. He, himself, had not doubted the existence of a reserve, but it was called by another name—balance of profit and loss account—and it would now be transferred to the reserve. He wished to support the Chairman in charging to capital all the money they spent in developments and improvements. If they did not do that they would have to reduce their 5s. shares to 2s. 6d.

Mr. HOWELL said, with regard to his election, that Mr. Watt had told him that he was in some difficulty in getting on with the work of the Board, and asked him (the speaker) to consent to act until the general meeting, which was held almost immediately—as it was held that day.

After some further discussion, the motion for the adoption of the report and accounts was agreed to with six dissentients, it being decided not to dispose of the remainder of the business on that occasion.

The following resolution was then submitted to the meeting, being drafted by the solicitor to the Company:—

"*That a committee of five be appointed to confer with the Directors as to the affairs of the Company, three to form a quorum, and that they do report to an adjourned meeting to be held this day four weeks, on the 25th April, 1888, at the same time and place.*"

The resolution was carried, and subsequently Mr. J. Newton, Mr. J. M. Klenck, Mr. G. H. Hildyard, Mr. John Marks, and Mr. Henry Alfred Greig, were elected the committee.

The CHAIRMAN, in reply to a question, said that he took it that the committee was formed to go into the affairs of the Company. He did not see what it would have to do with the private affairs of any one. Of course, anything in relation to his, or Mr. Swaby's affairs having an influence upon, or reference to the Company, must be considered, but nothing outside that.

On the motion of Mr. JACKSON, seconded by Mr. KLENCK, a vote of thanks was passed to the Chairman, and the meeting separated.

THE INFLUENCE OF LIGHT UPON THE ELECTROSTATIC CHARGES.

The phenomena recently discovered by M. Hertz, with regard to the action of the rays of higher refrangibility upon the static discharge (see *Electrician*, February 3rd, p. 324) has led M. Hallwachs to try if an analogous effect would be produced upon a charged body. A well-insulated disc of zinc was connected to a gold-leaf electrometer, and a negative charge was communicated to it. In front of the disc was placed a metallic screen, having a window of glass, through which a beam of light from an arc lamp was thrown. As soon as the light falls upon the charged body it is found that the gold leaves rapidly fall together, and at the end of about 10 seconds the disc has entirely lost its charge. If the disc is charged with positive electricity the loss of charge proceeds at a very much slower rate, and the author remarks that in this case it is probable that the effect is due to some other cause. The rapidity of the discharge is independent of the thickness of the glass plate, but it is diminished when we replace this by a plate of quartz, rock salt, or felspar. If the screen is made of cardboard or of paper the phenomenon is not observed at all. On analysing the beam it is found, as might have been anticipated, that the violet and ultra-violet rays are chiefly concerned, whilst the ultra-red rays produce no effect whatever. These results are quite concordant with those of MM. Hertz, Wiedemann and Ebert. The nature of the charged body has a considerable influence; for iron the dissipation of charge is much slower than for zinc, and for aluminium it is slowest of all. A difference is also observed when the surface of the metal is polished. This leads to the supposition that a modification of the surface is produced by the ultra-violet rays.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 17th*, 1888.

New York has long maintained a sceptical frame of mind as to reports reaching it of blizzards in the West; but its extraordinary experiences on Monday last have brought it into a condition of humble belief. The rain storm beginning on Sunday night changed suddenly into a raging snow storm, the snow being peculiarly hard and fine, and by daybreak on Monday the streets were already covered with a foot or two. As morning advanced the condition of affairs became worse. The snow, flung at New York by a wind whose velocity reached fifty miles an hour, soon filled up the streets and stopped every single street railway. This would not have been so serious had the elevated roads remained active, but by noon, owing to snow blockades, breakdowns, and collisions, the traffic on these roads was also stopped. Thousands of people were kept waiting for hours in the air in the cold trains between stations, and at last had to reach the level of the street by walking the slippery track or by climbing down ladders. The state of the city grew worse from minute to minute, vehicles of all kinds were abandoned in the streets, and it was not until the afternoon that any sort of relief came, when, during a little lull in the storm, a few trains moved along the elevated road again. Hundreds and hundreds of merchants and clerks who reached their offices down town were compelled to stay there all night, and many of the large stores—some of which, by strange irony, were celebrating that day their "spring opening"—were compelled to accommodate for the night those of their *employés* who had managed to reach their doors. All outside communication with the outer world was cut off, as the overhead telegraph and telephone wires broke in every direction. Scores of trains were waiting three or four days to get into or leave the railroad depots in and around New York, and none of the passengers were able to communicate with their friends. On Monday night, owing to the number of breaks and crosses, it was deemed prudent not to run the regular electric light service, and as the gas was also out in a great many places, the terribly dismal appearance of things can be imagined. All this week the wires of all the various electric services have been in a state of chaos, the telegraph and telephone being the last to get back into anything approaching their former shape. Not only the wires but the poles went, and the wreckage is more complete in this city and for miles around than it has been any time since the great storm of 1876. It is but natural that this event, with its practically total stoppage of traffic and communication, should provoke some very strong talk as to the desirability of underground wires and an underground railway. That a great many more wires will be put underground as the result of this experience cannot be doubted, but it is to be feared that we may have yet to wait a little time before we get the underground road in place of, or even as an addition to, the unseemly elevated structures. When the underground road does, however, become an accomplished fact, I believe that it will be operated by electricity. It deserves note, while on this topic, that our first news from Boston came in *via* England. We are still without through telegraph wires to Boston—only about 200 miles—but the splendid long-distance telephone lines are in use.

The public generally are awaiting with a good deal of interest the production of Mr. Edison's improved phonograph, which has been promised for some time past, and is now said to be ready for the market. A few changes have been made in the machine, but to all intents and purposes it is practically the same as when Mr. Edison created such a tremendous and world-wide sensation with it in 1876. Despite the distraction of his thoughts and efforts to the electric light and other matters, Mr. Edison has from time to time harked back to this invention, towards which he has a feeling almost affectionate, and upon which he bases some very sanguine expectations. Before long, the little wax cylinders which Mr. Edison now uses in place of the old tin-foil will probably be familiar objects, and there are many speculations as to the extent to which the phonograph will invade business life and become the rival of the typewriter and the skilled stenographer. For my own part, knowing what I do of the phonograph, I do not ever expect to see it supplant the human stenographer in the higher ranges of verbatim reporting, but I do think that in many departments, where the work is slow and of a routine character, the phonograph will find its place, and a large one. Of this, however, you will be able to judge for yourself when you see the latest instruments. I hear that one of them is to be shown soon at the Electric Club here by Mr. E. T. Gilliland, and that the factory at Bloomfield has a capacity of about twenty-five complete instruments a day. Meantime, however, the Graphophone Company, based on the patents of Prof. Bell and Mr. Tainter, have not been idle. It is even said that there are to-day in New York 200 graphophones ready for sale. This looks like a conflict in the courts at no very distant date, as there is not much to distinguish between the two instruments. One interesting little application of the phonograph is that of its use in talking dolls. A company, in which Dr. Jaques, of the American Bell Telephone Company, is interested, has been organised in Boston, and is now experimenting with dolls which have phonographs in their little insides, and which, when the machines are set in motion, talk and sing.

Now that so great an interest is taken in the subject of currents of high E.M.F. and their danger, it will interest many of your readers to know that Mr. Wood, the electrician of the American Company, has just built a dynamo which produces a current of 6·8 amperes, at 4,100 volts, for lamps to give 1,200 candle-power. The use of currents of such high voltage necessarily involves very good line construction, and undoubtedly complicates the problem of putting the arc light wires underground.

I believe I have already informed you of the fact that the subject of execution by electricity is now being actively debated in Massachusetts, which in the matter of social reforms never likes to play second fiddle to New York. There, as here, great difference of opinion exists. It is interesting to note that at the meeting of the Society of Medical Jurisprudence, held here a few days ago, the late report of the State Commission

Digitized by Google

was brought up for discussion, and after quite a lively and interesting debate a resolution was adopted almost unanimously against the Bill now before the State Legislature providing for execution by electricity. The doctors were not in any instance influenced by sentiment, or by the idea that electricity is degraded by being used as a means of punishment.

I find among telephone men the prevalence of the belief that the Supreme Court of the United States will hand down its decision in the telephone suits next Monday. The reason for this is that the Court then reassembles after a brief vacation, which is usually given to the writing of decisions. It is, of course, probable that the anxious public will once more be doomed to disappointment, but if a decision is rendered you will undoubtedly hear of it by cable before this letter reaches you. The parent telephone company in Boston is pursuing the even tenor of its way and a few more infringers.

While you abroad are discussing the transformer from the scientific point of view, the discussion on this side seems at present confined to the commercial aspect, and the first of a series of papers on the subject of continuous *versus* alternating current from this standpoint in particular was read this week before the Chicago Electric Club by Mr. H. Ward Leonard. Mr. Leonard's paper was entitled "The Comparative Value of the Continuous and Alternating Current Systems for the Commercial Distribution of Electricity," and he decided in favour of the continuous current. Mr. Leonard, in considering the value of the two systems, compared them with each other on the following points, namely, first cost, economy, efficiency, depreciation, reliability, variety and value of the possible sources of revenue, safety of life, and effects on existing property. Naturally, first cost and economy occupied the principal part of the paper. On the latter point Mr. Leonard showed that assuming the highest efficiency claimed for the alternating current generator, and assuming the generator efficiency as equal to that of a continuous-current generator under condition of partial load, and the converter efficiency to be the same at all loads, the three-wire system, with a maximum loss of 20 per cent. in the feeders, has as high an efficiency as the converter system, and in addition the three-wire system, as usually installed, with a maximum of 10 per cent. loss in conductors, has an efficiency of from 4 to 12 per cent. superior to that of the alternating-current converter system. Taking up next the question of first cost, Mr. Leonard has reduced everything to the cost per lamp for various lengths of feeders, and he has endeavoured to show that if the three-wire system be operated at an average efficiency of 92 per cent. in the feeder—which corresponds to the highest efficiency claimed for the alternating-current converter system—the total cost per lamp would be equal when the average length of feeder was 6,000ft.; and, according to Mr. Leonard, an average length of feeder of 6,000ft. corresponds to a circular area 18,000ft. in diameter, or about 3½ miles. With 94 per cent. efficiency in the feeders, the point at which the three-wire system is cheaper for lamps than the alternating-current system is 4,750ft.; and even with an efficiency of 96 per cent. in the feeder, or an average loss of 4 per cent., the conductors of the three-wire system are shown to be cheaper than the conductors and converters of the alternating-current system for an average length of feeder of 3,600ft. or less.

But Mr. Leonard held that if, as was more than probable, the voltage of the incandescent lamp would be doubled, and its economy increased 25 per cent., then, with the highest efficiency in the feeders—that is, 96 per cent.—the three-wire system would be the cheaper for cases where average distance of lamps is 8,000ft. or less. Treating also on the question of depreciation, Mr. Leonard maintained that the elements of depreciation in the converter system were far greater than in the direct current, and he cited as a comparison the value of copper conductors 20 years hence which cost $1,000 to-day, as against $1,000 worth of converters having small highly insulated wires. On the score of reliability, Mr. Leonard doubted the possibility of continuous operation of a system which thus far is still operating in single units, each dynamo feeding its individual circuit. Without the possibility of multiple arcing the machines at the station, Mr. Leonard holds that the system is open to serious drawbacks. Regarding the variety and value of the possible sources of revenue to be drawn from the two systems, the old arguments in favour of the continuous current are advanced, such as that the revenue from power distribution, from lamps and charge of storage batteries, &c., while obtainable with the continuous current, is impracticable with the alternating; and while the continuous current can be applied to all these, the alternating is necessarily limited thus far to the production of light, and possibly heat, only. The question of safety to life was also touched upon, and the dangerous character of the alternating and the harmlessness of the low-potential continuous current were dwelt upon. This paper will probably be followed by another in which the other side of the question will be taken up, and we may expect some interesting rejoinders.

TELEPHONE AND TELEGRAPH PROJECTS IN SCANDINAVIA.

(From our Stockholm Correspondent.)

There is no capital in Europe which can boast a more perfect telephonic arrangement than Stockholm, which also, if I am not mistaken, has the largest percentage of subscribers of any European town. Negotiations are at present pending for an amalgamation of the Stockholm General Telephone Company with the Telephone Company of Gothenburg, on the opposite side of Sweden. The Stockholm Telephone Company has offered to take over the one at Gothenburg, with buildings, wires, appliances, &c., and to substitute phosphor bronze wires instead of the steel wires now used, and telephones from L. M Ericson and Co., Stockholm, instead of those hitherto used, and to supply the station with multiple tables of best and newest construction, against each member obtaining one-third of a share in the General Telephone Company, Stockholm, the nominal value of each share being 300kr. The proposed terms for subscribers in Gothenburg under the new management are (per annum):—

A. For use of a telephone with own line to the central station.
   (*a*) If the subscriber is a member of the present company, and uses his old telephone, 70kr.
   (*b*) If one of L. M. Ericson's telephones is used, 80kr.

B. For use of a telephone in connection with double automatic exchange, 60kr.

The agreement should hold for five years, and commence on October 1st, 1888.

Should this proposal be accepted, there is every likelihood of the two towns before long being brought in telephonic connection, and that Gothenburg will also be connected with those towns that are already in connection with Stockholm. The new arrangement would no doubt also be made to comprise an additional number of towns in middle and South Sweden.

The Stockholm Telephone Company have applied to the Government for permission to fix telephone wires along the ordinary roads between Stockholm and Jönköping, Jönköping and Gothenburg, and Jönköping and Malmö, partly by direct lines and partly, between Stockholm and Gothenburg, by a line which should comprise Nyköping, Norrköping, Linköping, with branches to Motala and Örebro, Jönköping and Boros. The project also comprises a line Stockholm-Gefle-Söderhamn-Hudiksvall and Sundsvall. The Government is to have the right to purchase under certain conditions. It is the intention to make quite a new departure, as far as Sweden is concerned, in connection with these lines, as double wires of copper will be used. Hitherto, single lines have been used everywhere, with a single exception, and the wires have been of iron, which can only suffice within comparatively narrow limits.

In Norway there are also several new telephone lines on the *tapis*, one being through the Guldbrands valley, where the inhabitants complain that their only connection with the outer world is a post every three weeks.

The Christiania Telephone Company had at the close of last year 1,670 subscribers, and the number of telephones under the company's control amounted to 1,812. The average number of conversations on a week day was 7,000—9,000, and on a Sunday or other holiday 500—800.

The General Stockholm Telephone Company has purchased the Jönköping Telephone Exchange erected by the firm of Brunius and Co., and it has at once been taken by the Stockholm Company. The Jönköping Telephone Company is seven years old, and has 67 subscribers, which number is likely to be doubled on account of the favourable conditions offered by the Stockholm General Telephone Company.

Digitized by Google

The proposed tax in Sweden of 10kr. on each telephone meets with a great deal of opposition from various parts of the country. and will in all probability not be carried.

The Swedish State Telegraphs have applied to the Government for their sanction of the charge for home telegrams being reduced to 50 öre (about 6½d.) for a message of ten words, and a charge of 5 öre for each additional word. In order to meet the anticipated decrease of profits—at least, in the first year—a grant of 100,000kr. has been asked for. The new charge is not intended to come into force till the beginning of next year.

CORRESPONDENCE.

ELECTRIC TRACTION: SERIES SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. W. Geipel gives an extract from the patent of Profs. Ayrton and Perry's of 1887. I have a copy of this, as well as of the same of 1883.

The words, "as we may employ a magnetic arrangement depending for its action not on the weight of the train, but on its magnetic mass," is not sufficient as description, even for a patent, and in what way Profs. Ayrton and Perry themselves at the time understood this Mr. Geipel may find in their 1883 patent, No. 2395, p. 19, to which I have before referred.

After my and Mr. Binswanger's invention it is possible to find in the above sentence quite another sense.

Further, the object of our invention is "*safety* conductors for *tramways*"—that is, to make possible the electric traction on town streets, to build tramway lines which do not interfere with the heaviest traffic, and not simply, as Mr. Geipel says, "evidently to overcome the difficulty of leakage in long lines." This, judging from their patents, Profs. Ayrton and Perry did not intend to make or succeed in making.

I have not yet read the lectures of Prof. Ayrton kindly mentioned by him in your paper of March 9th, and wishing to give always to others what is theirs, but to keep what is mine, I must know who is the owner of what. I hope Prof. Ayrton will be so kind as to send me a copy of his most exhaustive lectures, and thus help me to clear up the subject.

I will leave Mr. E. Bergholt, secretary to the Series Electrical Traction Syndicate (Limited), in his sweet dream as to the "points of contact," and advise, as a very interesting subject of investigation, the patents and proposals taken out and made before 1881. After careful study Mr. Bergholt will, I think, change his opinion, if it were only his private opinion.—Yours, &c., CHARLES POLLAK.

11, Rue Descartes, Paris, 21st March, 1888.

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We, in common with the author of the letter in your issue of 16th inst. on the above subject, feel exceedingly alarmed at the prospect that opens out before us now that another set of rules has been published. It would be difficult to arrange at the present stage of the industry any set of rules the following out of which could better guard against dangers arising from electric lighting than those which have been drawn up by Mr. Musgrave Heaphy. The writer has seen a number of installations both on the Continent and in the United States, with the result of feeling assured that work of this kind in England is infinitely superior to that carried out in other countries, and there can be no doubt that our comparative immunity from fire arises from the judicious enforcement of these regulations.

A number of installations in this kingdom, including one or two of the largest, have been carried out by us, always under the Phœnix Fire Office Rules, and in no single instance has an electrical fire occurred.

It must certainly be the experience of every contractor that there is no difficulty in obtaining the approbation of the authorities of installations conscientiously executed.

If we are to have several sets of rules, it will be impossible to tender for work without a specification, and this means an expensive item added to the price of electrical work for the services of a consulting electrical engineer in each case, whose presence is unnecessary when a duly qualified fire inspector fills the position, free of cost to the proposed user of the electric light.

We do think that this is a matter for the leading contracting firms to interest themselves in, and their verdict goes almost without saying.

To frame and impose rules, it is necessary to have a "status": what is the "status" of those who are seeking to introduce the new ones, and what authority have they to handle a matter which so seriously affects the trade without first consulting it?

The matter is such a serious one that we trust more *direct and public impeachment* will quickly ensue.—Yours, &c, "INSTALLERS."

London, March 22nd, 1888.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We are in the throes of a new Electric Lighting Act, and expect its passing to open up an era of prosperity for the electric industry in this country, when at the outset irresponsible parties throw the apple of discord amongst us.

Do these "new rule" concoctors pay for fire damages or the fire offices? And how do they suppose to overcome the refusal on the part of any fire office to take a risk? If an installation is put up in accordance with their rules, I take it that the fire offices are agreed as to the value of the Phœnix Rules, and are content to take risks if the work is carried out in accordance with them.

I have always found every disposition on the part of Mr. Heaphy to look at any necessary modification of these rules in a broad manner, provided good reasons for deviating without risk could be shown.

There ought to be no difficulty in settling this interference. Let each contractor ignore the existence of these new rules, and we shall soon hear no more of them.—Yours, &c,

E. A. PARIS.

Gothic Works, King-street, Norwich, March 23, 1888.

THE PERCENTAGE ACCURACY OF WATTMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a review of "Le Wattmètre et son Maniement," which appeared in *The Electrician* of March 16th, there is an oversight in the calculation of the coefficient K which expresses the ratio of the reading on the wattmeter to the true watts in the circuit. There should be a factor, r, in the second term of the numerator, and a factor, r', in the second term of the denominator of the second expression given for K, and the omission of these vitiates the subsequent algebraical formulæ, though the results obtained are correct in their general characters. In particular, K instead of 1·5, comes out to be about 129 in the case considered, and the error, if reckoned as a percentage upon the true watts, is somewhat appalling.

It would perhaps hardly have been necessary to point out this correction if there were nothing more to be said, for a 50 per cent. error would be generally considered quite large enough to condemn an instrument, and I should merely appear to be slaying the slain; but it seems to me that a number obtained in this way is misleading to the last degree, and gives no clue whatever to the extent of accuracy which we may expect from the instrument when used as it always would be in practice.

Prof. Ayrton's formula is obtained on the assumption that all the power which we want to measure is spent in the heating of the circuit due to its resistance—that is, that there is no loss due to Foucault currents, or to hysteresis, or, which is most important of all, to the effect of mutual induction between the circuit and any other, and it is only applicable when these conditions hold. For example, when measuring the power given to a transformer, it can only be an approximation to the truth when the secondary is open. In this case, however, the power given to the primary will be only a very small fraction of its normal amount, which, I take it, is what a wattmeter is in practice designed to measure, and

Digitized by Google

an error which is unimportant compared with the latter may at first sight seem formidable when expressed as a percentage of the power.

In the same way if a wattmeter be used to measure the power given to a lamp circuit in which the lamps may be replaced by impedance coils, it may be quite possible that when all the lamps are out the indicated watts may differ from the true watts by a quantity large compared with the latter, and yet negligible compared with the watts when the normal number of lamps are alight.

I do not for one moment wish to be understood as defending the relation between self-induction and resistance given by Messrs. Ganz; indeed, I think ·02 ohm seconds an enormous self-induction for a resistance of only 250 ohms, and one which could not fail to introduce in practice errors which would be far from unimportant; but what I desire to point out is that a true criterion of what may be expected from a wattmeter is not in general furnished by Prof. Ayrton's formula, and can only be obtained when the uses to which it is intended to put the instrument are specified.

I have had occasion to devote a good deal of time to this subject, and the conclusion to which I have come is that it is quite impossible to design any wattmeter depending upon electromagnetic attraction which will measure with good percentage accuracy the power in a circuit when the difference between the phases of current and E.M.F. is nearly 90°, but that in all other cases the construction of suitable instruments presents no other difficulties than those of mechanical detail. The accurate determination of activities, which are small, while both the current and E.M.F. are large, is, however, only needed in research and testing work, where the other well-known methods of measuring power are applicable; and with this the wattmeter as a commercial instrument is not required, fortunately for itself, to have anything to do.—Yours, &c.,

March 28, 1888. L. R. WILBERFORCE.

PRODUCING OXYGEN GAS BY ELECTROLYSIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you kindly say what is the lowest cost oxygen can be produced by electrical decomposition of water, stating means used; also, would an ordinary low-tension dynamo produce 1,000 cubic feet per day, or what plant would be required? Your kindness will oblige.—Yours, &c., B. W. SMITH.

Smethwick, 21st March, 1888.

[In reply to our correspondent's inquiry, we may say at once that the electrolytic production of oxygen cannot compete as a commercial process with other well-known methods. Brins' process, or even the ordinary oxide of manganese and chlorate of potash process, will be found less costly. The following calculation of the expenditure of energy required to produce 1,000 cubic feet of oxygen by electrolysis of water will probably, however, enable our correspondent to form his own opinion as to the value of the process:—

1,000 cubic feet = 28,420 litres.

1 litre of oxygen at standard pressure and temperature weighs 1·4298 gramme.

1,000 cubic feet of oxygen therefore weighs about 40,600 grammes.

The electro-chemical equivalent of oxygen is ·000084; that is to say, a current of one ampere will in one second liberate a weight of oxygen equal to ·000084 gramme.

The liberation of 1,000 cubic feet of oxygen will therefore require $\frac{40{,}600}{\cdot 000084} = 483{,}333{,}000$ coulombs, or 134,250 ampere-hours. Now, including losses in leads, &c., it will be safe to take 3 volts as the E.M.F. required per cell. Hence the expenditure of energy is given by

$$\frac{3 \times 134250}{746} = 540 \text{ horse-power-hours, electrical.}$$

Assuming a day of twelve hours, this represents the output of a dynamo machine of 45 electrical horse-power, which is equivalent, say, to 65 indicated horse-power from the engine. Our correspondent can easily make his own calculation as to the cost of energy from this point from his local knowledge; but if we assume the value of an indicated horse-power-hour as 1½d. we should have £4. 17s. 6d. per 1,000 cubic feet. This figure, it must be remembered, only takes account of the actual cost of energy consumed; we shall be happy to give our correspondent any further assistance in our power.—ED. *E.*]

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

COMPANIES' MEETINGS & REPORTS.

The Direct Spanish Telegraph Company (Limited).

The twenty-ninth ordinary general meeting was held at Winchester House, Old Broad-street, last Monday, under the presidency of Sir James Anderson.

The MANAGER (Mr. C. Gerhardi) read the notice calling the meeting, and the minutes of the last meeting, which were approved and signed by the Chairman as correct.

The CHAIRMAN: Gentleman—I suppose we will take the report as read (hear, hear). On reading it over carefully myself again, I must say that I find very little to add to it. It is a very neat report, very short, and yet it conveys everything that I can think of worth saying. You will notice in the second paragraph that our traffic has increased by £1,338, notwithstanding the fact that on the Barcelona section the traffic has fallen off, owing to the absence of speculation. The increased traffic we have obtained is therefore due to other parts of Spain. I may further add that in the first three months of the present year there is a further improvement in the traffic of about £250—that is taking into account the estimated revenue for the Easter week, which is always a small one. I hope, therefore, that for the present year we shall get up to 5 per cent. dividend on the ordinary shares. It only requires £600 to pay us 1 per cent., and I do not see why we should not get to that amount of dividend by-and-bye—I hope more, because the trade of Spain is evidently taking a start. It required no less than 181,000 additional words to make up that increase in our traffic of £1,338 in the last half year. What, however, pleases me more than anything else is the last paragraph in the report, where you find that over £8,000 stands to the credit of the reserve fund. Of that amount £5,000 is invested in Forth Bridge Railway Four per Cent. Debenture Stock, and Liverpool Corporation 3½ per Cent. Stock, and the value of that investment has increased by £250 since we bought it. I hope next time we meet we shall be able to show in our accounts our investments on account of reserve, as is customary in other companies. I told you at the last meeting, I think, that we were getting a direct wire from Madrid to Bilbao. It is not quite finished, but I hope when we get it the traffic will still further improve, because nothing more increases telegraphic communication than the rapidity and accuracy of transmission. Our average time now from Bilbao to London is only five minutes, leaving, I think, nothing to be desired; but if we can get a special wire to Madrid, we may get through messages in five or seven minutes to Madrid; then I think we should have a further improvement in our traffic. I do not think there is anything more to tell you unless you ask questions. The Company is prosperous. We are working at a very low tariff, as I stated at our last meeting, and yet we are increasing our revenue. Last time I had to tell you that the traffic had fallen off for the previous three months. Now I have to tell you that it is increasing, and but for the Easter week, which Mr. Gerhardi has estimated in the three months' revenue, we should have had ½ per cent. more dividend already earned, a fact which, to my mind, is altogether satisfactory. We should get a little more reserve, and pay away the revenue to the hilt, and the Direct Spanish will then compare with any telegraph company in London. With these remarks I beg to move

"*That the report and accounts now presented be, and they are, hereby received and adopted.*"

Mr. ETLINGER: I beg to second that.

Mr. DYETT asked for an explanation of the item in Abstract 3, "Stationery, including Morse bands, &c."

The CHAIRMAN, in reply, said the Morse bands were the tapes on which the signals from the instruments are recorded. They used an immense number of these bands. And with regard to the stationery, that naturally increased with the growth of the traffic.

Mr. DYETT then referred to the item of unclaimed dividends, and asked whether the Secretary did all he could to reduce that amount, and get the money paid to those to whom it belonged.

Mr. JOHN NEWTON asked whether it was necessary to put £5,000 to the reserve fund.

The CHAIRMAN: Yes, that is a settled matter, and I would resign rather than that it should be interfered with.

Mr. NEWTON thought it was quite right if it was understood, and it made the Company stronger. Still, the amount was large compared with the reserve fund held by other companies.

The CHAIRMAN: It was part of the agreement. We put it before the Court.

Mr. NEWTON said that it of course made the Company stronger. The time would come when they would have such a strong reserve that they would have to issue bonus shares.

The CHAIRMAN: You must remember that our debentures are terminable.

Mr. NEWTON thought it very satisfactory to see a large fund accumulating. For his own part he would not be sorry to see the item of unclaimed dividends increase still further. If the persons to whom the sums belonged had left the country or were dead, and their executors did not care to claim the amount, the Company must have the benefit of it. He thought it was a mistake to put the item in the report at all. It was as much an outstanding liability to creditors as any item they had in the balance-sheet, and it should appear as that.

Mr. DYETT said he did not agree with Mr. Newton as to the unclaimed dividends. The money did not belong to the Company, and any neglect in paying it over to the parties to whom it belonged ought to be avoided.

The CHAIRMAN: But we have great difficulty sometimes in finding out to whom the money belongs. We do all we can to give notice that we have these dividends in our possession.

He then put the motion, and it was carried unanimously.

The CHAIRMAN next proposed

"*That a dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend of 2¼ per cent. for the half-year on the ordinary shares, free of income tax, be and are hereby declared.*"

Mr. ETLINGER seconded the motion, which was carried unanimously.

On the motion of Mr. ETLINGER, seconded by Mr. J. D. PENDER, Sir James Anderson was unanimously re-elected a Director.

Sir JAMES ANDERSON proposed, and Mr. J. DENISON PENDER seconded, the re-election of Mr. Etlinger as a Director, which was carried unanimously.

Mr. BARNETT then proposed the re-election as auditor of Mr. Herbert R. Duke, remarking that the remuneration of that gentleman was very

Digitized by Google

small, being only ten guineas. He thought the Board might consider whether the amount could not be increased.

Mr. ETLINGER said it was entirely a shareholders' question.

The resolution was then carried, it being agreed to raise the amount to fifteen guineas.

Mr. NEWTON proposed a vote of thanks to the Chairman, by whose efforts, he said, the Company had been brought to a living condition, a fact which the Chairman and his colleagues might be congratulated upon.

Mr. C. BURT seconded the motion, which was carried *nem. con.*

The CHAIRMAN: In the name of my colleagues and myself I thank you. As to one remark of Mr. Newton about the large reserve—we make our debentures terminable, and when that happy time comes, we may use some of the reserve, and if I had my own way, I would call up the remaining £1 per share. That, however, is a long way off; but we may as well pay ourselves 6 per cent. as the debenture holders.

Mr. NEWTON inquired when the debentures terminated.

The CHAIRMAN: In May, 1894. In further reply to Mr. Newton and Mr. Dyett, he stated that they could not pay off the debentures before that date without giving a premium. They could only pay them off by agreement. Until they had a much larger reserve the matter did not seem to press.

Mr. DYETT suggested that the £1 a share should be called up.

The CHAIRMAN: Well, that would be £13,000, and if you had £7,000 of reserve to add to it, it would go some way towards covering the amount required.

The proceedings then terminated.

China and Japan Telephone Company (Limited).

The following is the report of the Directors of this Company for the year ended the 31st December last, presented at the fifth ordinary general meeting of the Company, held at the registered office of the Company, 14, Austin Friars, in the City of London, E.C., on Monday last:—

The revenue account, after having been charged with debenture interest, and a sum of £122. 13s. 7d. having been written off in respect of depreciation, together with a sum of £108. 10s. 8d. in reduction of preliminary expenses, shows a balance of £642. 10s. 3d. at credit.

This amount has been carried to profit and loss, and finally wipes out the balance of £419. 6s. 7d. still standing at debit of that account, and leaves a surplus of £223. 3s. 8d. to be carried forward, which the Directors regard as eminently satisfactory.

The exchange at Hong Kong was re-opened in January of last year, and now numbers some fifty subscribers. It is hoped that with a good and continuous day and night service, which is now being given, the public will be more ready to lend its support to the Company, and that the present year may see further additions to the number of subscribers

The subscribers to the Shanghai Exchange have again reached the numbers at which they stood before the advance in the rate of subscription was made, as alluded to in last year's report, and an encouraging feature of the year has been the acquisition of several Chinese firms to the exchanges.

Considerable progress in the extension of both the telegraph and telephone systems appears to be taking place throughout China, and when the Chinese begin to thoroughly understand and appreciate the advantages of the telephone, both from a business and social point of view, the Directors look for an extension of the Company's exchanges, both at Shanghai and Hong Kong.

A good demand has existed for telephonic instruments and electrical material from outports, and fair profits have been realised from sales. Owing, however, to competition from various quarters, these have latterly been much reduced.

The Director who retires at the present meeting is Mr. Thomas Lloyd, but being eligible he offers himself for re-election.

Messrs. Price, Waterhouse and Co., the auditors, also retire, and offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 23rd amounted to £5,094.

GLOBE TELEGRAPH COMPANY.—The directors of this company have declared the payment of an interim dividend on the preference shares of 3s., less income-tax, and of 2s. on the ordinary shares, the income-tax having already been deducted, payable on the 18th proximo, for the quarter ending April 18th, 1888.

THE SCHANSCHIEFF BATTERY COMPANY.—The prospectus is issued of the Schanschieff Electric Light and Power Company, with a capital of £200,000 in 40,000 £5 shares, of which the present is a first issue of 30,000 shares, of which 20,000 are offered to the public, the remaining 10,000 being taken by the vendor, together with £70,000 in cash or shares, at the directors' option, and half the amount arising from the sale of, or licenses to use, the patents in any countries except the United Kingdom, in payment for the patent rights. This company is formed to purchase from the Schanschieff Electric Battery Syndicate the patent rights for the United Kingdom, France, Belgium, Germany, Italy, United States of America, and India for the Schanschieff single-liquid battery, and also the benefit of applications for patents in respect of the invention, which have already been made by the vendors in many other countries, together with the right to patent the invention in all other countries in the world in which patents or similar rights can be obtained.—It is stated that the capital of the company has been over-subscribed.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 23rd, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,179.

NEW COMPANY REGISTERED.

THE JULIEN ELECTRIC COMPANY (LIMITED).—Registered by Walter Webb and Co., 23, Queen Victoria-street, London, E.C. Capital £100,000, divided into 10,000 shares of £10 each. Object, to purchase or otherwise acquire the British patents, viz., 1885, No. 8,881, improvements in secondary batteries, part of which is applicable to primary batteries; 1886, No. 2,470, for improvements in electrical locomotion, propulsion or traction, and the apparatus therefor; and also the benefit of an application for Letters Patent 1887, No. 8,855, for improvements in and appertaining to electric piles and plates therefor, and for such purpose to enter into and carry into effect the agreement referred to in the Article of Association, either in its present form or with or subject to such modifications as may be agreed upon, or to purchase or acquire the said patents, or any of them, or any interest therein upon other terms; to carry on the business of manufacturing or dealing in engines, machinery apparatus, rolling-stock, or other things which are manufactured or used in accordance with the said inventions. The first subscribers are:—

	Shares
A. W. Ripping, clerk, 9, Woodville-road, Mildmay-road, Islington, N.	1
R. R. P. Braithwaite, clerk, 56, Osnaburgh-street, Regent's-park, N.W.	1
A. F. Stokes, stationer, 5, Birchin-lane, E.C.	1
T. B. Weare, oil merchant, 50, Devonshire Chambers, Bishopsgate-street	1
A. Barton, clerk, 30, Malvern-road, Dalston, E.	1
R. Gordon, gentleman, Acacia grove, New Maldon, Surrey	1
A. G. Pavill, clerk, 2, Cavendish-terrace, Frant-road, Thornton Heath	1

The number of directors shall not be less than three nor more than nine, in addition to any managing director or directors. The first directors shall be appointed in writing by the subscribers to the Memorandum of Association. The qualification of a director shall be the holding of stock, shares or debentures of the company of the nominal amount of £200. The remuneration of the directors (other than the managing director) shall be a sum equal to £100 per annum for each director, with an additional £100 per annum for the chairman.

ELLIOTT BROTHERS,

101 & 102, ST. MARTIN'S LANE, LONDON, W.C.

TELEGRAPH ENGINEERS AND MANUFACTURERS OF ALL KINDS OF ELECTRICAL TESTING AND TELEGRAPH INSTRUMENTS.

Submarine Mining Apparatus, &c. Contractors to H.M. Government.

SOLE AGENTS FOR THE SUPPLY OF SIR WILLIAM THOMSON'S NEW STANDARD ELECTRIC INSTRUMENTS.

Telegraph Address—"OHM," LONDON. Telephone No. 3852.

F. GEERE HOWARD,

Electrical Engineer and Contractor for Wire Running of Every Description.

MANUFACTURER OF WOOD CASINGS

FOR ELECTRIC LIGHT CABLES AND WIRES OF ALL SIZES: Plain or Moulded, in every description of Wood.

CLEATS, SWITCH BOARDS, SWITCHES, CUT OUTS, &c.,

And every description of Woodwork for Electricians.

Price Lists and Quotations upon Application.

CLEVELAND WORKS, CLEVELAND ST. LONDON, W.

NALDER BROS.,

Instrument Makers, Electricians, and General Electrical and Mechanical Engineers,

WESTMINSTER ENGINEERING WORKS,

132, Horseferry-road, Westminster, S.W.

Manufacturers of Resistance Boxes, Wheatstone Bridges, Thomson and other Galvanometers, Lampstands and Scales, Electrometers, Condensers, Keys, and Electrical Standards of every description.

SOLE MAKERS OF PROF. GEORGE FORBES'S THERMO-GALVANOMETER.

VOLTMETERS and CURRENT INDICATORS.

Cathetometers, Micrometers, Bar Callipers, and all descriptions of Electrical, Physical, and Mathematical Instruments. Experimental work undertaken. Chloride of Silver and other Batteries. Switch Boards, Switches, and Electric Light Fittings

Instrument Cabinet Work.

Complete Installations of Electric Light undertaken Engines Dynamos, Motors, and Lamps supplied.

SOLE LONDON AGENTS FOR MESSRS. SULLIVAN & CO.'S CHROMIC ACID.

BROWNING'S ENAMEL PAINT,

FOR INSIDE OR OUTSIDE WORK.

Prepared to dry with an enamel surface, glossy and firm, or "flat." It has stood years of wear and washing in Drawing-rooms, Kitchens, Pantries, Basement Offices, and in Stables, Cattle Sheds, &c., especially on the brickwork of Stalls, where a hard and washable surface is essential.

It has been continuously used on the Houses of Parliament, the Eastern Telegraph Companies' system Lines of Steamers, on Gasworks, on Hospitals, such as St. George's, St. Thomas's, &c., &c., Warehousemen and Clerks' and other Schools, Bank of England, Hurlingham Club, Metropolitan Fire Brigade, Stock Exchange, and numerous other important public works.

The Enamel Paint requires no mixing, being sent out ready for use in any colour or tint.

The **INDESTRUCTIBLE PAINT** is prepared in three colours only, Bronze-Green, Chocolate, and Black. It resists the action of acids and alkalies.

BROWNING'S COLOURLESS PRESERVATIVE SOLUTION

Is a perfect cure for Damp Walls, makes bricks and porous stone weatherproof. It has preserved the finest architecture, marble and other monuments, and public buildings from decay. It was successfully applied to Cleopatra's Needle nine years ago, and "the best authorities consider that it will have the effect of thoroughly preserving the monolith for centuries yet to come."

The Paints and the Solution secured the highest awards at each of the exhibitions, Fisheries, Health, and Inventions.

Write for Prices and Full Particulars to the

INDESTRUCTIBLE PAINT COMPANY, 27, CANNON STREET, E.C.

FREDK. LACK and SON,

90, STRAND,

CONTRACTORS FOR SHIPS' LINEN & BEDDING.

ALSO FOR

Household and Cabin Furniture, Carpets, Linoleum, China, Cutlery, and Plate for Export.

TELEGRAPH STATIONS FURNISHED THROUGHOUT.

Contractors to the Telegraph Construction and Maintenance Company Eastern, Eastern Extension, Brazilian, and African Direct Telegraph Companies.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 516.—Vol. XX. FRIDAY, APRIL 6, 1888. Price 4d.

NOTES.

Although three judges dissented from the finding of the Court in the case of the American Bell Telephone Company, commented on in our leading article this week, it should be noticed that the dissent relates only to that part of the case with which Drawbaugh's alleged invention was concerned. On all the other points the Court seems to have been unanimous, and even on this the dissentient judges cast no doubt upon the independence of Bell's discovery, but are unable to dismiss the whole of Drawbaugh's witnesses as untrustworthy.

The language employed by Mr. Justice Bradley, however, in favour of Drawbaugh's claims is itself decisively against their legal validity. The following passage will sufficiently illustrate our meaning:—"He (Bell) was a man whose professional experience and whose scientific attainments enabled him to see at a glance the importance of it (the telephone). Drawbaugh was a different sort of man. He did not see it. Had he done so he would have taken measures to interest persons with him in it and have brought it out." According to our patent law the man who sees, and acts on what he sees, is alone entitled to a patent; and Drawbaugh in an English court could only have established his own claims by destroying his title to a patent, publicity and usage being fatal to exclusive rights.

But without reference to English patent law it is evident that except for Bell's successful discovery the world would never have heard anything of Drawbaugh's magneto telephone, supposing he ever invented one—which is supposing a great deal. It follows that we owe both the discovery and its application to Bell; to Drawbaugh we owe absolutely nothing. To transfer the ownership in the invention from Bell to Drawbaugh would therefore have been grossly unfair in any case; but to do so on the testimony of a parcel of ignorant villagers would have been absurd.

Some three months ago we stated that negotiations had been set on foot with a view to effect a re-amalgamation between the United Telephone Company and its various offshoots. Some progress has been made since then, and the *Financial News* of Wednesday last contained the following:—

"This is an age of grand amalgamations, and another is on the carpet. The various telephone companies are now negotiating for a fusion of interests. Being already very closely related, they should have no difficulty in drawing the cord still closer. So far the negotiations have proceeded very smoothly, and, though not yet completed, a successful issue to them may be confidently predicted. A good deal more is, we believe, contemplated than mere combination. Better working arrangements in the metropolitan area will be an essential part of the scheme. Another incidental reform will be a classification of the new capital adapted to various classes of investors. By putting so much in debentures and so much in preference shares, the return on the ordinary can be greatly increased, even on the basis of present revenue. There are, moreover, experienced telephone men who predict that a little more enterprise exhibited in certain directions would speedily increase the revenue by 50 per cent. at least. These are slight prognostications of a very big scheme, about which we may have more to tell shortly."

Under the title of "How They Do It in England," the New York *Electrical Review* publishes an interesting communication from "An Observer." As wise men we are all of us glad of an opportunity to see ourselves as others see us, so that no apology need be made for reprinting the following passages from this 'cute observer's criticism:—

"Quite an interesting tableau is presented to the quiet observer on a careful perusal of the proceedings of the English Society of Telegraph-Engineers, at their meeting of February 9th, 1888.

"First, Mr. Knapp (*sic*), a high electrical authority and cup bearer to the amber god, stood up loaded to the muzzle with core and shell transformers, whose differences and peculiarities he discussed in his usual forcible and logical methods. He told of the idiosyncrasies of the healthy adult transformer; and he gradually warmed up to the task of tackling the diseases, such as 'static hysteresis,' and 'viscous hysteresis,' and 'dissipated energy,' and magnetic resistance to good behaviour, &c. Altogether his paper was most interesting.

"Mr. Knapp stands, as it were, with one foot in direct-current territory, the other in the field of transformers, and reaches for safety fuses with both hands.

"Next comes our old acquaintance, Prof. Ayrton, the renowned maker of mysterious ammeters, voltmeters, ohmmeters, and a whole tribe of other meters, including everything but a common-sense meter, capable of being taken apart, repaired, and reliably calibrated by the owner. He wanders anxiously through the dark wilderness of instrumentation with the light of criticism, like Diogenes with his candle, looking for an honest meter. True to his instinct he *finds* it (Invenio: I come upon, I *invent*), and how beautifully simple and English it is, to be sure.

"Then, after a few scattering observations by eminent members of the society, the adjournment being at hand, Mr. Crompton fiercely satirises the previous remarks of the various

Digitized by Google

speakers, and notifies them that his gun, too, is loaded, and at the next meeting he proposes to demolish them with their transformers and blackboard mathematics from a purely commercial standpoint. At the reconvening of the society, the adiourned discussion was taken up, and the wreckers began their work. Mr. J. E. H. Gordon, the hitherto great champion of alternating-current direct distribution, thought it a great pity to see so much ingenuity lavished on that *ignis fatuus* of the electrical engineer—the transformer system—which, it is true, is of great scientific interest, but of no practical value, only intended for a makeshift, &c. He abandons his cherished theory about direct distribution, and comes out strongly in favour of distribution by storage batteries. Why? Because it does not pay to run a 20,000-light dynamo for twenty-four hours, when the whole number of lights is called for only during a few hours—say, 4 to 10 p.m. It is bad for the coal pile. Certainly, Mr. Gordon, but the conclusion does not form a necessary sequence that storage is the *summum bonum.* The arguments against 5,000 horse-power quadruple expansion engines are good, but why use them? Under Mr. Church's plan of lamp-hour-proportioned engines and dynamos, the argument fails.

"Finally, the great Crompton begins his work of demolition. With true British superciliousness he ridicules everything that everybody else asserts, runs down their efforts and results, and insists that they have a little to learn still in the way of electric lighting. He has 'carried out several central stations;' *ergo* he knows it all. Such egotism is only equalled by the taste displayed in the following remarks :—

"Anybody who has been to America, and knows anything about American installations, will corroborate me in saying that the electric light machinery as made in the shop is perfection, but the putting up of it is such as would not pass muster in the worst of our English installations. That has been the case with the transformers set up by Mr. Westinghouse, and though perfectly suitable for such countries as America and Australia, where rough workmanship and rough things do, they are quite unsuitable for a civilised town . . . ."

The letter concludes with some remarks which lead us to fear that the writer is not able to sufficiently discriminate the wheat from the chaff—unless, indeed, in his case it is all chaff. These are his concluding words :—

"But in all this there is a lesson for Americans. For years most of the scientific text-books have emanated from abroad. In the literature of electric lighting we have been largely accustomed to depend upon the supposed superior erudition of our English cousins, and to accept their theories, elucidations, and conclusions as final and correct. But the spectacle of inconsistency, recrimination, and disagreement in vital questions presented at the last meeting of the Society of Telegraph-Engineers and Electricians shatters our idol and opens our eyes to the species of idolatry we have been practising. After all, though we have read their books, studied their theories, and some of us have been misled by their conclusions, if our work is summed up for judgment, it must be said we are ahead. Our American electrician gets an idea, and he does not sit down for a week's wrestling match with sines and cosines, hyperbolic logarithms, or other mathematical sinuosities, but *goes to work* and reduces the idea to practical form, and thus makes more progress in one week than his English contemporary will in a year. Nor do our best electrical engineers waste their time in useless discussions in the domain of exalted mathematics as to whether or not such and such results can be accomplished by a formula with a 'constant' tacked to its tail, compelling a year's work to find the constant. They get there sooner with a footrule and T-square, but they get there just the same."

OUR esteemed contemporary *Engineering* has taken up a brief in favour of the installation rules just promulgated by the Guardian Fire Office and the Westminster Fire Office. We have nothing whatever to say against these rules, so far as their intrinsic merit is concerned; in fact, for the most part they might be taken as a condensed and abbreviated edition of the Phœnix Rules. Our contemporary is, however, inclined to value these rules chiefly on the ground of the absence of permissive clauses, and of all reference to the dispensing power of the inspector. This question is undoubtedly one of the most important and one of the most difficult which has to be dealt with, and the conflict of opinion upon the subject will certainly be very great. It is evidently quite impossible to frame a set of rules which shall provide for every possible contingency or condition which may arise in the whole field of electrical engineering, and we take it that even our contemporary will admit that any rules which aim at universal acceptance must in some way provide for circumstances of an exceptional character. The objection to the dispensory clauses in the Phœnix Fire Office Rules arises, we think, chiefly from the fact that their too frequent introduction imports an air of uncertainty and self-distrust to the whole set. Besides this, to a contractor who is inclined to scamp his work it opens up the possibility of getting a remission in the stringency of the regulations in places where, but for the appearance of the dispensory clause, it might never have occurred to him. It seems to us that the best plan would be to omit the references in the several clauses, and insert a final paragraph to the effect that whenever it is desired to make any departure from the strict letter of the rules special application must be made.

WE have already expressed regret that the subject of fire risks should have been still further complicated at a moment when the long-deferred report of the Committee of the Council of the Society of Telegraph-Engineers and Electricians is about to appear. Still more do we regret the uncompromising and even acrimonious tone which several of the disputants have seen fit to adopt. The question is, in fact, a difficult one, and a practical solution will only be obtained by a determined effort to arrive at an amicable understanding all round.

IT is comparatively easy to be wise after the event, but it may be none the less useful to remark that the present dissensions would probably never have arisen if the Council of the Society of Telegraph-Engineers and Electricians had seen fit to take the Members and Associates of the Society a little further into its confidence. A practical question such as that of fire risks, into which the commercial element so largely enters, might well have been discussed at a special meeting of the Society in committee of the whole house. This would have given every one concerned an opportunity of stating their own special views and opinions, and would no doubt

Digitized by Google

have led to the appointment of a sub-committee, consisting chiefly of the men whose interests were most nearly affected. There would then have been no excuse for saying that such a body of practical men, armed with the imprimatur of the Society, was not thoroughly competent to deal with the question, and also thoroughly representative of the industries affected. And there would probably have been little or no difficulty in arriving at an agreement jointly and severally with the Fire Insurance Offices. It is probably too late or too soon for this course to be adopted at the present time. But it is not clear in what other way a final solution can be arrived at.

WOULD it be unreasonable to suggest that the various Committees appointed by the Council of the Society of Telegraph-Engineers and Electricians should report progress at the Annual General Meeting of the Society? There are in existence at the present time, we believe, several Committees which have been appointed to deal with various subjects of considerable importance to the electrical world; of these we need only mention, besides the Fire Risks Committee, that on Standardising Instruments, and on Nomenclature and Notation. But with the exception of the first-named—which was itself at one time reported to have expired of inanition—nobody outside the Council has probably the least idea as to when, if ever, they may be expected to present a report. Many members of the Society are probably even unaware of their existence. Information on the subject may, for anything we know to the contrary, be obtainable on application to the ever-courteous Secretary of the Society; but seeing that the deliberations of these Committees frequently extend over years of, doubtless, arduous labour, we really think that it is due, no less to the Members of the Committees themselves than to the Society at large, that the progress of their deliberations should from time to time be made known. So long as no one knows either what Committees there are, who are on them, or what is being done, it is impossible to display as much gratitude, or even to feel as much confidence in the results of their labours as we naturally desire to do.

WE wonder whether the Nomenclature Committee has yet had under consideration the really important and pressing question of the desirability or non-desirability of the term "Magnetic-Resistance." Those who have to write much on technical matters would certainly feel thankful for an authoritative decision on this point; only if we are not to use this term we hope we shall be told what we are to use instead.

A REMARK of *The Times* correspondent with the Easter manœuvres, to the effect that there was always considerable danger of the opposing armies reading each other's flag signals, reminds us of a safeguard which perhaps we ought to have mentioned in our recent article on Electric Defences. There is, as we have said, an immense advantage in having a uniform code of signals, the Morse being on the whole the best, because most widely known. But for that very reason provision should be made against a time of war, when, although the alphabet remain the same, the words signalled shall mean something different, and be intelligible only to friends. A secret language of the kind here referred to has long existed in the navy; but we are not aware that the army is similarly provided, although for either flag signalling in face of the enemy, or electric signalling over country occupied or threatened by the enemy's scouts, a similar necessity for secresy would obviously arise.

WE were very pleased to hear Prof. Silvanus Thompson, at the last meeting of the Society of Telegraph-Engineers, speak so highly of Mr. F. C. Webb's little book on "Electric Induction." The book has been out of print for many years—we believe that only a very small edition was printed in the first instance—and we happen to know that as much as a guinea has been given recently for a copy. It was written some twenty-six years ago, and it is scarcely too much to say that the author was at least thirty years in advance of his age; we mean, of course, as measured by the average electrical knowledge of the profession.

Beziers (France).—The Gas Company of this town is about to supply an electric lighting installation for lighting the theatres.

The Welsh Gold Mines.—Electric lighting apparatus is now in course of erection at the gold mine at Gwynfynydd which is to be worked both night and day.

Postal Telegraph Appointment.—Mr. E. Ashton has been appointed Superintending Engineer of the Western District of Scotland in the place of Mr. Tansley, deceased.

Madrid.—On Saturday last the new regulations for the theatres of Madrid were published. The use of gas is entirely prohibited, and the adoption of the electric light within six months is made compulsory.

Tenders Required.—We would direct attention to the announcements of contracts for electric lighting *materiel* required at Bradford and Edinburgh, which will be found in our advertisement columns.

Edison versus Westinghouse.—The United States District Court at Pittsburg has given a "preliminary decision" in favour of the Westinghouse Electric Light Company in the suit brought by the Edison Company.

The "Ingeniero Civil"—We have received the first number of the *Ingeniero Civil*, of Buenos Ayres, a new fortnightly illustrated paper, which is to be the official organ of the Society of Civil Engineers of the Argentine Republic.

Lighting of the Suez Canal.—The Suez Canal is to be lit by means of compressed oil gas. The regulations concerning the electric lights to be carried by steamers in passing through the canal at night will remain in force as heretofore.

Cheltenham.—The special committee of the Cheltenham Town Council which has been appointed to draw up a report on the subject of electric lighting last week paid a visit to Taunton and inspected the Thomson-Houston installation in that town.

The Cornell University.—We have received a copy of the "Register for 1887-8" of this excellent institution at Ithaca, N.Y., giving a full account of the foundation of the University, its administration, equipment, and methods of teaching. The provision for electrical engineering students appears to be ample and appropriate.

Digitized by Google

Important Sale.—On the 17th, 18th, 19th, and 20th of April Messrs. Wheatley Kirk, Price and Goulty will sell by auction at Liverpool the whole of the iron and other buildings recently employed for the Exhibition, and also a large quantity of furniture, fixtures, timber, &c. Full particulars will be found in our advertising columns.

Barcelona Exhibition.—We are informed that the Anglo American Brush Electric Light Corporation have concluded a contract with the authorities of the Barcelona Exhibition for the erection and running of illuminated fountains similar to those which were an object of so much interest and attraction at the South Kensington Exhibitions.

Paris.—The firm of Mildé fils et Cie. has issued a circular which states that in view of the conditions imposed by the Municipal Council they are compelled to abandon their scheme for an electric lighting station in the districts of the Plaine Monceau and the Champs Elysées.—The first Thomson-Houston installation carried out in Paris, consisting of 30 arcs, will shortly commence work at an establishment in the Boulevard des Capucines.

Lighting Contract open at Konigsberg.—The British Consul at Königsberg announces that the municipal authorities of that town are advertising for tenders for the construction and maintenance of the necessary works for lighting the streets with the electric light. A copy of the conditions, with a plan of the city, can be obtained from the chief cashier of the municipality on payment of two and a-half marks, and tenders will be received until the 16th April next.

House Lighting.—The contract for lighting The Hawkhills, Easingwold, Yorkshire, the residence of Mr. J. H. Love, has been placed in the hands of the United Electrical Engineering Company (Limited). The installation will consist of about 200 16 candle-power lamps. The power will be supplied from a steam-engine and boiler to be erected by the contractor in a small engine-house built for the purpose, and a set of accumulators will be provided to keep 90 to 100 lamps running from eight to nine hours.

Copper.—*The Statist* has an interesting article on the demand for copper, enumerating four main sections—telegraphy, marine steam engines, locomotive engines, and brass fittings, &c. The conclusion appears to be warranted that the rise in the price of copper will almost certainly lead to the substitution of copper-coated iron for various purposes; but meanwhile the monthly deliveries of copper in France and England continued small during March, and stocks are accumulating on the hands of the syndicate.

Telephone Contract in Peru.—There are, we believe, no patent laws in Peru, but the Government has nevertheless decided to grant a concession for the exclusive rights to erect and maintain telephone lines and exchanges in that country for a period of fifteen years. The concession will be awarded to the contractor who offers to work at the lowest tariff for exchange communication. He will have permission to erect overhead lines, and to fix poles upon the roofs of the public edifices. Tenders will be received at Lima up to the 14th May.

The American Telephone Suits.—Our monthly contemporary, the *Electrical Engineer* of New York, has issued a special supplement containing a verbatim report of the judgment of the United States Supreme Court, delivered on the 19th ult. in the appeals against the Bell Telephone Patent, together with the opinion of the three judges who dissented from the views of the majority. We shall reprint this judgment, the first portion of which appears in another part of our present issue.

University College, Bristol.—The Students' Engineering Society of this College concluded the winter session on March 26th with a public disputation "On the Gas Engine *v.* the Steam Engine," and on March 27th with a *conversazione.* Mr. de Soyres occupied the chair on the first night, and Mr. Albert Fry on the second. The electrical and engineering exhibits attracted much attention, and a highly appreciated concert was rendered by the students and their friends. The proceedings were concluded by a short address to the departing members by Dr. Ryan, President of the Society.

The Conductivity of Boiling Sulphur.—M. Duter contributes to the *Comptes Rendus* a note in which he describes some experiments undertaken in order to see whether a current could be made to pass through sulphur maintained at the boiling point. He found that electrodes of platinum were attacked, and it was therefore necessary to use pure gold. By the aid of a copper voltameter placed in series he measured the number of coulombs passed through by means of a Ruhmkorff coil and a set of Leyden jars. At the end of eight hours he found that the increase of weight of the copper cathode was equivalent to the passage of a current of 0·0008 ampere. The specific resistance was not, however, ascertained.

Recent Improvements in Telephony.—The fortnightly meeting of the East of Scotland Engineering Association was held last Tuesday. Mr. A. R. Bennet, M.S.T.E. and E., of the National Telephone Company, read a Paper "On Some Recent Improvements in Telephony." After describing the duplex and quadruplex systems of telegraphy, Mr. Bennet showed that by an extension of the same methods applied to telephones the conveyance of two independent and simultaneous messages over the same wires, either in the same or opposite directions, was possible, and that without impairing the efficiency of the speaking. The Paper was profusely illustrated with diagrams and apparatus. Mr. Bennet received a cordial vote of thanks for his Paper.

Postal Telegraph Revenue.—The Revenue Returns for the financial year ended 31st March, 1888, show a continued increase of the receipts derived from the telegraph service. For the quarter ending June 30, 1887, the gross revenue amounted to £465,000, against £425,000 for the corresponding period in 1886. For the September quarter they were £540,000, the same quarter in 1886 yielding £515,000. The quarter ending 31st December, 1887, produced £465,000, as compared with £445,000 in the same quarter of 1886. For the fourth quarter just ended the receipts were £480,000, those for the corresponding period of 1887 being £445,000. Thus the total for 1887-8 was £1,950,000, against £1,830,000 for 1886-7, being an increase of £120,000.

Leamington.—Owing to the dissatisfaction expressed at the electric lighting on the Parade at Leamington, further alterations and improvements are about to be introduced by the Midland Electric Lighting Company. It is proposed to substitute, in place of the 16 candle-power Swan lamps now in use, 32 candle-power Edison lamps, and to reduce the number of lamp-posts by about one half. An alteration is also to be effected in the mode of hanging the lamps, which will not be suspended from the end of a long arm, but will be enclosed in a globe placed on the top of the supporting column. The globe will be 2ft. in diameter; the upper part opal, and the lower part frosted glass. The shape of the lamp will thus be hidden, and only the light coming from the globe on all sides will be seen.

Digitized by Google

Prize Offered by the Belgian Society of Electricians.—The Belgian Society of Eletricians offers a prize of 250fr. for the best essay on the elementary principles of electricity. The competition is open to anyone who is employed in the electrical industries, but is intended primarily for operators or mechanics, and not for those who have received a technical education. Algebraic formulæ are not to be employed, but may be given in a separate appendix. In general the demonstration of the fundamental laws need not be given, and the science of magnetism is not to be entered upon any further than is necessary for the explanation of electro-magnetism. The essays must be written in French, and will be received up to January 1st, 1889; further information may be obtained from M. E. Lagrange, Secretary to the Society, 26, Rue Vilain XIII., Brussels.

The "Phil. Mag."—The following electrical papers will be found in the *Philosophical Magazine* for April:—"Note on the Electromotive Force in Moving Conductors," by H. W. Watson; Experiments on Electrolysis—Part I. "Change of Density of the Electrolyte at the Electrodes," by W. W. Haldane Gee, B.Sc., Assistant Lecturer in Physics, and H. Holden, B.Sc., Bishop Berkley Fellow in Physics, of the Owens College, Manchester; "On a Modified Water-Dropping Influence Machine," by Prof. Silvanus P. Thompson, D.Sc.; "The Effect of Magnetisation on the Thermo-Electrical and other Physical Properties of Bismuth," by Herbert Tomlinson, B.A.; "On a Method of Determining the Difference between the Phase of Two Harmonic Currents of Electricity having the Same Period," by Thomas H. Blakesley, M.A.; "On Some Electrical Phenomena Provoked by Radiation," by Prof. A. Righi.

The Proposed Electric Lighting of Exeter.—At the meeting of the Exeter Town Council last week a memorial in favour of lighting the streets of the city by electricity was presented by a deputation from a public meeting held on the 21st ult., at which a resolution was passed to the effect that, "in view of the great satisfaction given by the recent lighting of the streets of Exeter by electricity, it would be in the interests of the city, and add to its attractiveness and prosperity if the principal streets were lit with the system of arc lighting now in use"—the Thomson-Houston. The memorial, to which no less than 3,000 signatures were appended, was referred to a committee of the whole council, as was also a letter from Mr. H. W. Michelmore, secretary of the Exeter Electric Light Company, notifying the intention of the directors to submit a tender for lighting the principal streets of the city by electricity, and incidentally mentioning that the system was as cheap as gas.

The Alleged Electrical Fire at Lucerne.—Some further particulars are now to hand concerning the destruction by fire of the Gütsch Hotel at Lucerne, which was at first rumoured to have been due to the electric light installation. At the inquest which has since been held it was, however, conclusively shown that this was not the case; although the transformer was supplied with fusible cut-outs, yet the lamps were burning as usual half-an-hour after the outbreak. Local opinion never endorsed the rumour, which only appeared in journals published at a distance. Other hotel keepers in the town who are using the electric light are quite satisfied that the fire was not due to this cause. The inquiry did not throw much light on the true origin of the disaster, though it is believed that a plumber who was at work on the roof the night before had something to do with it. The proprietor of the Central Station at Lucerne since the date of the fire has ordered a third dynamo from MM. Ganz and Co., of Buda-Pesth.

Electric Lighting of Trains.—A number of gentlemen interested in the lighting of railway carriages electrically, on the invitation of Mr. John Noble, general manager of the Midland Railway Company, have recently visited their works at Derby, to witness the working between that town and Manchester of the system of electric lighting of railway carriages designed by Mr. J. A. Timmis. The chief feature of the system is that it secures "through lighting" in a train by the adoption of the Union battery stored in each vehicle, and by this means any carriage may be put into a siding, or be slipped from a train, without interfering with the maintenance of the light. In case one or more of the vehicles are slipped or break loose from a train, the lamps in them, if lit, remain lighted, and if they are not lit provision is made for their being automatically lighted up. The London and Brighton Railway Company have now 15 trains lighted by electricity, two running between London and Brighton, the 13 others being local ones.

A Strike the Result of Bad Lighting.—A strike has recently occurred among the operatives at the textile manufactory of Tarpassa, in Catalonia. The Barcelona correspondent of the Madrid paper, *El Imparcial*, has been investigating the case on the spot, and he writes that the difficulties arose owing to the fact that the Alcalde and sanitary inspectors, having visited one of the factories, ordered the suspension of work owing to the very bad quality of the gas, and the consequent unhealthy condition of the rooms. The quality of the gas having been improved, and work resumed, the manufacturers imposed a condition on the workpeople to make up for the hours lost during the time the factory was closed, or else that there should be a deduction from the wages. The workpeople objected to this, and the difficulty led to a general strike. If the quality of gas employed on the Continent is so very impure that the sanitary authorities have to interfere, surely there ought to be not only plenty of scope for the introduction of the electric light, but every facility offered to induce engineers to supply the want.

Electric Coal-Cutting Machine.—The application of an electric motor to coal-cutting machinery has been carried out by Messrs. Bower, Blackburn and Mori, of Woodlesford. The framework or bed-plate of the machine is supported on wheels. Within the framework is mounted or applied the electric motor, which may be of any suitable construction. A rotary motion is transmitted to the shaft carrying the cutter bar through gearing. The lower part of the framework forms a circular turntable, and is fitted so as to be capable of a rotary movement on the bed-plate, this rotary movement being effected by means of a worm, mounted on a shaft, supported in the bearing, attached to suitable brackets, mounted on the bed-plate, and worm-wheel segment, attached to the upper part of the framework. By this means the cutter bar can be moved along by the attendant as the coal is being cut, and the proper feed given thereto. Although by preference the motor is carried on or attached to the coal-cutting machine, it may of course be placed at any convenient distance therefrom, and motion transmitted from such motor to the machine by gearing.

Bradford.—The Electric Lighting Contracts.—The scheme to be submitted to the Bradford Town Council for the lighting of the borough by the electric light has been adopted by the Gas Committee of the Corporation. The plans, &c., have been prepared by Mr. J. N. Shoolbred, C.E., the electrical engineer to the Corporation, who has also had the assistance of Dr. Hopkinson as consulting engineer. The generating station, as previously stated, will be erected on a site in Bolton-road belong-

Digitized by Google

ing to the Corporation, and substantial buildings of stone will be erected. The motive power will be supplied by three Lancashire boilers, with Galloway tubes, and the boilers will have a working pressure of 140lb. to the square inch. There are to be three sets of steam dynamos, each of which will be driven direct by a separate engine of the inverted vertical type. The three dynamos will have an output of 85,400 watts each, the contractors guaranteeing a commercial efficiency of 75 per cent. The conductors will be encased in lead, and the covering will be both chemical and waterproof. The area of supply will be restricted at the outset to the central portions of the town, but provision is made for considerable extensions. Contracts for the necessary works are to be received up to the 25th prox., and it is thought their execution will be completed by the end of September next.

Southampton.—On the evening of Monday, the 26th ult., the Mayor and a strong body of the Corporation of Southampton visited the sanitary works at Chapel for the purpose of inspecting the installation of the electric light in connection with the destructor. The work has been carried out by Mr. A. J. Baron under the direction of Mr. W. B. G. Bennett, the borough surveyor. Mr. Bennett explained to the Mayor and members of the Corporation present the mode of working the destructor, and pointed out that the existing boilers and engines might be employed as a means of power for lighting a large area round the works with arc lamps, and the Guildhall, Hartley Institute, and the Audit House with incandescents. It was stated that a saving could be made to the ratepayers over the present cost of gas of upwards of £100 per annum, with an increased amount of light in the streets and buildings mentioned. The Mayor and Corporation were unanimous in their approval of the success of the trial, and the Chairman of the Special Works Committee was instructed at the last Council meeting to bring up a detailed report of the same on Wednesday next, when an important discussion will take place. As an outcome of the experiments Mr. Bennett has received numerous inquiries from the borough surveyors of other towns concerning the cost of the destructor, together with the working expenses, &c.

Stockholm.—Our correspondent writes:—"A series of interesting trials with electric light have recently taken place at Stockholm, and have given great satisfaction. The Stockholm Gasworks are about to erect a central electric station in the Swedish capital, and have solicited tenders from a number of foreign firms. They also received an offer from the well-known firm of Ganz and Co., Buda-Pesth, and as this system was entirely unknown in Sweden, the company offered to arrange for a trial at its own cost; and this has turned out so well that it has been allowed to go on for some time. There is every reason to expect that the system will be adopted in a great number of cases where there is a question of transmitting the electric light some considerable distance. Sweden seems to offer a very good field for this light, as there are a great many small and large towns where there is plenty of water-power within a feasible distance. At the experiments which have been going on in Stockholm the engine is placed at the gas works, and the total length of the wire is about 2,000 metres; the wire is 4-millimetre copper wire, and is fastened to poles. A couple of large restaurants are lighted by incandescent lamps, and two good-sized arc lamps are placed outside the Opera House. The installation has been effected by the firm of Luth and Roséu, Stockholm, the representatives of Ganz and Co. for Scandinavia."

City and Guilds of London Institute.—An elementary teachers' course of ten lectures and demonstrations in Experimental Physics will be given by Prof. W. E. Ayrton, F.R.S., at the Central Institution, Exhibition-road, S.W., on Saturdays from 10:30 to 12, commencing on Saturday, April 21st, 1888. The aim of this course will be to exemplify the *natural* mode of teaching experimental physics to young students, so that they may learn to grasp the fundamental physical laws and facts, and obtain an elementary working knowledge of the subject. The methods of teaching the various branches of physics found in ordinary text-books will not be followed, but instead, the method which leads the pupils to start from their every-day knowledge of the subject and examine into the laws governing physical phenomena. The importance of teaching *through* the laboratory work of the students themselves, and the possibility of this being done in the case of even quite elementary students, will be fully entered into, and will be illustrated by examples of the way such teaching may be practically carried out so as to impress the more important laws firmly on the students' minds. Methods of constructing comparatively *inexpensive* apparatus, but which, nevertheless, can be used for *quantitative* experimental work, will be treated of in detail. The importance also of designing lecture and laboratory apparatus in accordance with the most recent scientific knowledge, rather than as a representation of the historical apparatus found in text-books, will be fully pointed out.

The International Electrical Laboratory at Paris.—If the recent proposal to found an electrical laboratory in England, under the auspices of the State, and for public purposes, has not been taken up, the advantages of such an institution have, at least, been secured to France by the International Society of Electricians. A central laboratory of electricity has been inaugurated at Grenelle by means of the profits arising from the International Electrical Exhibition of 1881. The sum available amounted to 331,000fr., and was granted by the Minister of Posts and Telegraphs on condition that the interior direction of the laboratory should be in the hands of a telegraph engineer from the State Department of Posts and Telegraphs. The plans were looked after by a committee of ten members of the International Society of Electricians, under the presidency of the president of that body, and M. de Nerville was chosen as director. Additional money was subscribed, and gifts of apparatus were obtained from various manufacturers. The work of the laboratory is divided into two classes—measurements of precision and industrial tests. The former class comprises measurements of resistance, electromotive force, and so on; the latter, tests of cables, batteries, dynamos, and other technical applications. By-and-bye it is hoped that original researches will also be carried out in the laboratory. Pupils are admitted gratuitously according as there is room for them. The laboratory is a large building in the Place Saint Charles, Grenelle, and contains a great variety of apparatus and machines, from delicate experimental instruments to dynamos and motor engines of various kinds, gas and steam. It is, in fact, very well equipped for the work to be done, and with all the latest improvements. A photometric room for testing electric lamps is a special part of the establishment. Moreover, it is in contemplation to build a new and more extensive laboratory later on, when necessity requires it and experience has been gained. One of its principal functions will be the standardising of electrical apparatus so as to secure a uniform comparison of results throughout the country. We may add that a somewhat similar undertaking has been instituted in Brussels, and in all probability the example of France and Belgium will be followed in other countries.

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

(*Continued from page 504.*)

Having now seen how the fluctuation of current strength is related to that of the impressed E.M.F. under the conditions of a simple sine law of variation, we pass to the consideration of the measurement of the *power* taken up in such a case.

If the thin line curve in Fig. 28 represent the sinusoidal impressed E.M.F. and the thick white line the corresponding current in an inductive circuit, then at any instant the rate at which energy is being expended on the circuit is equal to the product of the ordinates P M, Q M, which at any point M represent the E.M.F. and current respectively. The mean rate of expenditure of energy, or the *mean power* or *activity* taken up in the circuit is then the mean of all such products taken at very

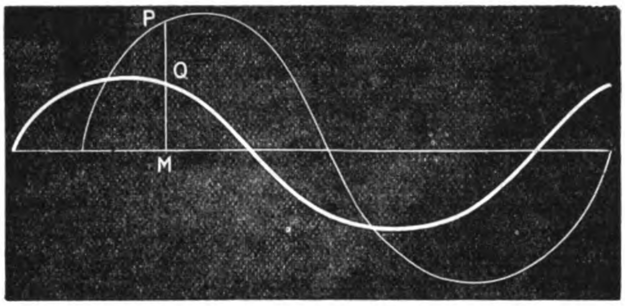

Fig. 28.

numerous and very near intervals. This is not by any means identical with the product of the mean current and mean electromotive force. To arrive at an expression for this mean power we must pave the way by a preliminary proposition on the mean product of two simple periodic quantities. An elegant geometrical proof of this has been given by Mr. Blakesley in his book "Alternating Currents," page 10, *Electrician* series. We shall, however, give here an algebraical proof of this proposition. Let there be two radii O P, O Q (Fig. 29) which revolve in equal periodic times round a common centre O, separated by a fixed angle, P O Q. At equal small intervals of time corresponding to equal angular motions let the projections O p, O q of these lines be taken on a vertical line through O. It is required to find the mean value of the product O p, O q during one complete period.

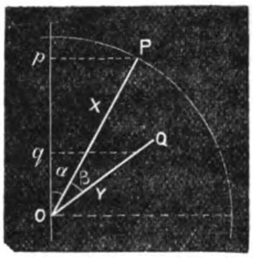

Fig. 29.

Denote by X the length of O P, and by Y the length of O Q, and let the angle P O Q be β, and P O p be α. β is the angle of phase difference, and X and Y are the maximum values of the periodic quantities O p, O q, which are the vertical projections of O P, O Q.

Let O p be denoted by p, and O q by q.

Then $\quad p = X \cos \alpha,$

and $\quad q = Y \cos (\alpha + \beta)$;

and therefore $\quad p\,q = X\,Y \cos \alpha \cos (\alpha + \beta).$

Let the pair of radii O P, O Q be supposed to turn round one complete revolution, proceeding by n jumps, each jump or step increasing the angle α by a very small amount, $\delta\alpha$, and n being a very large number. At each stage let the value of $p\,q$ be measured as above, then the mean value of the product $p\,q$ is one nth part of the sum of all the n values so taken. Call this mean value of the product M. Then,

$$M = \frac{XY}{n}\left\{ \begin{array}{l} \cos \beta + \cos \delta\alpha \cos (\delta\alpha + \beta) + \cos 2\,\delta\alpha \cos (2\,\delta\alpha + \beta) \\ \quad \ldots\ldots + \cos \overline{n-1}\,\delta\alpha \cos (\overline{n-1}\,\delta\alpha + \beta) \end{array} \right\}$$

By trigonometry we have

$$\cos (\overline{n-1}\,\delta\alpha) \cos (\overline{n-1}\,\delta\alpha + \beta) = \tfrac{1}{2} \cos (2\,\overline{n-1}\,\delta\alpha + \beta) + \tfrac{1}{2} \cos \beta,$$

since $\quad \cos \overline{A+B} + \cos \overline{A-B} = 2 \cos A \cos B.$

Accordingly every term, except the first in the cosine series for M, splits up into the sum of two others, one of which is always $\frac{1}{2} \cos \beta$. Rearranging the terms, we get for the value of M as follows :—

$$M = \frac{X\,Y}{n}\left[\tfrac{1}{2}\, n \cos \beta + \tfrac{1}{2}\left(\cos \beta + \cos (2\,\delta\alpha + \beta) + \cos (4\,\delta\alpha + \beta) \ldots\ldots + \cos (2\,\overline{n-1}\,\delta\alpha + \beta) \right) \right]$$

The cosine series in the inner bracket consists of a series of cosines of angles in arithmetic progression taken all round the circle. Hence, since the cosine of any angle is numerically equal to that of the cosine of its supplement, but of opposite sign, these cosine terms will cancel each other out pair and pair, when n becomes very great and $\delta\alpha$ very small, and $n\,\delta\alpha$ equal to $2\,\pi$. For when

$$n\,\delta\alpha = 2\,\pi,\ 2\,\overline{n-1}\,\delta\alpha + \beta = 4\,\pi + \beta, \text{ and } \cos (4\,\pi + \beta) = \cos \beta.$$

The first and last terms of the series are in this case indentical, and for every term there will exist one of equal magnitude and opposite sign. The sum of the series of cosine terms in the inner bracket is accordingly zero.

The value of M reduces them to that of the first term, viz. :—

$$M = \frac{X\,Y}{2} \cos \beta.$$

The mean value of the product of two simple harmonic or periodic functions of equal period but different amplitude and phase, is equal to half the product of their maximum values, and the cosine of the difference of phase.

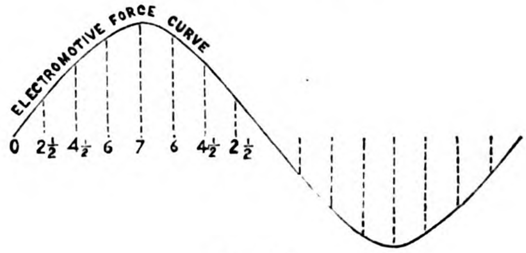

Fig. 30.

Returning to the consideration of the electrical problem, it is now clear that the mean value of the product of the current at any instant and the simultaneous value of the impressed electromotive force on an inductive circuit is obtained by multiplying together half the product of their maximum values, and the cosine of the angle of lag. If i be the current at any instant, and e the impressed E.M.F., I and E being their maximum values, then the mean value of $e\,i$ during a complete period is

$$\frac{E\,I}{2} \cos \theta,$$

and this is a measure of the rate of expenditure of energy on that circuit, or the work expended per second. It is obvious, then, that if the lag is 90°, this mean product is zero, and that no work is done at all.

When θ has intermediate values between 0° and 90° the real rate of dissipation or transformation of energy in the circuit will be intermediate between $\frac{E\,I}{2}$ and zero. In order to understand how this can be and how it is a circuit may be traversed by a current and yet take up no power we must examine a little more closely the nature of the phenomena.

Let the thin periodic curve in Fig. 30 represent a sinusoidal variation of electromotive acting on a circuit which we shall for

Digitized by Google

the moment assume has no sensible inductance. Let the thick curve in Fig. 31 represent the corresponding current. The length of each ordinate of the thick curve is equal in magnitude to that of the corresponding ordinate of the thin curve divided by the value of the resistance of the circuit. Let the lengths of corresponding ordinates of these two curves be multiplied together, and the product set off as the ordinates of a new curve represented by the dotted line in Fig. 32. This dotted curve is, then, the curve of *power* or *activity*, and represents the variation of the product, taken at every instant, of the current and the electromotive force.

In multiplying together the ordinates of the thick and thin curves we must pay attention to the algebraic sign of the factors. Ordinates of each curve drawn above the horizontal datum line of the curve must be reckoned *plus*, and ordinates drawn below must be reckoned *minus*, and in taking the product the algebraic law of signs must be regarded. It will then be seen that the dotted line curve consists of a wavy line of two loops lying wholly above the mean datum line. If the area of the two hummocks enclosed by the dotted curve and the

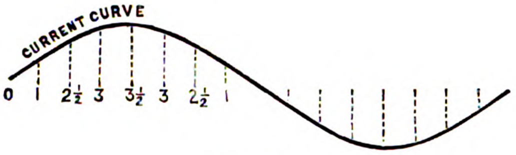

Fig. 31.

horizontal line is *indicated* or integrated, say, by an Amsler's planimeter, the area represented by the shaded part so obtained is a measure of the total work done in one complete period of the current oscillation, and since this area lies wholly above the datum line, it must be reckoned as *positive* or as work done by the electromotive force; in other

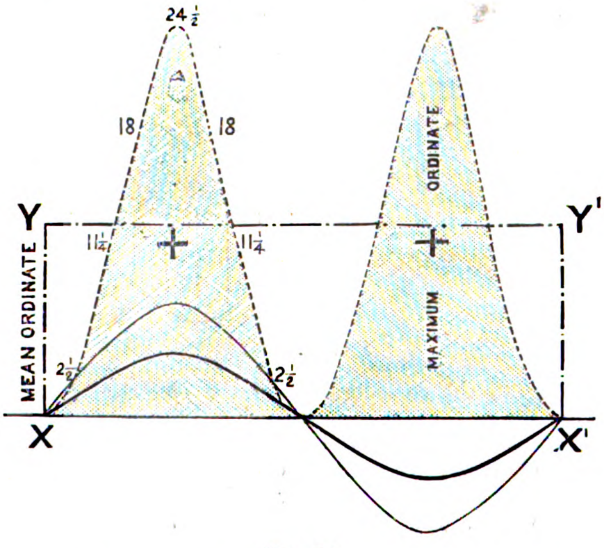

Fig. 32.

Ordinates.	Product.	Ordinates.	Product.
E × C	= P	7 × 3½	= 24½
0 × 0	= 0	6 × 3	= 18
2½ × 1	= 2½	4½ × 2½	= 11¼
4½ × 2½	= 11¼	2½ × 1	= 2½
6 × 3	= 18	0 × 0	= 0

words, it represents the total energy transformed from electrical energy into heat in one complete period.

Next let us suppose that the same periodic electromotive force acts upon a circuit having inductance as well as resistance, and that therefore, as before shown, the current is retarded in phase behind the electromotive force. Let the thin curve in Fig. 33 represent the periodic impressed electromotive force, and the thick curve the current retarded by 45° in phase behind the other. Proceed as before to obtain the power curve by multiplying the heights of corresponding ordinates, the multiplication of the eight ordinates being shown in the margin. We find, then, that the power curve representing the variation of the activity is a wavy curve, consisting of four sections, two large hummocks above the datum line, which are positive areas, and two small ones below, which are negative areas. The algebraic sum taken with regard to sign of all these four areas, represented by the shaded parts, is a measure of the total work done in one complete period by the electromotive force. Going one step more, we may imagine that the current lag is 90°, and in Fig. 34 we have drawn the

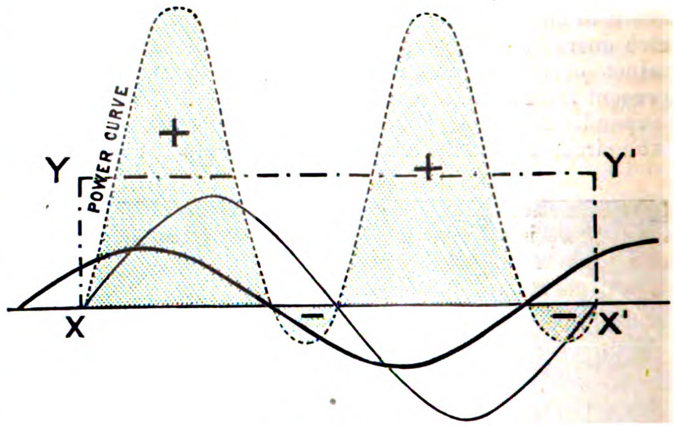

Fig. 33.

Ordinates.	Product.	Ordinates.	Product.
E × C	= P	7 × 2½	= 14½
0 × 2½	= 0	6 × 1	= 6
2½ × 3	= 7½	4½ × 0	= 0
4½ × 3½	= 15½	2½ × −1	= − 2½
6 × 3	= 18	0 × −2½	= 0

power curve in this case, obeying the same instructions. We see that the power curve consists of four loops, two positive and two negative, and that the areas of these hummocks are equal. Hence, the total area or *indicated* value in this last case is zero, and the work done in one complete cycle is zero; hence the rate of doing work, or the power, is zero. Returning to Fig. 32, the first case, it is easy to see that the rate of doing work, or the power, is measured by the *mean ordinate* of the shaded work areas considered as indicator

diagrams. Since the dotted curves are perfectly symmetrical, if we draw a line Y Y″ at half the height of the maximum ordinate of the dotted curve, it will cut the two hummocks into two parts, and the area of the upper part or mountain above the line Y Y′ would just fill up the valley between the bottom parts of the hummocks. Since the rate of doing work is equal to the work done in one complete cycle divided by the time of duration of that cycle it obviously follows that this mean ordinate X Y measures the power or rate of doing work and is equal in magnitude to $\frac{E\,I}{2}$, hence this product is a measure of

Digitized by Google

the rate at which the electromotive force does work. Referring to the second case, we see that the mean ordinate X Y is no longer equal to half the maximum ordinate of the positive or upper loop, but is equal to half the difference between the magnitudes of maximum ordinates of the positive and negative loops of the power curve, and is therefore less than $\frac{EI}{2}$. From the proof given previously, we have seen that it is equal to $\frac{EI}{2}$ (cosine of lag).

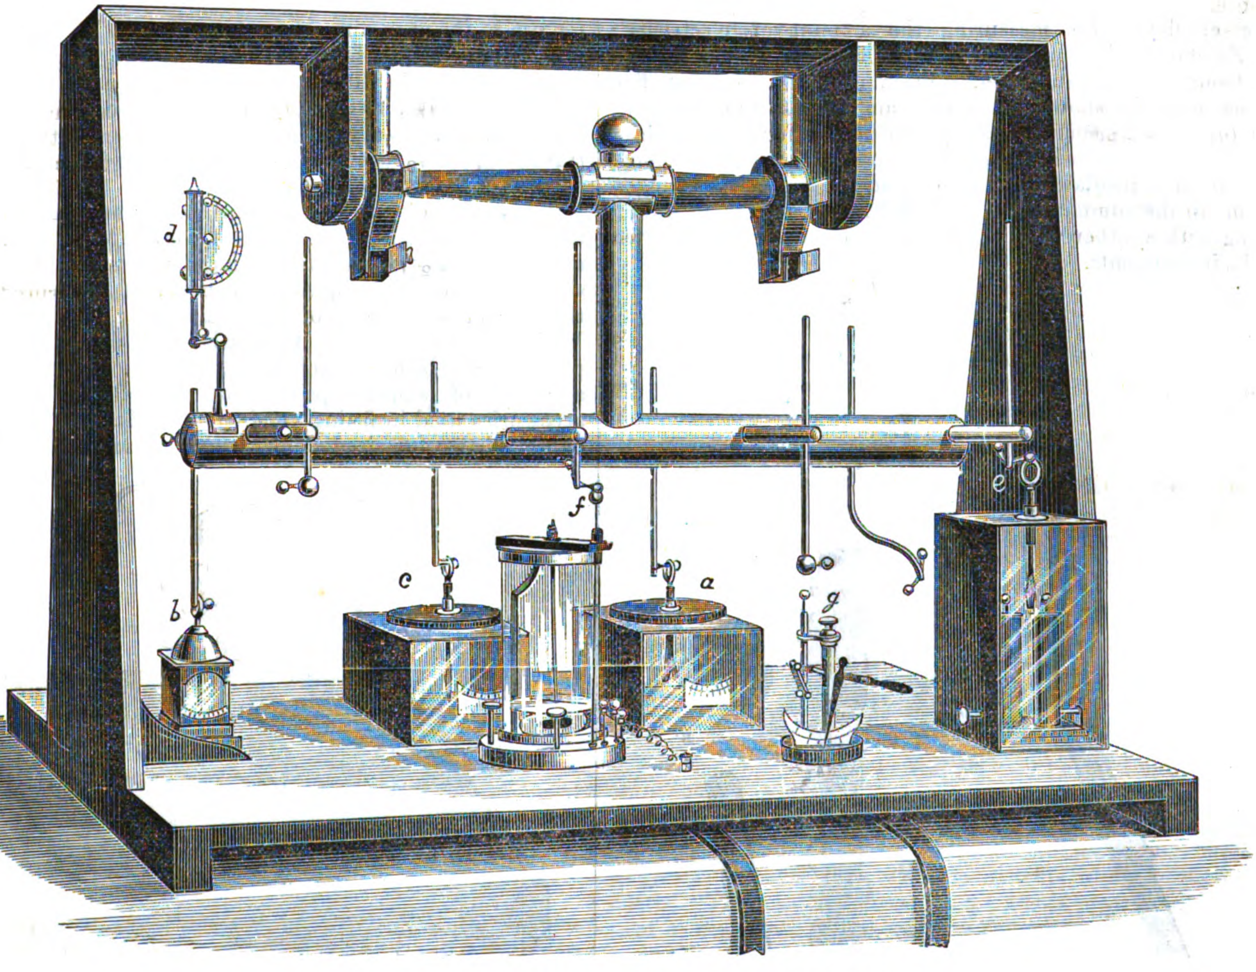
In the third case considered, of a lag of 90 degrees, it is easy to see why the resultant rate of doing work is zero. In the first *quarter of a stroke* the electromotive force propels the current, and this last is in the direction of the E.M.F., but in the second quarter of a stroke the current is negative or opposite to the electromotive force; in other words, the current is moving against the force and does work against the E.M.F., and the same push and re-push is repeated in the second half of the period. Hence, on the whole, though there is an impressed electromotive force and a current flowing, no resultant work is done and no energy dissipated. We may construct a mechanical analogy of this as follows:—

Imagine a steam engine with a heavy fly-wheel working without friction. Let steam be applied to it, the slide-valve being so set that it opens when the piston is at the bottom of the cylinder, and cuts off the steam after a very short fraction of a stroke. Suppose the valve then to remain closed for the rest of the stroke, and that instead of opening to exhaust the cylinder at the end of the stroke the valve remains closed, so that the momentum of the moving fly-wheel drives the piston back and compresses the steam back to its original volume. The valve then is supposed to open and permit the steam to escape at the same pressure at which it entered. Assuming no loss of heat (an altogether hypothetical case), we should then have an engine which absorbs at each stroke a cylinder full of steam; but by which no work is being done. The whole operation is a sort of give and take of energy between the fly-wheel and the steam. The same kind of action is taking place in a circuit acted upon by a simple periodic E.M.F. in which the inductive resistance is so large compared with the ohmic that the lag is 90°. In that case there is no frictional dissipation of energy, but simply a give and take of energy between magnetic field and the source of energy supplying the E.M.F.

(To be continued.)

THE ROYAL METEOROLOGICAL SOCIETY'S EXHIBITION.

BY WILLIAM MARRIOTT, F.R.MET.SOC.



THE ROYAL METEOROLOGICAL SOCIETY'S EXHIBITION.—FIG. 1.

The Royal Meteorological Society's ninth annual exhibition of instruments was held at the Institution of Civil Engineers, 25, Great George-street, Westminster, from March 20th to 23rd. The exhibition was devoted chiefly to instruments connected with atmospheric electricity, and was of a very interesting and popular character. This has been the most successful of the Society's annual exhibitions, and has been visited by many hundreds of persons. We propose in the present and succeeding articles to give our readers a brief account of some of the principal instruments exhibited.

The catalogue comprised 155 exhibits, which were grouped as follows:—Electrometers, lightning conductors, lightning pro

Digitized by Google

tectors for telegraph purposes, objects damaged by lightning, alleged thunderbolts, new instruments, photographs of flashes of lightning, and photographs, drawings, &c. The lightning conductors were set out in the Library of the Institution, while the other exhibits were arranged in the two adjoining rooms.

The Astronomer-Royal exhibited the electrical apparatus which was formerly in use at the Royal Observatory, Greenwich. The instruments were mounted on a stand, so as to show the manner in which they were actually arranged for observation (Fig. 1.). These consisted of (*a*) Bennet's gold leaf; Volta's (*b*) light and (*c*) heavy straw; and (*d*) Henley's electrometers, all of which were employed for measuring the amount of electricity; (*e*) Zamboni's dry piles, for showing the kind of electricity; (*f*) Gourjon's galvanometer, containing 2,400 coils of fine copper wire, for showing the kind and amount of electricity; and (*g*) Ronald's spark measurer, for measuring the length of sparks. The exploring copper wire, which was 400ft. long, and carefully insulated, extended from the roof of the Octagon Room to the summit of a mast 80ft. high, thence communicating with another wire, by which the electricity was carried to the instruments.

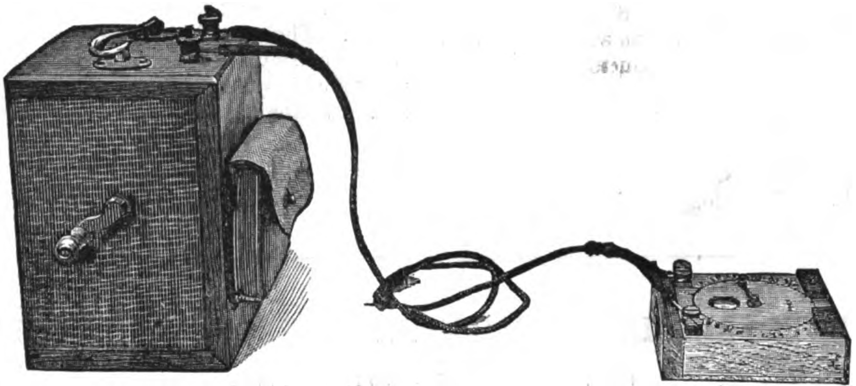


Fig. 2.

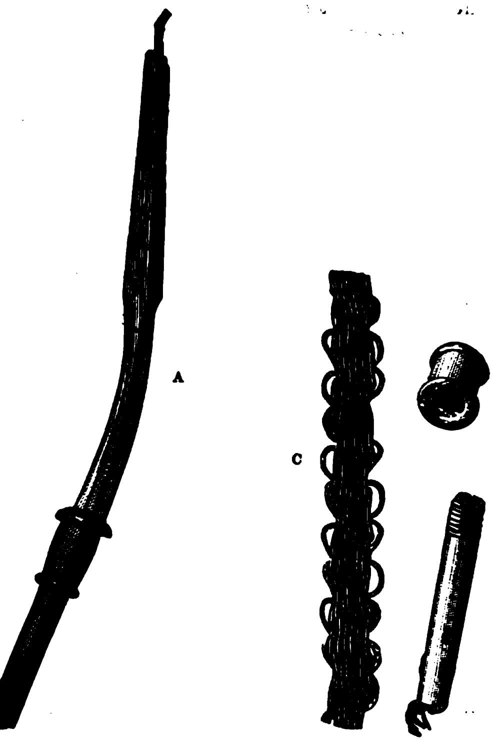

Fig. 3.

The instruments used by Sir Francis Ronalds in the Electrical Observatory maintained during his superintendence of the Kew Observatory, 1843-1851, were shown by the Kew Committee. These included :—Volta's electrometer with straws; Gourjon's galvanometer; various electrographs; Landriani's electrograph as constructed by Ronalds for recording the presence of electrical currents, by fixing powdered chalk in the resinous surface of a disc carried round by clockwork; two dry piles; Wheatstone's modification of Bennet's electrometer; Coulomb's balance; and a portable electrical observatory by Ronalds. A full description of these instruments, with illustrations, is given in the British Association Report for 1844. The Kew Committee also exhibited two forms of Sir William Thomson's portable electrometer, in which the electricity is collected by means of a burning fuse at the extremity of a vertical wire.

Prof. F. Exner, of Vienna, sent his portable apparatus for the observation of atmospheric electricity, which is intended for use in the open air and on journeys. This is a very compact arrangement, the chief parts being a leaf electroscope, gauged from 50 to 200 volts, a stick, with handle to screw on, inlaid with ebony to carry the collector, and the collector. If it should be necessary to calibrate the electroscope afresh while travelling, there are also provided a condenser and a small battery of twenty elements.

A very fine display of lightning conductors was arranged in the library. Messrs. J. W. Gray and Son and Messrs. R. Anderson and Co. exhibited models of churches, houses, and chimney shafts fitted up with lightning conductors in accordance with the recommendations of the Lightning Rod Conference. Various forms of upper terminals with one, three, or four points, some being nickel-plated, were shown, together with specimens of copper tape and rope, as well as all the various accessories used in fitting conductors. Messrs. Gray and Son exhibited two full-sized copper rings, about 5ft. in diameter,

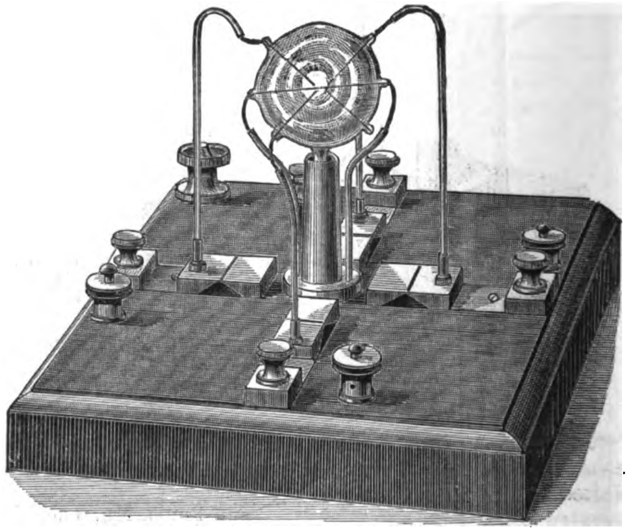

Fig. 4.

with four points to each, as used for factory chimneys; Messrs. Anderson and Co. a coil of copper tape 300ft. long, and Messrs. J. Davis and Son an earth plate consisting of a sheet of copper 3ft. by 2ft. by one-sixteenth of an inch.

Messrs. Siemens Brothers and Co. showed their lightning

Digitized by Google

rod testing apparatus, which consists of a magneto-inductor in combination with a testing board (Fig. 2). It is fitted with a galvanometer and other testing appliances, which are all contained in one portable case, and are capable of being used by persons who have no knowledge of electricity. By means of the inductor magneto-electric currents are sent through the lightning rod and earth connection, and the resistance of these is shown on the testing board. A resistance of more than 10 ohms would show that the conductor or earth connection is in such a state as to have become a positive danger, instead of a source of safety, to the building to which it is fixed.

Portions of several conductors damaged by lightning were exhibited, including three which had been sent to the Lightning Rod Conference. Fig. 3 gives a sketch of portions of the conductor which failed at Caterham on May 28, 1879. This shows the upper terminal *a*, the screwed union at which the conductor was fused, *b*, and a portion of the conductor *c*.

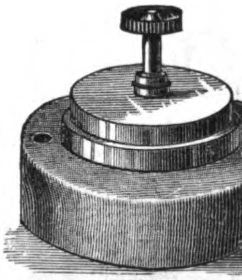

FIG. 5.

The Postal Telegraph Department sent various patterns of lightning protectors used for telegraph purposes. The earliest was Varley's Globe Vacuum Lightning Protector, which was used in 1861 (Fig. 4). A number of platinum points connected to the line-wire are arranged in close proximity to the end of a platinum wire connected to the earth, the whole being enclosed in a small glass globe (through which the wires pass, and into the sides of which the wires are sealed) exhausted of air. Siemens' Plate Protector used in 1865 consists of two corrugated cast-iron plates, the upper one being connected to the line and the lower one to earth. The plates are prevented from touching each other by their ebonite washers. The corrugations on the plates are so cut that those on the one plate are at right angles to those on the other. In the modern circular plate protector used in 1886 (Fig. 5) the plates, which are of small dimensions and circular in form, are separated by a thin sheet of mica, which has three circular perforations in it.

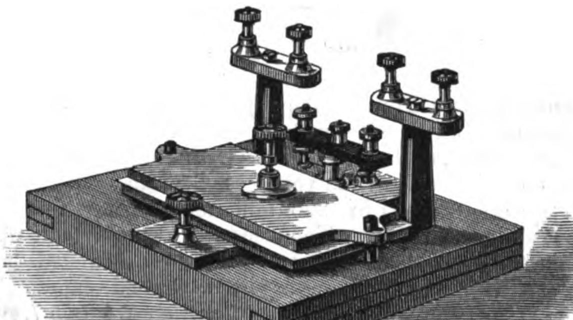

FIG. 6.

Two forms of cable protectors, which are used at the junction point of a submarine cable with a land line, were also exhibited. The earlier instrument, used in 1870, consists of a corrugated plate protector, and also of a silk-covered German silver wire, on circuit with the line, wound on a metal bobbin connected to earth, the whole being covered with paraffin wax to keep out moisture. The later instrument, in use since 1880 (Fig. 6), is similar to the preceding, but has the plates uncorrugated, experiment having proved that corrugations did not increase the efficiency of the arrangement.

(To be continued.)

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER VIII.—*The Calibration of Current Indicators.*

(Continued from page 567.)

100. *The "Calibration Constant" of a Tangent Galvanometer.*—The actual values of the currents on the tangent galvanometer are readily found when the deflection corresponding to one particular current is known, all the others following proportionally from that. For example, the tangent instrument in Fig. 56 requires a current of 2·43 milliamperes to deflect the needle 45 degrees. From this determination, which is easily made by passing a known current through the instrument, we may find the current C corresponding to any other deflection, say 60 degrees, by simple proportion :—

$$C : 2{\cdot}43 :: \tan 60 : \tan 45,$$

and since tan 45 is equal to unity

$$C = \tan 60 \times 2{\cdot}43 = 4{\cdot}21 \text{ milliamperes.}$$

Hence the tangent of any angle of deflection on this galvanometer, multiplied by 2·43, gives the current in milliamperes corresponding to that particular angle of deflection, and the number 2·43 is known as the "*calibration constant*" for this particular tangent instrument. Hence *the calibration constant of a tangent galvanometer is the number which, when multiplied by the tangent of the angle of deflection, gives the current passing, and this number is equal to the current which causes the needle to deflect to 45 degrees.* The values of the tangents of the various angles are found by reference to a table of tangents given at the end of most electrical text-books.

The calibration curve of the indicator may now be plotted in the usual manner, by marking off its angular deflections on the vertical ordinate, and the corresponding currents, determined on the tangent galvanometer as above, on the horizontal ordinate.

If the curve is taken with the object simply of having a record of the relation between currents and deflections, and it is not desired to have the actual values of the currents marked on the ordinate, all that is necessary is to mark out on the horizontal ordinate the tangents of the deflections on the tangent instrument and the corresponding angles of deflection on the indicator on the vertical ordinate. It should be borne in mind, however, that the curve is the same whether the actual values of the currents are determined or not. But it is such an evident advantage to have the actual current values, and so little extra trouble to determine them, that the methods for calibration which are here given include their determination.

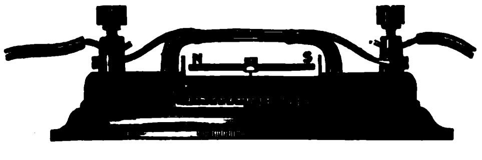

FIG. 58.

101. *Practical Example of Calibration by Comparison.*—In Fig. 58 is shown a current indicator for indicating currents of greater strength than with the instruments previously considered. The needle is shown at *n s*, and is pivotted on a point fixed in the centre of an ordinary compass box marked round in degrees. The coil is of rectangular shape, and consists of a few turns of No. 18 insulated copper wire, the lower half of the coil being let into the wood base. The curve determined for this instrument is shown in Fig. 59. Now, since the currents reach as high as one ampere and over, the cell used for the test and the tangent galvanometer used as an instrument of comparison must both be of low resistance, otherwise we shall not get sufficient current. For example, with one cell of two volts E.M.F. giving one ampere of current the total resistance of instruments and cell could not

exceed two ohms. Hence, the tangent galvanometer used was one with a thick wire coil of a few turns and very low resistance, the cell used was a secondary cell of about $\frac{1}{10}$th of an ohm, and an adjustable resistance frame containing spirals of No. 18 German-silver wire, by which the extra resistance in the circuit could be adjusted from one to twelve ohms, was also included in the circuit. As mentioned above, the actual resistances in the circuit are not taken into account, since the tangent instrument gives the values of the currents. The readings taken were as follows:—

Angles of deflection on indicator.	Currents on tangent galvanometer.
82	1·69 amperes
78	1·3 „
76	1·05 „
74	·92 „
69	·67 „
58	·39 „
37·5	·14 „

From these observations the curve in Fig. 59 is plotted, and as it presented a resemblance to a tangent curve in general form, the writer has worked out a few values for the true tangent curve shown by the dotted lines, by which the wide difference which would be anticipated between this instrument and a true tangent can be seen. To do this, one point on the curve must be taken as a standard. Taking for this the first point on the upward slope of the curve, viz., 37·5 degrees with ·14 ampere we may proceed to find the values of the currents for the other deflections, supposing the instrument for the time being to be a tangential one. Finding the current

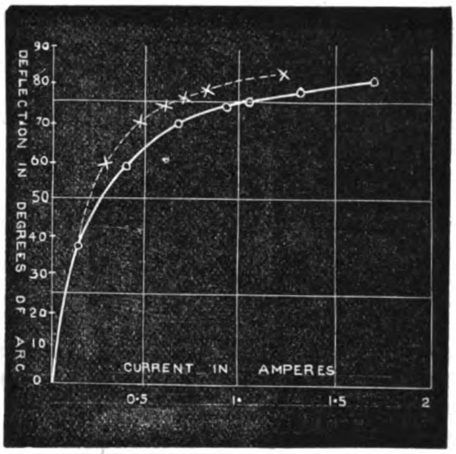

Fig. 59.

C for the next deflection of 58 degrees, we have, by simple proportion—

$$C : \cdot 14 :: \tan 58 : \tan 37 \cdot 5.$$

Hence,

$$C = \cdot 14 \times \frac{\tan 58}{\tan 37 \cdot 5},$$

$$= \cdot 14 \times \frac{1 \cdot 6}{\cdot 767} = \cdot 29 \text{ ampere.}$$

Now, 58 degrees was the deflection actually produced by ·39 ampere, but if the instrument had followed the tangent law the same deflection would have been produced by ·29 ampere. This is due to the large dimensions of the needle in comparison to the size of the coil. As the needle is deflected it moves into a weaker field owing to its length, and hence a stronger current is necessary to produce a given deflection than would be the case if the needle was of sufficiently short length to prevent its moving out of the uniform field during any part of its movement. Working out a few more points similarly to the above, keeping the first point, viz., that for the weakest current, as the standard, and plotting them on the same curve paper, the difference between the indicator in question and a true tangent instrument is made evident.

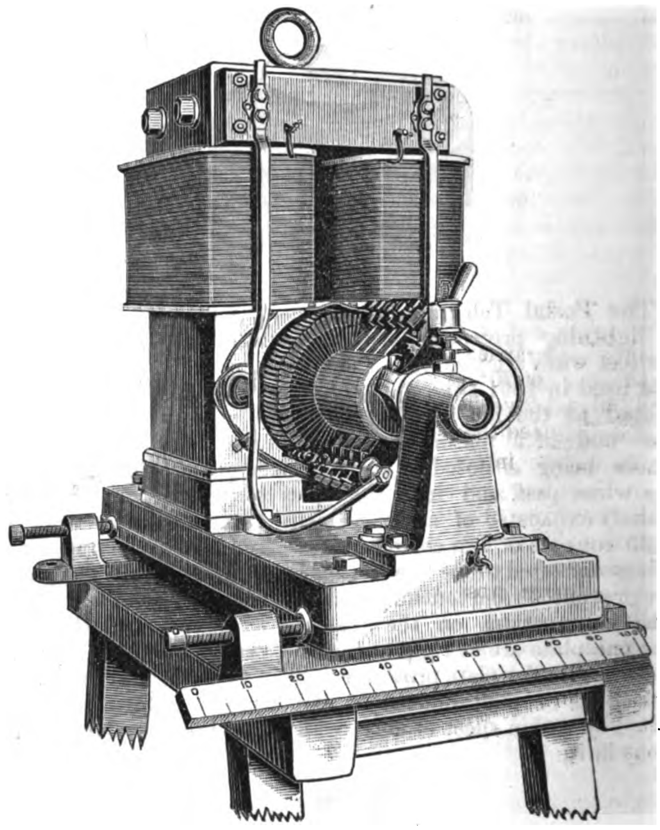
(To be continued.)

THE ARC LIGHT INSTALLATION OF THE INTERNATIONAL JUBILEE EXHIBITION OF FINE ARTS IN VIENNA.

(From a Vienna Correspondent.)

The Künstlerhaus, in which the International Jubilee Exhibition of Fine Arts is now being held, and which has been greatly enlarged and splendidly decorated for this purpose, is lighted throughout by 78 arc lamps of 10 amperes each.

Engines and Dynamos.—Two semi-fixed engines of 50 horse-power each have been hired for the time of the exhibition, and drive two large shunt-wound dynamos by means of countershafts. The one is a Marshall's compound engine working at a steam pressure of ten atmospheres, the other an engine constructed by



the Vienna States Railway Company, having two high-pressure cylinders and working at seven atmospheres. The dynamos are of the single horseshoe type with Gramme rings. The magnets are entirely made of the very best Styrian wrought iron, of a cross section of 465 by 200 millimetres; they rest with their poles on a zinc base. The armature core is built up of very thin soft iron sheets, kept together by insulated bolts, and insulated from one another by varnished paper. The windings are of rectangular sections, 12 millimetres by 5·7, every collector bar having one turn only. There are four pairs of brushes. The dynamos are capable of giving 70 volts and 430 amperes each at 500 revolutions per minute. Not the slightest spark is visible at the brushes. The electrical efficiency is 95 per cent.

Lamps.—The lamps are all in parallel, for the sake of absolute steadiness of the light, a result which has been fully attained. Each lamp is provided with an adjustable resistance in series with it. In these lamps a small single coil magnet wound with fine German silver wire, and having a resistance of 500 ohms, acts by an interrupting arrangement upon a ratchet wheel which is fixed upon a screwspindle; the latter is concealed within one of the carbon frame rods, and moves the upper carbon downwards. The feeding mechanism is exceedingly flat, the cap covering the whole not being higher than two inches. The lower

Digitized by Google

carbon is mounted on a soft iron armature, which is attracted by an electromagnet in the main circuit to strike the arc. The carbon rods used have a diameter of ⅝in. on the positive, ½in. on the negative side. The suspension of the lamps from the ceiling is effected by means of very flexible bare copper wire ropes passing over pulleys of relatively large diameter, the bearings of which are terminals at the same time. A disc-shaped counter weight is fastened to the other two ends of the ropes, which return from the ceiling, and slides up and down, guided on the ascending parts of the ropes by means of insulating porcelain bushes.

Every lamp is provided with a plug switch, mounted on the lamp casing, a small resistance frame carrying German silver spirals and a lead cutout. These frames are placed above the glass roofs, where all leads run. Pear-shaped opal globes are used.

Leads.—The whole system of distribution is divided into two circuits, each half of the building being fed from one circuit and one dynamo. All cables, wires, and safety catches are placed above the glass roofs from which the lamps are suspended.

The mains are made of bare copper rods, twenty-three millimetres in diameter, resting upon strong porcelain insulators. The connection between these house mains and the temporary engine shed forms an interesting detail of this installation. Four heavy bare copper cables are fixed to a strong framework projecting from the roof of the Künstlerhaus; they run down in an angle of 45 degrees to the roof of the engine shed, which is standing at the opposite side of the street on the slope of the Wien river. As the copper cables are very heavy they are suspended from four steel wire ropes running above the cables, and carried by insulators as well. The dynamos create an E.M.F. of 70 volts at the terminals, 3 volts are lost in the mains and 2 volts in the distributing leads, so that 65 volts remain to feed the remotest lamp.

It may be interesting to mention that nearly 300 telephone wires run immediately above the engine shed; the Telephone Company were protesting against the erection of the large dynamos in so close proximity to their lines, but there was no other place available. The mains carrying a current of over 800 amperes cross the telephone wires at right angles, and where the cables run parallel with them they are laid bifilar to avoid induction. It was feared that the leakage lines of the dynamos would produce a noise in the telephone wires; but it seems that they are all deflected into the boilers standing close by. The best proof of the absence of induction is this, that after the installation was already working for five days, a man came from the Telephone Company to inquire when we were going to start the station.

The whole installation was carried out by the firm of Messrs. B. Egger and Co., of Vienna, under the superintendence of their first engineer, Mr. Drexler, who designed also both dynamos and lamps.

THE AMERICAN BELL TELEPHONE SUIT.

We said when the decision in this great telephone suit was cabled from America a fortnight ago that it would be received here with general satisfaction, whatever were the grounds upon which the judgment had been given. This satisfaction will, we think, be more complete now that the full text is before us. Not only does it establish the Bell claims on what seems to us an unassailable legal footing, but it sets at rest once for all the sinister insinuations which had been imported into the case against the good faith of the man whose name will always be associated with one of the most wonderful discoveries of the present age. The Bell patents in Europe are not directly affected by the decision of the Supreme Court of the United States; but their position cannot fail to be strengthened by the evidence furnished in this case, with the result, it may be hoped, that the commercial progress of telephony will not be hampered by harassing and costly litigation. The assailants of the American Bell Telephone Company were numerous and powerful, no fewer than six companies being directly involved in the suit, those indirectly affected being, no doubt, still more numerous. It has been in progress for a considerable period of time, and sums of money have been spent on it proportionate to the magnitude of the interests at stake. Separately the cases have been tried at least once before, and some of them several times, always resulting in a triumph for the original company, except in one instance—that of the Molecular Telephone Company—and this exception has now been reversed on appeal, while in the other five cases the previous decisions have been upheld. The judgment of the Supreme Court is a complete victory for the Bell Company, and to all appearance a final one.

On the whole the chief points in dispute were not of a technical kind, but merely questions of fact, that is to say questions of priority, which were determined more by the credibility of the witnesses than by their scientific testimony. Excepting those put forward on behalf of REIS, the claims to anticipation, technically speaking, were insignificant and easily disposed of. Those preferred by Mr. DRAWBAUGH were of different character, and will be referred to later on. But as regards REIS' method, and indeed all the rest of the rival claimants, it is hard to see how BELL'S original claim, the fifth in his patent of March 7th, 1876, could be touched by them. It runs as follows:—

"The method of and apparatus for transmitting vocal or other sounds telegraphically, as herein described, by causing

electrical undulations similar in form to the vibrations of the air accompanying the said vocal or other sounds, substantially as set forth."

The invention as further described in the judgment "consists in the employment of a vibratory or undulatory current of electricity, in contradistinction to a merely intermittent or pulsatory current, and of a method of and apparatus for producing electrical undulations upon the line wire. A pulsatory current is described as one caused by sudden or instantaneous changes of intensity, and an electrical undulation as the result of gradual changes of intensity, exactly analogous to the changes in the density of air occasioned by simple pendulous vibrations."

Now, whatever the Reis telephone did or did not accomplish, it was certainly not by this method that he aimed at producing his results; and being the very essence of BELL'S discovery, its validity as a patent could not be upset by REIS' experiments with an entirely different method. REIS has not received full justice at the hands of the American Court, and we quite expect to see some of the *obiter dicta* of its judgment vehemently contested in this country, where the history and merits of the German inventor have been carefully studied. But as concerns this particular lawsuit, no one can seriously contest the general proposition that BELL succeeded where REIS had failed, because the former appreciated and the latter did not the true principles on which articulate telephony could be realised.

The one formidable claimant against Prof. GRAHAM BELL was Mr. DANIEL DRAWBAUGH, whose pretensions were represented in court by The People's Telephone Company. If the Drawbaugh telephone was what he and his associates represented it to be, it not only anticipated BELL'S apparatus in date but also in method. The two systems are indeed so much alike that unless by a miracle the one must have been a copy of the other. Mr. DRAWBAUGH dates his "conception and experiments" as far back as 1862, and the construction of various telephones, all on the same lines as GRAHAM BELL'S, in the years between 1866 and 1878—"perfectly adjusted and finished magneto instruments" being dated January and February, 1875; that is to say, a good twelve months prior to Bell's patent. DRAWBAUGH, however, never questioned the Bell patent till 1880 or 1881, although he went to see the Bell instruments exhibited at Philadelphia in May, 1876. Between that year and 1880 the Bell patent was being vigorously worked; hundreds of exchanges were in operation, and the telephone had evidently become a property of enormous value. Anybody, therefore, who had a telephone to patent straightway went and patented it; and there was no lack of financiers ready to take up anything that looked promising in that line of business. Mr. DRAWBAUGH'S telephones had been heard of, and he was interviewed. Some monetary transactions followed, by which one set of speculators acquired for a consideration all rights in the Drawbaugh telephones, and speedily parted with them for a much higher consideration to another and larger set of persons, who formed themselves into a company. It is no drawback to speculations of this kind that the invention about to be exploited will not work; it would not work even when brought into court in 1880; and the owners persistently refused to produce the terms of the specification alleged to have been drawn up the year previous. The great thing was to get plenty of witnesses to testify that they had heard and spoken through Mr. DRAWBAUGH'S telephonic instruments long before Mr. BELL'S were heard of. These witnesses were hunted up by the score, and their testimony has led three of the judges to dissent from the decision of the majority, on the ground that so many people could not all be mistaken. But there is no need to suppose them mistaken. Mr. DRAWBAUGH was an ingenious mechanic, and dabbled in electricity. He may, and probably did, experiment in electric telephony; but all that these people testify is to their speaking more or less inarticulately from his little shop to the cellar underneath, and to his telling them that it was done by electricity. He may have told them the truth; but for all they personally knew on this point the method he employed may have been as far removed from the Bell method as the string telephone is from the Hughes microphone.

Be this as it may, however, the failure to repeat these marvels of the shop and the cellar with appliances answering the same description in a court of law is, to our thinking, conclusive against any amount of evidence given by ignorant witnesses eight or ten years after the alleged occurrence. Coupled with the fact that DRAWBAUGH was familiar with the law of patents, being a patentee himself of at least two electrical inventions, and that he allowed BELL'S invention to go unchallenged for several years after it was fairly on the market, the above considerations entirely dispose of what little claim to originality there may have been in his "conception and experiments" between 1866 and 1876. It follows that if either of the parties copied the other's invention, the culprit was not Prof. GRAHAM BELL. In an equally conclusive manner have the graver charges against GRAHAM BELL and his solicitors been set aside relating to the alleged interpolation of his specification for the purpose of forestalling ELISHA GRAY. After a careful examination of the accusation sprung upon them at the last moment by the appellants, the judges declare that not a shadow of suspicion can rest upon any one in regard to this matter. The charge was a conjectural one at its worst, and rested solely on a discrepancy in relation to variable current in the specification, omitted in the copy furnished to BELL'S English agent. But as that document was no copy at all, and differed from the American specification in thirty other particulars, the single discrepancy fastened upon proves nothing, especially as it is an undisputed fact that BELL had this method of variable current under examination the year previous. Altogether, Mr. GRAHAM BELL comes well out of this unpleasant business, and we believe that every sincere admirer of the telephone will heartily congratulate him on the result.

ELECTRICAL STRESS.*

BY PROF. A. W. RÜCKER, M.A., F.R.S., AND MR. C. V. BOYS, A.R.S.M.

It is now some years since Dr. Kerr brought to the notice of the scientific world a most interesting method of demonstrating optically the stresses which exist in a dielectric between conductors of different potentials. His experiments have since been repeated and extended by Mr. Gordon, Quincke, Röntgen, and others. Mr. Gordon exhibited the phenomenon, using glass as the dielectric, in a lecture at the Royal Institution, and Prof. Silvanus Thompson tells us that he has shown it to his class with bisulphide of carbon. It is possible that others may have done the same; but in spite of these facts there is, I think, no doubt that the experiments are not as well known as their interest and importance demand.

Some weeks ago I had occasion to show one of them at a popular lecture, and since then Mr. Boys and I have been attempting to devise apparatus by which they might be readily exhibited to an audience. In the course of that time we have conversed on the subject with several well-known electricians, and found that many of them had not seen the simplest of the

* Paper read at the Society of Telegraph-Engineers and Electricians on Thursday, March 22nd.

Digitized by Google

phenomena which I hope presently to exhibit to you. I shall therefore offer no apology for bringing before the Society a subject the theoretical explanation of which is for the most part well understood.

There is, however, another point of view, namely, that of the teacher, from which I think lecture experiments on the optical demonstration of electrical stress are valuable. It is very desirable that students should from the first be impressed with the fact that the dielectric plays a part in electrical phenomena as important as that of conductors. In no way, perhaps, can this lesson be more clearly taught than by the glow, which, when the dielectric is investigated by polarised light, indicates the stresses to which it is subjected.

I will, however, begin my lecture by exhibiting an experiment of another kind, which illustrates the same fact. It is practically a reproduction of the method by which measurements of the specific inductive capacities of various substances were at first attempted.

Three insulated metal plates A, B, C are arranged parallel to each other. The two outer ones, B and C, are in connection with the opposite pairs of quadrants of a quadrant electrometer. They can be put to earth by connecting the insulated mercury cups in which the ends of the connecting wires dip with a third cup which is not insulated. The middle plate is then charged without any effect being produced on the electrometer. On breaking the earth connections and pushing a plate of paraffin attached to a long ebonite arm along a groove which directs it between the middle and one of the outer plates a deflection of the electrometer needle is obtained so large as to fling the index spot of light completely off the scale. The

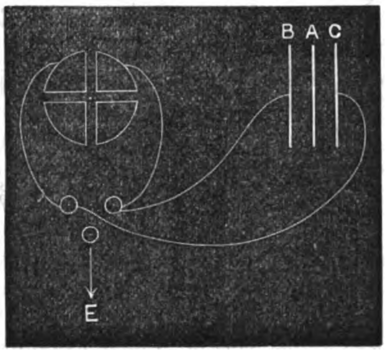

Fig. 1.

movement is in the same direction as that which would have been produced by reducing the distance between the two plates, and thus the experiment proves that induction takes place through paraffin more readily than through air. To meet the objection that the effect is due to the surface of the paraffin being moist or dusty, and that from these or from some other causes it has become a conductor, I touch it, and you observe that the deflection is unaltered. If, however, I repeat the experiment, enclosing the paraffin in a metal case, although the first effect is similar to that previously obtained, yet when I touch the metal the direction of the deflection is, as we should expect, suddenly reversed. [Experiment performed.]

Having thus illustrated the fact that the dielectric plays a part in the phenomena of induction, I may remind you of Maxwell's celebrated theory that it is, in such cases, in a state of stress. A tension exists along the lines of force, whilst a pressure is exerted in all directions at right angles to them. If this is so we should expect that a structure equivalent to that of a crystal in its effects on polarised light would be produced. The properties of the substance would be different in directions parallel and perpendicular to the lines of force. The tension and the pressure would affect them oppositely.

This fact Dr. Kerr utilised. Assume that the lines of force are horizontal, and that plane-polarised light, the vibrations of which take place in a direction inclined at 45° to the horizontal, enters the stressed dielectric. Let matters be further simplified by supposing that the ray of incident light is perpendicular to the lines of force. Under these circumstances the single ray may be regarded as broken up into two in which the vibrations will take place along and perpendicular to the lines of force respectively. These rays will travel with different speeds.

On emerging from the dielectric they may be regarded as recombining; but since one has travelled faster than the other, they do not in general recombine to produce plane-polarised light. If, then, before the electrical stress was produced, a Nicol's prism had been arranged to cut off the plane-polarised light, the production of the stress would modify the light so as to make it possible for a portion of it to pass through the prism.

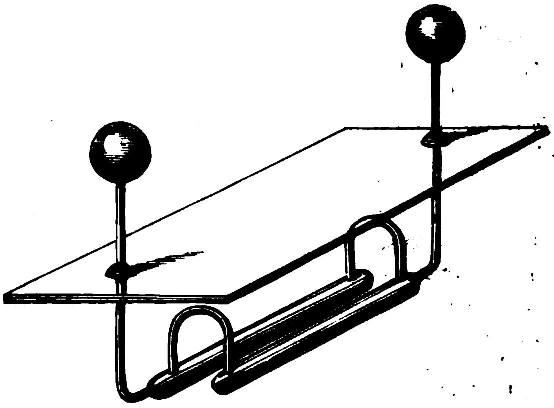

Fig. 1a.

A similar effect may readily be produced without the aid of electricity. I throw upon the screen the image of a small bar of glass. The light which falls upon it is plane polarised, and now a Nicol's prism is turned so as to cut it off. The field becomes dark. If, however, the glass be bent the concave side is compressed, the convex half is extended. The compression and extension take place in directions parallel to the length of the bar. Its dimensions perpendicular to its length are practically unaltered. Thus, its properties in directions parallel and perpendicular to its length are different. The incident light is broken up into two rays which travel with different velocities. These on recombining do not produce plane-polarised light. Some of the modified light can traverse the second Nicol's prism, and as the bar is bent you see it brightly illuminated on the screen. Regions of compression and extension are separated by a black line. In the parts which it traverses no alteration is produced by bending; the light emerges—as it entered—plane polarised, and fails to penetrate the second prism.

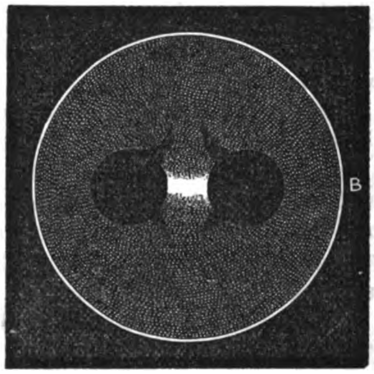

Fig. 1b.

I will now show you Dr. Kerr's fundamental experiment, which proves that there is a close similarity between the behaviour of the glass and that of a dielectric subjected to electrical stress. Dr. Kerr's observations were made by passing a beam of plane-polarised light between two metallic spheres immersed in carbon bisulphide. The light was extinguished by a Nicol's prism, but was restored when the spheres were oppositely electrified. It might, and probably would be possible with great care and by using a liquid quite

Digitized by Google

free from dust, to show the effect to an audience. It is, however, much better to use the apparatus shown in Fig. 1*a*. For spheres we employ two cylinders about 100 mm. in length. These are placed in a cell with glass ends, so that their axes are parallel and are perpendicular to the screen. Plane-polarised light is passed between them, and when an image is formed only the ends of the cylinders are seen, so that they present exactly the same appearance as two spheres would do. The light is extinguished by turning a Nicol's prism, but when an electrical machine, with which the cylinders are connected, is worked it is brightly restored (Fig. 1*b*). [Experiment.] For purposes of exhibition we obtain a great advantage by causing the light to traverse three or four inches of stressed liquid instead of a short distance in the neighbourhood of two spheres. To prevent the cylinders from being drawn together by the attraction which exists between them when they are oppositely electrified they are held apart by thin curved rods of glass, terminating in brass tubes which are soldered to the cylinders.

These experiments are attended with a certain risk, against which it is well to take precautions. The bisulphide is easily inflammable, and may catch fire if a spark passes in the neighbourhood of the cell. It is therefore necessary that the cells should not leak. They are made of wood with glass ends, and the joints are made tight with shellac varnish. The wires which support the conductors are passed through plates of glass, which cover the cell and thus prevent the free escape of the vapour. To make assurance doubly sure the cells are placed in a larger cell, so that if, as is sometimes the case, the glass ends are cracked by the passage of a spark through the liquid, the carbon bisulphide flows into the larger cell instead of falling on to the table or floor. This larger cell is itself placed in a wooden tray, the edges of which are turned up, and we have ready a tin plate extinguisher, which can be put over the whole apparatus in case the vapour should accidentally ignite.

The last experiment illustrates the fact that the dielectric between two oppositely electrified bodies is in a state of stress. An arrangement may easily be made to prove to a class that the tendency to separate observed in two similarly electrified bodies may be regarded as due to an attraction between each of them and surrounding bodies rather than to a direct mutual repulsion. Two cylinders arranged as before are placed between two vertical plates, which are parallel to the axes of the cylinders. Both cylinders and plates are immersed in bisulphide. The plates are connected with one terminal of the machine, the cylinders with the other. On electrification, two bright patches appear on the screen between each cylinder and the nearest plate. Taken in conjunction with the last experiment this illustrates the fact that there is an attraction between the cylinders and plates, and that the medium between the cylinders is not subjected to any considerable stress.

The next experiment introduces us to a point of some considerable theoretical interest. Glass touched by a hot poker becomes doubly refracting, because the temperature varies from point to point round the spot at which the heat is applied, but if it were uniformly warmed it would be singly refracting. There is, then, a difference between a crystal and a piece of unequally heated glass. In the former the molecules around any given point are differently arranged in different directions, but the constitution of the crystal is the same throughout. In the latter the temperature, and with it the arrangement of the molecules, varies from point to point. Now Prof. Quincke has shown that the volume of a dielectric alters when it is subjected to electrical stress, and the question arises whether the double refraction is produced, as it were, indirectly by this change of volume, or directly by what may be regarded as a crystalline arrangement of the molecules.

If the former view be correct, then as glass is doubly refracting only when it is unequally heated, a dielectric will exhibit the same property only when it is subjected to an electrical stress which varies from point to point. In the latter case double refraction will be produced by a uniform as well as by a variable stress.

Two parallel metal plates are now placed in the bisulphide; the light which passes between them is extinguished by the analysing Nicol. The plates are connected with the opposite terminals of the machine, and as soon as they are electrified the space between them is illuminated [Experiment.] (Fig. 2*b*.) If the bar of glass is held in front of the cell and bent, the black central line is broken. Where it crosses the stressed dielectric it is shifted towards the side on which the glass is compressed. Thus, when glass is compressed in a direction parallel to that in which the lines of force traverse the bisulphide, the double refraction produced on the liquid tends to neutralize that to which the compression gives rise in the glass (Fig. 2*c*).

Returning, however, to the question we were discussing, as to whether double refraction is produced in the bisulphide only where the stress is not uniform, it is remarkable that if plane-polarised light is passed through a plate of glass, the opposite sides of which are coated with oppositely electrified conductors, and which is placed between crossed Nicols, no re-illumination is produced by the electrification. This makes it important that the phenomenon should be more fully studied, and I will next show you an experiment which is conclusive as to the nature of the action in the liquid. The metal plates are replaced by two others similar to them in all respects, with the exception that in the upper parts of each of the plates

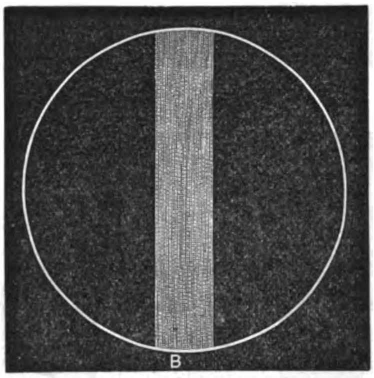

Fig 2b

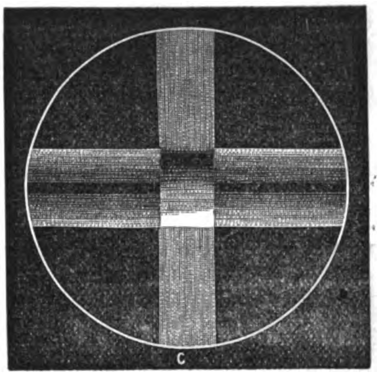

Fig. 2c.

two windows are cut which are exactly opposite to each other. The light, therefore, which traverses the space between the upper parts of the plates passes six edges, that which travels between the lower parts is brought near two edges only, but penetrates a far greater thickness of uniformly stressed liquid. If the double refraction is due to a quasi-crystalline constitution induced in regions of uniform stress, the light, when restored by electrification, will be bright in that part of the image which corresponds to the lower parts of the plates. If non-uniformity of stress is essential it will be brightest where it has passed near the greatest number of edges. [Experiment.] There is no doubt as to the result the uniformly stressed region is much the brighter. In glass, on the other hand, it appears that a stress which varies from one point to another is necessary to produce double refraction.

The next experiment is devised chiefly for use in an elementary lecture. The metal plates are bent twice at right angles, so that on the screen they represent the inner and outer coatings of a Leyden jar. To make the illusion a little more complete a

knob is attached to one of the wires (Fig. 3*a*). When the conductors are oppositely electrified a glow appears between them, which proves to the student that a stress is produced in the dielectric (Fig. 3*b*). At the two corners black brushes are seen, which are parallel to the principal planes of the two Nicols. [Experiment.] If before the plates are electrified the bar of glass be intro-

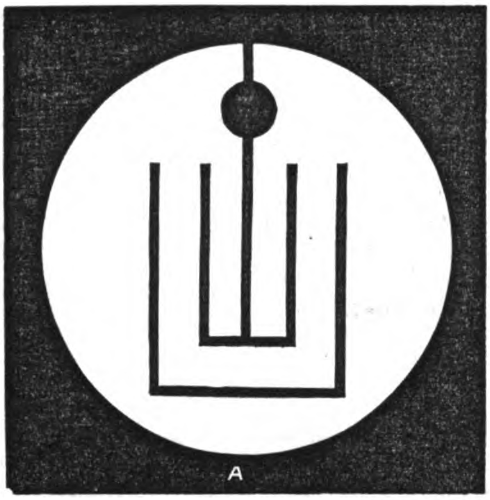

FIG. 3A.

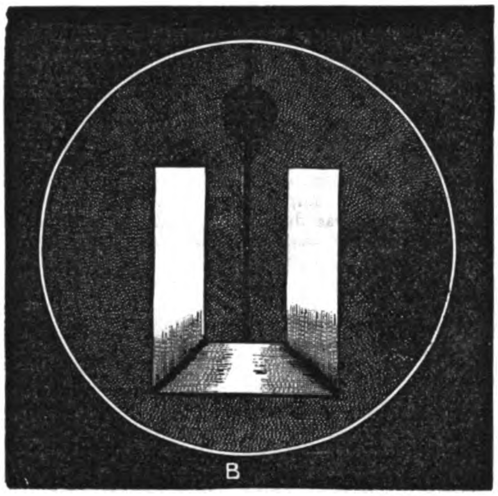

FIG. 3B.

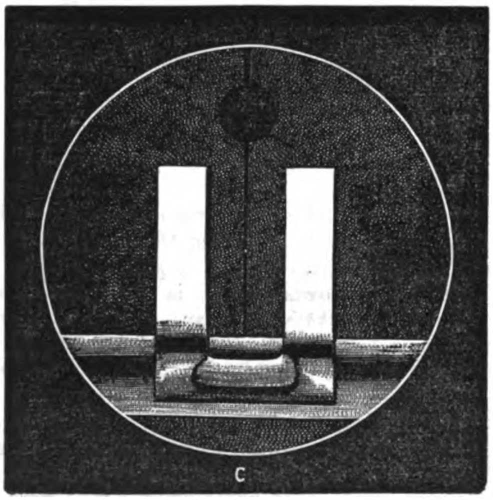

FIG. 3C.

duced and bent so that the black line which appears in its centre coincides with the bottom of the inner conductor, it will be observed that on electrification the line breaks into three parts. Between the vertical sides of the Leyden jar the lines of force are horizontal, and the bar is so bent that, as in a previous experiment, the black band is shifted upwards where it crosses them. Between the bottoms of the inner and outer coatings the lines of force are vertical, and the action will be reversed. The direction of relative compression and that of the vibrations which travel fastest in the stressed liquid, are both turned through a right angle, and here the black band travels downwards towards the outer coating. [Experiment.] (Fig. 3*c*.)

I will next use as conductors two cylinders placed one inside the other, with their axes coincident. On the screen they look like two concentric circles. When the light is extinguished and restored by electrification, the black cross so familiar in experiments on crystals is immediately visible. [Experiment.] (Fig. 4*b*.)

So far I have dealt only with cases in which the light which reappears on the screen is white; we will now modify the arrangements so as to produce colour effects.

When a very thin crystalline plate is interposed between crossed Nicols the light which traverses the second Nicol is white. You will remember that the restoration of the illumination depends upon the fact that the velocity with which the light travels varies with the direction of vibration. In the case of the dielectric vibrations are propagated at different rates, according as they are parallel or perpendicular to the lines of force.

This difference of speed is, however, itself different for lights of different colours, and if the thickness of the crystalline plate is increased, very beautiful colour phenomena are developed. The proportions of the different colours which traverse the second Nicol are widely varied. The emergent waves do not recombine to produce white light, and the tint actually observed changes with the thickness of the crystalline plate.

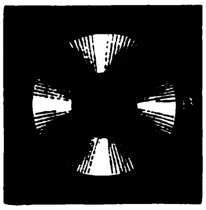

FIG. 4B.

The images of two wedge-shaped pieces of quartz are now thrown upon the screen, and you see that the colour varies from white at the thinnest ends, through orange, red, purple, and blue to green. [Experiment.] Curiously enough, the range of tints which these particular crystals exhibit is almost exactly the same as that which I hope presently to produce by electrification, though in the case of quartz the phenomenon is due to causes different from these I am now discussing.

In the case of a dielectric colours will be exhibited if we increase the stress sufficiently, even if the length of the liquid column traversed by the light is not largely augmented. I will therefore use a "Franklin's pane" in which the two plates are nearer together than in the previous experiment. The risk of discharge from the one plate to the other is now greater. The plates are therefore made thicker and the edges are carefully rounded. [Experiment.] As the machine is worked white light first appears. Now it begins to turn orange, which changes into red and purple. [On repeating the experiment the insulation was maintained until the green of the second order appeared on the screen.] The green of the second order is the tint which Dr. Kerr succeeded in reaching. Yesterday, when trying the experiment at South Kensington, we obtained the red of the second order, and have thus, I believe, carried the observations to a point on the scale of colours which had not been previously attained in this way. I will now repeat the experiment, placing a direct vision prism in front of the stressed liquid. When the plates are charged a spectrum appears on the screen. [Experiment.] A black interference band now enters from the violet. As the difference of potential increases it blots out the green and invades the red at the moment that a spark passes, and the phenomenon disappears.

The next experiment is a modification of the last. One of the two conductors is plane, the other is slightly curved. On

Digitized by Google

electrification the colours appear in the middle, where the conductors are nearest and the stress is the greatest. From this point they travel outwards in both directions, each tint, as the charge increases, being succeeded in regular order by those which follow it on Newton's scale. [In this experiment the colours varied from the green of the second order in the centre to the white of the first order near the edges of the conductors.]

I will now exhibit another modification of the experiments, by which no new point of theoretical interest is introduced, but which is very beautiful, and presents some practical advantages.

If a plate of selenite be introduced between the crossed Nicols the light is restored. The crystal we use is of such a thickness that the field is a rich blue. You can thus see the image of the apparatus before electrification. We will use first the two parallel metal plates. When they are electrified the retardation of one ray in the crystal will be augmented or decreased according to the direction of the lines of force, and the colour will change. [Experiment.] You now see that while the outer parts of the field remain blue, the central parts between the two metal plates alter to a purple red.

If we now use the concentric cylinders, the black cross appears as before, but the two pairs of quadrants become differently coloured. [Experiment.] The same phenomenon can be shown still more brightly in another way. Replacing the condenser by the Leyden jar apparatus, the blue changes in the vertical spaces to red, in the horizontal space to a greenish yellow. [Experiment.] The lines of force run in different directions, and the retardation, which is increased in the one case, is diminished in the other.

This concludes the experiments which I proposed to show you. As I have already remarked they have no novel theoretical interest; I venture, however, to believe that we have effected some improvements in the method of exhibiting them in public, and I hope that on that account a grave Society like that which I have the honour of addressing will forgive us for introducing to its notice phenomena which, if not new in principle, are at all events beautiful.

DISCUSSION.

After some complimentary remarks from Prof. FOSTER and Prof. ADAMS,

Mr. GORDON said that as these experiments illustrated the theories of Clerk Maxwell, it might not be out of place if he reminded the Society of a passage in a very little-known book of Clerk Maxwell, which was a little elementary text-book on electricity, published by the Christian Knowledge Society. In that book Clerk Maxwell had a speculation in which he pointed out that objects are seen by the sense of sight owing to its being able to detect differences in the amount of illumination of different bodies. We know that different bodies are of different potentials and different electrifications, and he speculated on what could be seen if we had a sense that would enable us to detect differences of electric potential as the eye does detect differences of optical potential—optical brightness. He thought Prof. Rücker's experiments had gone very far towards putting that sense at their disposal. It enabled them to see the differences of electrical potential, the possibility of seeing which in different bodies was predicted by Clerk Maxwell about fifteen years ago. It was very curious to see how every experiment seemed to confirm the ideas which the physical insight of Faraday, supplemented afterwards by the mathematical insight and theory of Clerk Maxwell, predicted. They all remembered Clerk Maxwell's beautiful conception that light itself was an electromagnetic disturbance. Clerk Maxwell, as they might remember, pointed out that the phenomena of electric induction might be explained by the supposition of an ether which should have certain properties and which would transmit the waves of electromagnetic induction. Maxwell then pointed out that by experiments on the ratio of electrostatic to electromagnetic units, and on specific inductive capacity, that the velocity of electromagnetic induction not only in air *in vacuo*, but in a great many other bodies could be determined, and he pointed out that if it should be shown hereafter that those velocities were the same, not only in air *in vacuo* but in other bodies, it would be a great confirmation of the theory that light itself is an electromagnetic disturbance. He remembered Clerk Maxwell saying to him, when he had the honour of being his pupil (he did not think it was in Clerk Maxwell's book), that it would be absurd to consider the whole of every part of space as filled with two ethers, which were exactly alike in their most important properties—exactly alike in every property that we could measure or discuss, and yet should be different and not the same. Maxwell's theory was, that the same ether transmitted the waves of electricity and the waves of light. Since then a great many experiments had been made. He had himself made a certain number of experiments on various substances, and Dr. Hopkinson had also made a great many. He thought they all found certain very curious resemblances and certain discrepancies. The electromagnetic and the electrostatic units were found to be practically identically equal to that of light; but whenever they came to gross substances, like paraffin and other solid substances, they had difficulties. Sometimes they found great resemblance, but sometimes great discrepancies. Directly they came to experiments on gas (he remembered that Prof. Ayrton and Prof. Perry published first experiments on gas) there was found, what might have been expected, that the disturbing forces acting in grosser substances were eliminated, and the velocities of light and electromagnetic induction were almost identically equal through the whole long series of gases. It seemed to him that evidence from gases, where there was not likely to be much internal friction or disturbing causes, was much more likely to be trustworthy than any evidence on the other side from solid bodies in which a number of extraneous conditions would appear. There was one other remark he would make. Prof. Rücker had very kindly alluded to some experiments he himself had made on the residual charge of a Leyden jar, which he showed at the Royal Institution. Although he had the honour of showing the experiments, they were made by Dr. Hopkinson, and communicated by that gentleman to himself, and shown by him at the Royal Institution soon afterwards.

Prof. PERRY thought that in the first experiment it was possible that the result was in reality due to a layer of moisture on the surface of the paraffin wax.

Prof. AYRTON believed that Faraday himself had tried for a very long while to show the stress in glass when it was electrified. He wished to ask Prof. Rücker whether, having made experiments in the subject, he had made any calculations as to the effect obtained compared with the mere electrostatic attraction due to the pressure of the two electrified coatings of the Leyden jar? Why was it they got so little effect with glass, which was supposed to be under electrical strain? He understood from Dr. Lodge that, as a matter of fact, the sort of effect they got with glass could really all be explained by the mere electrostatic attraction of the two electrified coatings squeezing the glass. With a very little pressure on a piece of glass they could produce quite as much effect, when tested by polarised light, as they could by producing very large differences of potentials in the two sides. If they had only experiments on glass, they would be inclined to think that the whole thing was mere pressure, and that there was not proved to be any electrical strain inside the glass at all. He did not mean to say for a moment that therefore one should conclude there was no electrical strain inside the glass, but merely that the experiment with polarised light did not prove its existence. When they came to the very beautiful effects that had been obtained that evening with carbon bi-sulphide, they could not apply the same explanation that the effect was due to mere electrostatic pressure. He would like to echo Dr. Hopkinson's question—Why it was that Faraday failed in glass? Why was it so extremely difficult when polarised light was seen through glass which was under electrical stress to get any effect under the polarised light? Dr. Lodge, he understood, regarded it as a kind of residual phenomenon. With regard to the action of the paraffin wax, he believed that the experiment of jacketing the slab of wax with metal was directed against himself personally, and therefore he would mention that he held his judgment in suspense. He was inclined to think that what he had seen that evening did not prove that they could with certainty measure the specific inductive capacity of paraffin wax in the way shown. He should be rather inclined to say that it proved that there were layers of moisture on the paraffin wax, because, as Prof. Perry remarked, they got about the same effect when they put a metallic coating on both sides of the paraffin wax as when they did not have paraffin wax at all. The conclusion to come to, therefore, was that there was some coating of moisture existing on the two sides of the paraffin wax. Why this coating of moisture was not entirely electrically discharged on touching it was perhaps because the paraffin wax was itself a good insulator and the film of moisture coating it was but an imperfect conductor, whereas the metallic coating could be discharged at once on touching it. The action of the moisture on the wax could, he thought, be represented by having the paraffin wax very clean and dry, and then dusting it *lightly* over with some fine metallic powder. Whether or not moisture played any important part in the experiment they had seen, he thought that too much care could not be exercised in eliminating the creeping effect that moisture produced in statical electrical experiments. The previous speakers had all spoken of the great pleasure they had derived from the lecture. The feeling was warmly shared by himself, for it was one thing merely to know or to teach, as they had been accustomed to do, that the electrical action of a Leyden jar took place in the dielectric and not in the coatings, and another thing to see this very action in the dielectric evidenced on the screen.

After a few words from Dr. JOHN HOPKINSON,

Prof. SILVANUS THOMPSON remarked that he thought they had reason to congratulate themselves on being Britons, as Continental text-books were still written under the shadow of the great Continental mathematicians, who, setting out from the law of inverse squares, had only realised action at a distance. From this, however, Faraday had delivered us, in proving the existence of stresses in the dielectric. Whilst Maxwell had speculated as to what we should see if endowed with an "electric sight," Faraday had in addition speculated as to what we should see with a magnetic sight, and in this connection had made his well-known experiments on the action of heavy glass, under the influence of a powerful magnetic field, on polarised light.

Prof. RUCKER, in reply, said that Prof. Ayrton's explanation of the experiment with the slab of paraffin involved a change in its properties during the experiment. If its surface was a conductor it must be a very

Digitized by Google

good conductor, as the movement of the electrometer was instantaneous and very considerable. It ought, therefore, when touched to behave like a good conductor; but the experiment proved, on the contrary, that if there was free electricity on the surface it could not be discharged by touching the paraffin. He had not repeated the experiments with glass, and it was much to be desired that the cause of the difference in the behaviour of glass and liquids should be more fully investigated.

Mr. BOYS said that if the electrostatic attraction referred to by Prof. Ayrton were really sufficient to produce in glass an effect as great as that due to electrical stress, then it was just possible that this might account for the absence of any luminous effect when glass was subject to a uniform electrical stress. In some materials the electrical stress along the lines of force was optically equivalent to a mechanical compression, and in some to a mechanical extension. If it should happen that in glass it should be equivalent to a mechanical extension, and should be equal optically to the compression caused by the electrostatic attraction, then since the two effects would be always equal whatever the difference of potential, one would neutralise the other, and the field would remain dark, as in practice is found to be the case.

UTILISATION OF ELECTRICITY IN SOUTH WALES MINING OPERATIONS.

ELECTRIC SHOT-FIRING, LIGHTING, AND SIGNALLING.*

The leading colliery owners of South Wales are discovering the advantages of the use of electricity in mining operations, and visits paid to some of the pits in the great coalfield of the Rhondda Valley have enabled me to witness the splendid results obtained in utilising the electric current for blasting, or "shot-firing," for lighting above and below ground, and for signalling.

I visited the Standard Colliery, Ynyshir, a few days ago, and, by the permission of the manager, was conducted over the entire works, above and below ground, and had the pleasure of practically testing the blasting apparatus by firing six shots myself.

First of all, let us glance at the electric appliances on the surface. There is a 100-volt dynamo, supplied by the Gülcher Electric Light and Power Company, with an arrangement for 100 lights of 16 candle-power, distributed over various parts of the colliery. The dynamo is 10 horse-power, worked by a Marshall steam engine of 6 horse-power, and it was explained to me that the management found it best to have the electric power of the machine larger than the mechanical power of the engine. In the colliery yard is a 5-arc lamp, while in the engine houses, stables, at the pit top, and in the most useful places below are incandescent lamps supposed to burn for 1,000 hours, but which have already been in use for thirteen months at the rate of 144 hours per week underground, and about half that time on the surface, and still they show no signs of wearing out. From the dynamo to the pit top, and thence down the shaft, the wires are fixed, and so arranged that the same lines of positive and negative are used for lighting, signalling and blasting; consequently, at a comparative trifling cost, the greatest efficiency is attained in all three departments of pit work. The value of the signalling apparatus may be imagined when it is stated that owing to its rapid action the management has been able to increase the output of coal by no less than fifty tons per day.

Accompanied by Mr. J. Thomas, overman, and others, I descended the shaft, which is 375 yards deep, and reaches the 2ft. 9in. seam. From this to the 4ft. seam, about 20 yards deeper, we proceeded along a drift, or dip, and as this is the vein worked at the colliery—from which there is an output of 700 tons a day—the main portion of the blasting was done here. It being Saturday, the miners had left working, and the officials primed the shot-holes, which had been bored in readiness. In the "East Dip" there were five holes, which were primed with clay. The wire was inserted, the connection with the dynamo having previously been taken off, and the shots were declared to be ready. Only a single wire was used, the "return" being made by the earth. We next went to the return side of the colliery, where two more shot holes were primed—and it may not be amiss here to remark that while the entire company carried safety lamps, my friend and I were favoured with portable electric lamps, one of Pitkin's and one of the Swan Company's. The latter gave a wider radius of light, while the former threw a stronger illumination directly in front—no doubt each having its relative merits. While we were inspecting the stables, engine planes, &c., which were brilliantly lighted, a messenger was sent to the surface to direct the man in the engine-house to stop the electric machinery, and when the current ceased, the switches were turned on, so that immediately the force of the current should be put on again the blasting would take place. The fixed lights at the pit bottom were extinguished, of course, by the stoppage of the engine, and the old system of signalling had to be resorted to when we wanted to ascend the shaft—viz., the ponderous hammer. However, the cage starts, and a little more than half a minute later we are at the pit top. The Marshall engine is once more started, and I place my hand upon a small lever, the moving of which sends the electric current along the wires to the shot-holes, about 900 yards away; and almost at the same instant the blasting takes place. There is not a soul in the pit. In this fact we see one of the advantages of blasting by electricity. It can be carried on from the surface to an unlimited extent, and if any of the shots happen not to go off you are, the moment the wires are disconnected, perfectly safe in going to examine the hole—a very different state of things from that of the old system of blasting.

We again descended to see the result, and, on getting to the bottom, switched off the electric current from the wires leading to the East Dip. The five holes in the East Dip were found to have been successfully fired, the hard stone top having been brought down as effectively as desired. In the "return" the two shots had failed, owing to either a bad cap or a faulty connection, and arrangements were made for properly blasting them. Such an arrangement hastens very materially the speed at which work can be carried on. The workmen like it because it is much safer than the old plan of firing by fuse, and the employers favour it because it is simple, economical, effective, and rapid, as well as, in the opinion of the management, calculated to reduce to a minimum the risk attendant upon blasting in mines.

Special interest attaches to the system—for we can no longer describe it as a mere experiment—when it is remembered that this was the colliery selected by the late Mr. T. E. Wales, Government Inspector of Mines, to become the subject of the "test case" directed to be taken by the Home Secretary, in order to set at rest a dispute between him and the South Wales Miners and mine owners as to the right of blasting without withdrawing the workmen. That, of course, was under the old Act, now superseded by the new Mines Regulation Act.

* From a Correspondent in the *Iron and Coal Trades Review*.

COMPARATIVE VALUE OF CONTINUOUS AND ALTERNATING CURRENT SYSTEMS FOR THE COMMERCIAL DISTRIBUTION OF ELECTRICITY.*

BY H. WARD LEONARD.

There exists to-day a great deal of uncertainty in the minds of many persons interested in the distribution of electric energy as to the comparative value of the continuous-current three-wire system and the alternating-current converter system; and as the published statements relative to these two systems have apparently greatly exaggerated certain advantages and disadvantages of the one system and the other, I will endeavour to institute what I consider as fair a comparison as possible between the two systems, using the best data at my command, and giving due weight to the several factors necessary in a general system for the distribution of electric energy on a commercial scale.

In considering the comparative value of these two systems, let us compare them with each other upon the following points, which I consider the vital ones in a general supply system of electric energy:—

First.—First cost.
Secondly.—Economy, efficiency and depreciation.
Thirdly.—Reliability.
Fourthly.—Variety and value of the possible sources of revenue.
Fifthly.—Safety to life.
Sixthly.—Effects upon existing property.

First: Cost and Economy.—This is a feature which is subject to variations which are not similar in the two systems, and it may be well to give some general explanations of the cause. In a three-wire system the principal items of cost are the generators, main conductors, and inside wiring. In the alternating system the main items of cost are generators, primary circuit, converters and secondary circuit.

The cost of the generators is, as far as I am able to judge by inspection and comparison of prices, about the same. At any rate, any possible difference in this respect must necessarily be but slight in its influence on the total cost of which it becomes a very small factor. We therefore come to a comparison between the cost of the feeders, mains and inside wiring of the three-wire, and the cost of the mains, converters, and inside wiring of the alternating system.

The cost of the conductors transmitting a given amount of energy at given loss for a given distance varies, generally speaking, inversely as the square of the initial electromotive force employed. For instance, if the E.M.F. of one system be 1,000 volts, and that of another be 110 volts, the cost of conductors for the latter under similar conditions would be to the cost of the former as 1,000,000 ($1,000^2$) : 12,100 (110^2), *i.e.*, as 82 : 1.

* Read before the Chicago Electric Club, March 5, 1888. The first of a series of Papers upon the subject, "The Continuous Current *v.* The Alternating Current," before the club.

Digitized by Google

In the three-wire system double the E.M.F. of the lamps is used, and the practical effect is the same as if the lamps were operated in series as far as the two outside conductors are concerned.

In order to secure complete independence of each individual lamp, a third wire, called the neutral wire, is run. This wire has a potential midway between those of the two outside wires, and in practice only carries the amount of current represented by the difference between the number of lamps burning on the two sides of the system.

Since the three-wire system has practically two lamps in series, and since the resistance of the two lamps in series is four times that of two lamps in multiple arc, it follows that, with the same number of lamps, the resistance of the lamp circuit is in the three-wire system four times that of the two-wire system. Therefore, for the same percentage of loss due to the resistance of the conductors, the size of the wires for the three-wire system need be only 25 per cent. the size and cost of those for a two-wire system. The neutral wire, if it be of the same size as the outside wires, would add one-half more to the cost, making the total cost, instead of 25 per cent., 37½ per cent. of the two-wire system. In practice the size of the neutral wire is less than that of the outside wires in the feeders, and the cost is thereby reduced so that in practice the cost of conductors is 33 per cent., or one-third of the cost of the wo-wire system.

We saw that the cost of a conductor for a 110-volt two-wire system and a 1,000-volt converter system was as 82 is to 1. It is now evident that by using the three-wire system this ratio becomes as 27·5 is to 1.

The three-wire system is not, of course, limited to the electromotive force quoted. The Edison Company operate dynamos of 1,200 volts in a three-wire system for their municipal system. The standard three-wire system of to-day is limited by the difficulty in manufacturing lamps of much higher voltage than 110. When the time comes, and it seems near at hand, that lamps can be had of double the voltage of those, the cost of conductors of the three-wire system will be one-fourth of what it is to-day ; or, in other words, existing conductors will be able to supply four times as many lamps as at present, and at the same loss ; also, an increase in the economy of the incandescent lamps would reduce the cost of conductors proportionately, and we can, of course, expect to see very great improvement in this direction.

It is evident, therefore, that the cost of conductors in the three-wire system will be reduced by inevitable improvements in the lamp itself to but a small fraction of its present cost.

Now let us look at the alternating system under similar conditions. Outside of the generator the converter is the principal item of cost, the cost of conductors being slight in comparison, as we will see later. An increase in the voltage of the lamps would be of no benefit whatever, and an increase in the economy of the lamps would result in a proportional reduction in the cost per lamp. Let us suppose that the voltage of existing lamps be doubled, and the economy increased 25 per cent., both of which results are likely to be seen in a very few years, if not sooner. The cost of conductors for the three-wire system would be reduced 80 per cent. and the cost of converters would be reduced 20 per cent., or, in other words, existing three-wire conductors would be able to supply five times as many lamps as at present, an increase in capacity of 400 per cent., and existing converters would be able to supply 25 per cent. more than at present.

So much for the probable reduction in first cost consequent upon improvements in the economy of the lamp itself, the only place in any incandescent system where much increase in economy can be expected, as existing devices are all claimed to, and most of them do, show an individual efficiency of 90 per cent. and upwards.

Let us now examine the comparative cost as these systems exist to-day. In order to do this it becomes necessary to determine the cost of conductors under the varying conditions met with in practice ; and this can be conveniently done by applying the following formula deduced by the writer, the accuracy of which has been tested by practical use for about two years :—

Let T C P be the total candle-power.

Let D be the mean distance current travels (one way).

Let L equal price per pound of copper (in cents).

Let V be volts lost in conductors (both ways).

Let E be E.M.F. of lamps.

Let C H P be candles per electrical horse-power.

Then
$$\$ = \frac{T\,C\,P \times D^2 \times L}{V \times E \times C\,H\,P \times 1{,}000}.$$

For the three-wire system one-third of this.

Before proceeding to apply the formula let us clearly understand that with a continuous current the loss in conductors is exactly proportional to the amount of energy they transmit ; *i.e.*, any variation in the load causes a proportional variation in the loss in conductors.

With the alternating current this is not the case, the decrease in the energy transmitted resulting in but a slight decrease in the current. Thus, with a continuous current the loss in conductors under conditions of one-quarter load is one-quarter what it is at full load, but with the alternating current the loss in conductors at one-quarter load is probably 75 per cent. of what it is at full load. However, as this conclusion is based mainly on theoretical grounds, I will, in comparison, grant that the alternating current will be as efficient in this respect as the continuous current.

Careful examinations of the load diagrams of some 50 Edison central stations show that throughout the run the average load is from 33 to 40 per cent. of the maximum load ; *i.e.*, if the loss in conductors is 10 per cent. when the full load is on, the average loss throughout the whole time the plant is supplying light is but 4 per cent.

Table I shows the maximum loss expressed in volts, the corresponding maximum per cent. of loss, the corresponding average per cent. of loss, and consequently the average efficiency of the system of conductors.

TABLE I.

System.	Three-wire System.			1,000-Volt Alternating-Current System.		
Maximum loss in volts	12·5	20	30	25	50	100
Maximum loss in per cent......	10	15	20	2·5	5	10
Average loss in per cent.	4	6	8	1	2	4
Average efficiency	96	94	92	99	98	96

These two tables show the individual efficiency of the different portions of the two systems, and the total efficiency from the driving belt up to and including the portions named. I have granted in all cases for the converter system an efficiency of 98 per cent. for the primary, and 99 per cent. for the secondary conductors. With a commercial efficiency of 90 per cent. for the generator, and 95 per cent. for the converter, which is sometimes claimed for them by some, the total efficiency is 82·9 per cent. With a commercial efficiency of 85 per cent. for the generator, and 90 per cent. for the converter, which is believed by others to be liberal, the total efficiency is 74·2 per cent. In the three-wire system we have assumed an efficiency of the generator of 92 per cent., which result is obtained by every maker of a first-class dynamo of this type, and an efficiency of 99 per cent. for both the mains and the inside wiring, both of which portions of the system are in practice calculated for a maximum loss of 2 per cent.

The maximum loss in the feeders in Table No. 2 is made 10, 15 and 20 per cent., with a corresponding average loss of 4, 6 and 8 per cent., and an efficiency of 96, 94 and 92 per cent.

TABLE II.

Alternating-Current Converter System.

	Indv.	Total.	Indv.	Total.	Indv.	Total.
Efficiency of generator.........	90	90	88	88	85	85
Efficiency of feeder	98	88·2	98	87·2	98	83·3
Efficiency of converter.........	95	83·8	92	79·3	90	75
Efficiency of services and inside wiring	99	82·9	99	79·5	99	74·2

Three-Wire System.

	Indv.	Total.	Indv.	Total.	Indv.	Total.
Efficiency of generator.........	92	92	92	92	92	92
Efficiency of feeder	96	88·2	94	86·5	92	84·6
Efficiency of mains	99	87·3	99	85·6	99	83·7
Efficiency of services and inside wiring	99	86	99	84·7	99	82·9

Assuming the highest efficiency claimed for the alternating-current generator, and assuming the generator is as efficient as a continuous-current generator under conditions of partial load—which is not likely—and assuming that the converter has the same efficiency under partial load as under full load—which we know cannot be—we still are met with the fact that the three-wire system with a maximum loss of 20 per cent. in the feeders has as high an efficiency as the converter system, allowing it every possible claim, and that the three-wire system as usually installed, with a maximum of 10 per cent. loss in feeders, has a superior efficiency of from 4 to 12 per cent. over the alternating-current converter system.

To return now to the question of first cost, assuming the cost of copper at 16 cents per pound, I have figured the cost of copper con-

Digitized by Google

ductors for feeders for 16 candle-power; 50-watt lamps for distances of 1,000, 2,000, 3,000, 4,000, 5,000, and 6,000ft., with an average loss in conductors of 4, 6, and 8 per cent. for the three-wire system, and 2 per cent. for the alternating system with 1,000 volts initial E.M.F.; cost is expressed in dollars and decimal fractions thereof.

TABLE III.

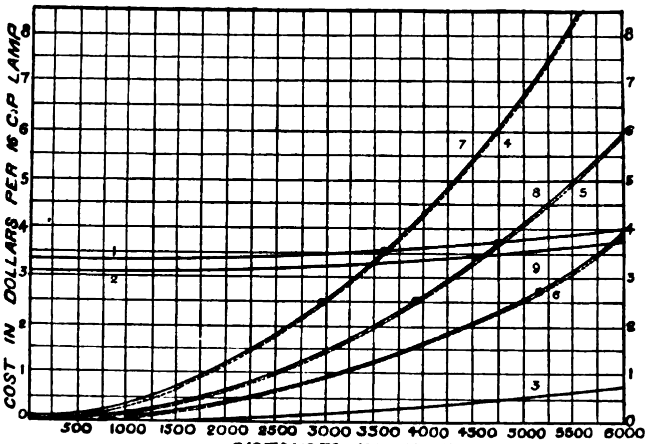
Cost of Copper for Three-Wire Feeder, per 16 candle-power lamp (50 watts 110 volts). Copper at 16 cents per lb.

Distances	1,000	2,000	3,000	4,000	5,000	6,000
12·5 volts maximum loss equals 5 volts average loss, which is 4 per cent.	·266	1·064	2 394	4·256	6·65	9·576
20 volts maximum loss equals 8 volts average, which is 6 per cent.	·1615	·646	1·453	2·584	4 037	5·812
30 volts maximum loss equals 12 volts average, which is 8 per cent.	·1077	·430	·969	1·723	2 69	3·87

Cost of Primary and Secondary Circuits and Converters for 1,000 Volt Alternating-Current Converter System, per 16 candle-power lamp, at varying distances.

Distances	1,000	2,000	3,000	4,000	5,000	6,000
Primary	·0213	·085	·191	·340	·530	·764
Converter	3 000	3·000	3·000	3·000	3·000	3·000
Secondary	·240	·240	·240	·240	·240	·240
Total	3·2613	3·325	3·431	3·580	3·770	4·004

I have also calculated the cost of copper in the mains for one 16 candle-power lamp on the basis of a distance of 800ft. between feeder terminals in the three-wire system and a maximum loss of 2 per cent., and find it to be thirteen cents. Also the cost of services and inside wiring in the three-wire system on basis of an average distance to lamps of 100ft., and 2 per cent. loss, and since the full benefit of the three-wire distribution cannot be attained in the inside wiring, have assumed the saving of one-third over the two-wire system instead of the two-thirds saving effected in cases where the full benefit can be attained. On this basis the cost of copper for services and inside wiring is six and one-half cents per lamp.



In the alternating-current converter system I have assumed the cost of converters recently quoted by Mr. Stanley, the electrician of the Westinghouse Company, in a Paper before the Boston Society of Arts. This figure is three dollars per lamp. I have calculated the cost of copper per 16 candle-power 50-volt and 50-watt lamp with an average distance to the lamp of but 75ft., and with 2 per cent. loss, and found the cost of copper to be 24 cents per lamp. With an average distance of 100ft., as was assumed in the case of the three-wire system, the cost of conductors for the inside wiring would be 43 cents. In making the comparisons, however, we will give them the advantage due to the 75ft. distribution; that is, 24 cents per lamp.

I have plotted these results expressing cost as ordinates, and distances as abscissæ. The curves resulting are shown here. [See diagram.]

In the diagram, curve number 1 shows cost of primary converter and secondary for alternating system (converters at $3 per lamp).

Number 2 shows cost of primary and converter for alternating system.

Number 3 shows cost of primary for alternating system.

Number 4 shows cost of feeders for average loss of 4 per cent.

Number 5 shows cost of feeders for average loss of 6 per cent.

Number 6 shows cost of feeders for average loss of 8 per cent.

Number 7 shows cost of feeders and mains for average loss of 9 per cent.

Number 8 shows cost of feeders and mains in the three-wire system for average loss of 6 per cent.

Number 9 shows cost of feeders and mains in the three-wire system for average loss of 8 per cent.

In the three-wire system curves for total cost are the lines in black just above the dotted lines.

It will be seen that if the three-wire system be operated at an average efficiency of 92 per cent. in the feeder, which corresponds to the highest efficiency claimed for the alternating-current converter system, the total cost per lamp would be equal when the average length of feeder was 6,000ft. An average length of feeder of 6,000ft. corresponds to circular area 18,000ft. in diameter; that is, about 3½ miles in diameter. In practice, it is preferable to operate at higher efficiency, making a large investment in copper, which has the strong recommendation of having the least depreciation, and requiring the least attention of anything used in connection with the transmission of energy.

The middle curves represent an average efficiency of 94 per cent. in the feeder; that is, an average loss of 6 per cent. in the feeder. You will notice that even with this superior efficiency the three-wire system is cheaper per lamp than the alternating-current converter system at an average length of feeder of 4,750ft., corresponding to a circular area of 12,000ft. in diameter, and that for shorter distances the cost rapidly diminishes—the cost of conductors for three-wire system at this efficiency with an average length of feeder of 3,000ft. corresponding to circular area of 9,000ft. in diameter being less than one-half the cost of conductors and converters for the alternating system.

Even with the very high efficiency of 96 per cent. in the feeder, or an average loss of but 4 per cent., the conductors of the three-wire system are cheaper than the conductors and converters of the alternating-current converter system for an average length of feeder of 3,600ft. or less, and this corresponds to a circular area of 11,000ft. in diameter.

Suppose that both the generator and converter are so much cheaper than we have assumed as above that it makes a total reduction of one dollar per lamp. We then find that under conditions of equal efficiency, 82·9 per cent., the three-wire is cheaper where the average distance to lamps is one mile or less. With the usual efficiency for the three-wire system, 84·7 per cent., it is the cheaper for an average distance to lamps of 4,000ft. or less, and with the highest efficiency, that is, 86·5 per cent., with average loss of 4 per cent. in the feeders, the three-wire system would be the cheaper when the average distance to lamps is 3,000ft. or less.

Suppose, on the other hand, that the incandescent lamp be doubled in voltage, and increased 25 per cent. in economy; at the same time that the cost of converter was reduced to two-thirds its present cost, and we find that with the highest efficiency, 96 per cent. in the feeders, the three-wire system would be the cheaper for cases where average distance to lamps is 8,000ft. or less, which corresponds to a circular district about five miles across.

Before leaving the question of economy of operation, let us look at the question of depreciation. In any dynamo the depreciation naturally becomes greater when it is operated at high E.M.F., even where the type is the same, and in the high E.M.F. alternating-current generator there exists the greatest tendency toward troubles due to the breaking down of the insulation of the wire on the armature. The secondary circuit of the alternating-current system and the inside wiring of the three-wire system would have a similar depreciation, but there is a great difference between the depreciation of copper conductors carrying low E.M.F. continuous currents and the depreciation of highly insulated conductors carrying a high E.M.F. alternating current together with the depreciation on an expensive piece of apparatus like the converter, the large proportion of the cost of which is represented by labour. Try to compare the value of copper twenty years hence which costs $1,000 to-day with $1,000 of converters, and small highly insulated wire such as is used in the primary circuit of the alternating system, and I think it will be evident that the depreciation of the alternating system is going to be many times that of the three-wire system.

Reliability.—In ordinary practice in the three-wire system every lamp is partially supplied by every feeder on that side of the system. That is, the current can flow out on any such feeder and through the network of mains, and finally reach the individual lamp. Similarly, every lamp is supplied in part by every dynamo operating in multiple arc on that side of the system, so that the larger the system, the more reliable it becomes, and an accident to

Digitized by Google

an individual main, feeder, dynamo belt or engine does not in any way affect the operation of the light, and in the worst event trouble in an individual building would only result in half the lamps on that circuit going out, and the other half would be scattered alternately among those which would go out, so that the result would not be even troublesome.

Now how about the alternating system? Thus far they have not found it practicable to operate their generators in multiple arc, and it is not likely that they will ever be able to in common practice. This means more than is generally appreciated. Every lamp burning on an alternating system depends upon the continuous operation in unison of six separate appliances, each of which is liable at any moment to cause an instantaneous extinction of the light in question. These six things are :—

First. The individual secondary circuit which supplies the lamp.
Second. The individual converter which supplies the lamp.
Third. The individual primary circuit which supplies the lamp.
Fourth. The individual generator which supplies the lamp.
Fifth. The individual belt for the generator.
Sixth. The individual engine which supplies the power.

The next best thing to reliability is ability to reduce the time the light is out to a minimum, and to accomplish this it becomes necessary to install a spare system of conductors which are only brought into service when a primary circuit gets into trouble. An expensive switch-board in the central station also becomes necessary, so that in case of trouble to a generator its load can be thrown over to another generator with the least possible effect upon the lights that the generator has been supplying. The secondary circuits from one primary can be multiple arced, and this is sometimes done, and this adds somewhat to the reliability of the light, but the expense due to this connecting of converters by heavy wires required by 50-volt lamps makes it impracticable in usual instances.

Unless the alternating-current generators are operated in multiple arc, the reliability of the alternating system cannot be as good as that of an arc light system, and we all know how reliable that is.

Variety and Value of the Possible Sources of Revenue.—We now come to the consideration of the variety and value of the possible sources of revenue. The first and most important revenue for a central lighting station outside of the light itself is power.

In a central station running night and day, the cost of generating additional power beyond that required for the light is quite small—probably not exceeding $30 per horse-power per year for ten hours per day. This amount of power distributed in small units as required in practice will readily sell for $100 per year. Owing to the fact that a large number of small motors, varying in their requirements as to power from moment to moment, are supplied from one common source, a certain production of horse-power will supply the demands of motors representing a total maximum horse-power some 2½ times as much as is produced. In other words, for every horse-power produced at $30 you can sell 2½ at $100 each, or you can sell for $250 what it has cost you $30 to produce. It goes without saying that the ability to supply such demands is of the utmost importance to a central station. The continuous-current system is well adapted to the supply of power for any and all purposes. No practical method of operating a motor by means of the alternating current has as yet been devised, and the problem presents great difficulties, principally on account of the necessity of a comparatively continuous current for charging the fields, and the instability of the torque of such a motor.

We are promised great results and extended use of the storage battery, and undoubtedly it will be used considerably for a great many purposes, therefore there is a large possible revenue from this source, which the alternating system will not be able to supply.

Then there is almost unlimited number of applications of a continuous current on a small scale for such purposes as fire alarms, burglar alarms, distribution of time, annunciators, tickers, electroplating, telegraph lines and telephones, all of which rely on a continuous current; and there are innumerable applications which will soon develop consequent upon the absolute reliability and constancy of the electrical pressure at command. Out of the numberless applications of the electric current which we see daily, I can think of no commercial application except the production of light and heat, for which the alternating current under discussion is available, and the production of heat by the electric current does not present a flattering outlook as a source of revenue to the owners of central station plants. Therefore we see that to-day the alternating system is dependent for its revenue upon the sale of light alone, while the continuous current is applicable to almost every conceivable use to which the electric current is put.

Safety to Life.—The safety to life of the three-wire continuous-current system using about 230 volts as a maximum E.M.F. is undoubtedly absolute. It is impossible for a consumer of such a system to injure himself by the shock in any conceivable way, and a slight burn in case he makes a short circuit in too close proximity to some portion of his person is the worst result possible, and this is almost an unheard-of possibility. It has been conclusively proven in practice that the 1,000-volt alternating current is fatal to human life, and will kill a horse. Although perhaps not likely to occur, it is always possible for the primary and secondary to get into contact either in the converter itself, or possibly in circuits outside of it. Any person handling the wires of the secondary and a fairly good ground is then liable through a possible ground elsewhere to be instantaneously killed. The most dangerous thing is the one which is usually perfectly safe, and occasionally dangerous, as is witnessed by the death of a telephone operator at Pittsburg recently. While he was, as usual, handling various contacts about the switch-board, a high electromotive force circuit became closed somewhere outside with the telephone line, and without the slightest suspicion of any possible danger he was instantly killed in doing what he had done thousands of times before.

Effects Upon Existing Property.—The low E.M.F. of the ordinary three-wire system, the perfect protection from excessive current effected by the safety devices in use and the continuous character of its current render it practically inert as far as its influence upon existing property is concerned. That the alternating system, with its high E.M.F. and its strong inductive influence, will occasionally cause serious trouble to existing telegraph, telephone and other lines, which it is adjacent to, seems inevitable.

From the foregoing comparisons, I consider the alternating current is not applicable to central station lighting, as it is at present operated, except as a possible occasional adjunct, or else upon an extremely small scale in cases where a few lights very greatly scattered are required, and where power is cheap. In cases where cheap power exists at a distance of several miles from a town capable of supporting a station of 2,000 lamps and upwards, high initial E.M.F. becomes both desirable and necessary, but the continuous-current converter, which already exists in several forms, and which is receiving the attention of the best electricians and inventors of the world, will, in my opinion, be the device to supply this demand, and that very shortly.

JUDGMENT OF THE SUPREME COURT OF THE UNITED STATES IN THE TELEPHONE APPEALS.

Mr. Justice BLATCHFORD: This opinion is in case No. 113, *Amos E. Dolbear* and other appellants, versus *The American Bell Telephone Company*, an appeal from the Circuit Court of the United States for the District of Massachusetts.

In cases No. 361 and 362, which are cross-appeals from the Circuit Court of the United States for the Southern District of New York, one by the *Molecular Telephone Company* and others, appellants, against *The American Bell Telephone Company* and another, and a cross appeal by *The American Bell Telephone Company* and another, versus *The Molecular Telephone Company* and others.

Another case is No. 709, *The Clay Commercial Telephone Company* and others, appellants, versus *The American Bell Telephone Company* and others, an appeal from the Circuit Court of the United States for the Eastern District of Pennsylvania.

Another is case No. 770, *The People's Telephone Company* and others, appellants, against *The American Bell Telephone Company* and others, an appeal from the Circuit Court of the United States for the Southern District of New York.

Another is case No. 771, *The Overland Telephone Company* and others, appellants, against *The American Bell Telephone Company* and others, an appeal from the Circuit Court of the United States for the Southern District of New York.

The opinion is written by the Chief Justice.

BELL'S CLAIM FOR THE ART.

The important question which meets us at the outset in each of these cases is as to the scope of the fifth claim of Bell's patent of March 7th, 1876, which is as follows :—

"The method of and apparatus for transmitting vocal or other sounds telegraphically, as herein described, by causing electrical undulations similar in form to the vibrations of the air accompanying the said vocal or other sounds, substantially as set forth."

It is contended that this embraces the art of transferring to or impressing upon a current of electricity the vibrations of air produced by the human voice in articulate speech, in such a way that the speech will be carried to and received by a listener at a distance on the line of the current. Articulate speech is not mentioned by name in the patent. The invention, as described, consists in the employment of a vibratory or undulatory current of electricity, in contradistinction to a merely intermittent or pulsatory current, and of a method of and apparatus for producing electrical undulations upon the line wire.

A pulsatory current is described as one caused by sudden or instantaneous changes of intensity, and an electrical undulation as the result of gradual changes of intensity, exactly analogous to the changes in the density of air occasioned by simple pendulous vibrations.

Among the uses to which this art may be put, is said to be the tele-

Digitized by Google

graphic transmission of noises or sounds of any kind; and it is also said that the undulatory current, when created in the way pointed out, will produce through the receiver at the receiving end of the line, a similar sound to that uttered into the transmitter at the transmitting end. One of the means of imparting the necessary vibrations to the transmitter to produce the undulations may be the human voice. Articulate speech is certainly included in this description, for it is an uttered sound produced by the human voice.

It is contended, however, that "vocal sounds" and "articulate speech" are not convertible terms, either in acoustics or in telegraphy. It is unnecessary to determine whether this is so or not. Articulate speech necessarily implies a sound produced by the human voice. As the patent, on its face, is for the art of changing the intensity of a continuous current of electricity by the undulations of the air caused by the sonorous vibrations, and speech can only be communicated by such vibrations, the transmission of speech in this way must be included in the art. The question is not whether vocal sounds and articulate speech are used synonymously as scientific terms, but whether articulate speech is one of the vocal or other sounds referred to in this claim of the patent. We have no hesitation in saying that it is, and that if the patent can be sustained to the full extent of what is now contended for, it gives to Bell, and those who claim under him, the exclusive use of this art for that purpose until the expiration of the statutory term of his patented rights.

In this art, or what is the same thing under the patent law, this *process*, this *way* of transmitting speech, electricity, one of the forces of nature, is employed; but electricity left to itself will not do what is wanted. The art consists in so controlling the force as to make it accomplish the purpose.

It had long been believed that if the vibrations of air caused by the voice in speaking could be reproduced at a distance by means of electricity, the speech itself would be reproduced and understood. How to do it was the question. Bell discovered that it could be done by gradually changing the intensity of a continuous electrical current, so as to make it correspond exactly to the changes in the density of the air caused by the voice. This was his art. He then devised a way in which these changes of intensity could be made and speech actually transmitted. Thus his art was put in a condition for practical use. In doing this, both discovery and invention, in the popular sense of those terms, were involved; discovery in finding the art, and invention in devising means of making it useful; and for such discovery and such invention the law has given the discoverer and inventor the right to a patent; as discoverer for the useful art, process and method of doing the thing he has found, and as inventor for the means he has devised to make the discovery one of actual value. Other inventors may compete with him for the ways of giving effect to the discovery, but the new art he has found will belong to him and those claiming under him during the life of his patent. If another discovers a different art or method of doing the same thing, reduces it to practical use, and gets a patent for his discovery, the new discovery will be the property of the new discoverer, and thereafter the two will be permitted to operate, each in his own way, without interference by the other. The only question between them will be whether the second discovery is in fact different from the first.

A patent for the art does not necessarily involve a patent for the particular means employed for using it. Indeed, the mention of any means in the specification or descriptive portion of the patent is only necessary to show that the art can be used; for it is only useful arts, arts which may be used to advantage, that can be made the subject of a patent. The language of the Statute is:—

"Any person who has invented or discovered any new or useful art, machine, manufacture or composition of matter may obtain a patent."

That is section 4886 of the Revised Statutes. It is an art, a process which is useful, and is as much the subject of a patent as a machine, manufacture or composition of matter. Of this there can be no doubt. It is abundantly supported by the authorities. *Corning* v. *Burden*, 15 How., 252-271. *Tilghman* v. *Proctor*, 12 How., 707-735. *Fermentation Company* v. *Maus*, 20 Fed. Rep., 725.

What Bell claims is the art of creating changes of intensity in a continuous current of electricity exactly corresponding to the changes of density in the air caused by the vibrations which accompany vocal or other sounds, and of the use of the electric condition that is thus created for sending and receiving articulate speech telegraphically. For that, among other things, the patent of 1876 was, in our opinion, issued, and the point to be decided is whether as such a patent it can be sustained.

In *O'Reilly* v. *Morse* (15 How.) it was decided that a claim in broad terms for the use of the motive power of the electric or galvanic current for making intelligible characters, letters or sounds at any distance, although a new application of the power was made by Morse, was void, because it was a claim for a patent for an effect produced by the use of electro-magnetism, distinguished from the process or machinery necessary to produce it.

But a claim for making use of the motive power of magnetism when developed by the action of said current, substantially as set forth in the foregoing description, as a means of operating or governing the motion or machinery that is to impart signals in any desired manner for the purpose of producing telegraphic communication at any distance, was sustained. The effect of the decision was, therefore, that the use of magnetism as a motive power, without regard to the particular process with which it was connected in the patent, could not be claimed, but that its use in such a connection could.

In the present case the claim is not for the use of a current of electricity in its natural state, as it comes from the battery; but for putting a continuous current in a closed circuit into a certain specific condition suited to the transmission of vocal and other sounds, and using it in that condition for that purpose. So far as at present known, without this peculiar change in its condition it will not serve as a medium for the transmission of speech, but with the change it will. Bell was the first to discover this fact and how to put such a current into such a condition. What he claims is its use in that condition for that purpose, just as Morse claimed his current in his condition for his purpose. But we see nothing in the Morse case to defeat Bell's claim. On the contrary, it is in all respects sustained by that authority. It may be that electricity cannot be used at all for the transmission of speech except in the way Bell has discovered it, and that therefore practically his patent gives him its exclusive use for this purpose. But that does not make his claim one for the use of electricity as distinguished from the particular process with which it is connected in his patent. It will, if it is true, show more clearly the great importance of his discovery, but it will not invalidate his patent.

SUFFICIENCY OF THE SPECIFICATION.

But it is insisted that his claim cannot be sustained, because, when the patent was issued Bell had not in fact completed his discovery. While it is conceded that he was acting on the right principle, and had adopted the true theory, it is claimed that his discovery lacked that practical development which was necessary to make it patentable. In the language of counsel "there was still work to be done, work calling for the exercise of the utmost ingenuity, and calling for the very highest degree of practical invention."

It is quite true that when Bell applied for his patent he had never actually transmitted telegraphically spoken words so that they could be distinctly heard and understood by the listener at the receiving end of his line; but in his specification he did describe accurately and with admirable clearness his process—that is to say, the exact electrical condition that must be created to accomplish the purpose. He also described with sufficient precision to enable one skilled in such matters to make it, a form of apparatus, which, if used in the way pointed out, would produce the required effect, receive the words and carry them to and deliver them at the appointed place. The particular instrument which he had, and which he used in his experiments, did not, under the circumstances in which it was tried, reproduce the words spoken so that they could be clearly understood; but the proof is abundant and of the most convincing character that other instruments carefully constructed and made in exact accordance with the specifications without any additions whatever have operated and will operate successfully. A good mechanic of proper skill in matters of the kind can take the patent, and by following the specification strictly, can construct an apparatus which, when used in the way pointed out, will do all that it is claimed the method or process will do.

Some witnesses have testified that they were unable to do it, but this shows that they, with the particular apparatus they had and the skill they employed in its use, were not successful; not that others with another apparatus perhaps more carefully constructed or more skilfully contrived would necessarily fail. As was said in *Loom Company* v. *Higgins*, when the question is whether a thing can be done or not it is always easy to find persons to show how not to do it. If one succeeds, that is enough, no matter how many others fail. Opposite results will show that in the one case the apparatus used was properly made, and carefully adjusted with a knowledge of what was required, and skilfully used; and that in the other it was not. The law does not require that a discoverer or inventor, in order to get a patent for a process, must have succeeded in bringing the art to the highest degree of perfection. It is enough if he describes the method with sufficient clearness and precision to enable those skilled in the matter to understand exactly what the process is, and if he points out some practical way of putting it in operation. This Bell did.

He described clearly and distinctly his process of transmitting speech telegraphically by creating changes in the intensity of a continuous current or flow of electricity in a closed circuit, exactly analogous to changes of density in the air occasioned by the undulatory motion given to it by the human voice in speaking. He then pointed out two ways in which this might be done, one by the vibration or motion of bodies capable of inductive action, or by the vibration of the conducting wire itself in the neighbourhood of such bodies; and the other by alternately increasing and diminishing the resistance of the circuit, or by alternately increasing and diminishing the power of the battery. He then states that he prefers to employ for his purpose an electro-magnet having a coil on one of its legs, and he describes the construction of the particular apparatus, shown in the patent as figure 7, in which the electro-magnet or magneto method was employed. This was the apparatus which he himself used without entirely satisfactory results, but which Prof. Cross, Mr. Watson, Dr. Blake, Mr. Pope and others, testify has done and will do what was claimed for it—transmit speech successfully, but not as well indeed as another constructed upon the principle of the microphone or variable resistance method.

THE PATENT NOT LIMITED TO SPECIFIC APPARATUS.

An effort was made in the argument to confine the patent to the magneto instrument and such modes of creating electrical undulations as could be produced by this form of apparatus, the position being that such an apparatus necessarily employed a closed circuit incapable of being opened, and a continuous current incapable of being intermittent. But this argument ignores the fact that the claim is, first, for the process, and, second, for the apparatus. It is to be read, as *first*, a claim for the method of transmitting vocal or other sounds telegraphically, as herein described, by causing electrical undulations similar in form to the vibrations of air accompanying the vocal or other sounds substantially as set forth, and, *second*, for an apparatus for transmitting vocal or other sounds telegraphically as herein described, by causing electrical undulations substantially as set forth.

Digitized by Google

The *method*, "as herein described," is to cause gradual changes in the intensity of the electrical current used as the medium of transmission, which shall be exactly analogous to the changes in the density of the air occasioned by the peculiarities in the shapes of the undulations produced in speech, in the manner substantially as set forth; that is to say, by the vibration or motion of bodies capable of inductive action, or by the vibration of the conducting wire itself in the neighbourhood of such bodies, which is the magneto method: or by alternately increasing and diminishing the resistance of the circuit, or by alternately increasing and diminishing the power of the battery, which is the variable resistance method. This is the process which has been patented, and it may be operated in either of the ways specified. The circuit must be kept closed to be used successfully; but this does not necessarily imply that it must be so constructed or so operated upon as to be incapable of being opened. If opened, it will fail to act for the time being, and the process will be interrupted; but there is nothing in the patent which requires it to be operated by instruments which are incapable of make and break. The *apparatus*, "as herein described," which is included in the claim, is undoubtedly one in which the electro-magnet is employed, constructed substantially as set forth in the specification. The one acting on the variable resistance mode is not described further than to say that the vibration of the conducting wire in mercury or other liquid included in the circuit occasions undulations in the current; and no very specific directions are given as to the manner in which it must be constructed. The patent is both for the magneto and variable resistance *methods* and particularly for the magneto *apparatus* which is described or its equivalent. There is no patent for any variable resistance *apparatus*.

It is undoubtedly true that when Bell got his patent he thought the magneto method was the best; indeed, he said in express terms he preferred it. But that does not exclude the use of the other, if it turns out to be the most desirable way of using the process under any circumstances. Both forms of apparatus operate on a closed circuit by a gradual change of intensity, and not by alternately making and breaking the circuit or by sudden and instantaneous changes, and they each require to be so adjusted as to prevent interruptions. If they break, it is a fault, and the process stops until the connection is restored.

It is again said that the claim, if given its broad construction, is virtually a claim for speech transmission by transmitting it, or in other words, for such doing of the thing as is provable by doing it. It is true Bell transmits speech by transmitting it, and that long before he did so it was conceived by scientists that it could be done by means of electricity. if the requisite electrical effect could be produced. Precisely how that subtle force operates under Bell's treatment, or what form it takes, no one can tell. All we know is, that he found that by changing the intensity of a continuous current so as to make it correspond exactly to the changes in density of the air caused by sonorous vibrations, vocal and other sounds could be transmitted and heard at a distance. This is the thing to be done. Bell discovered the way of doing it. He uses electricity as the medium for that purpose, just as air is used within speaking distance. In effect, he prolongs the air vibrations by the use of electricity. No one before him had found out how to use electricity with the same effect. To use it with success it must be put in a certain condition. What that condition was he was the first to discover, and with his discovery he astonished the scientific world. Prof. Henry, one of the most eminent scientists of the present century, spoke of it as the greatest marvel hitherto achieved by the telegraph. The thing done by Bell was the transmitting of audible speech through long telegraph lines. Sir William Thomson on returning to his home in England in August or September, 1876, after seeing at the Centennial Exhibition in Philadelphia what Bell had done and could do by his process, spoke in this way of it to his countrymen:—

"Who can but admire the hardihood of invention which devised such a slight means to realise the mathematical conception, that if electricity is to convey all the delicacies of quality which distinguish articulate speech, the strength of the current must vary continuously as nearly as may be in simple proportion to the velocity of the particle of air engaged in constituting the sound."

Surely a patent for such a discovery is not to be confined to the mere means he improvised to prove the reality of his conception.

BELL'S METHOD NOT IN REIS' APPARATUS.

We come now to consider the alleged anticipation of Philipp Reis; and here it is always to be kept in mind that the question is not whether the *apparatus* devised by Reis to give effect to his theory can be made with our present knowledge to transmit speech, but whether Reis had in his time found out a way of using it successfully for that purpose; not as to the character of the apparatus, but as to the mode of treating the current of electricity on which the apparatus is to act, so as to make that current a medium for receiving vibrations of air created by the human voice in articulate speech at one place, and in effect delivering them at the ear of the listener in another place. Bell's patent is not alone for the particular apparatus that he describes, but for the process that apparatus was designed to put into use. His patent would be just as good if he had actually used the Reis apparatus in developing the process for which it was granted. That Reis knew what had to be accomplished in order to transmit speech by electricity is very apparent, for in his first paper he said:—

"Since it is possible to produce anywhere or in any manner vibrations whose curves shall be the same as those of any given tone or combination of tones, we shall receive the same impression as that tone or combination of tones would have produced on us."

Bourseul also knew before Reis that this was the case, for in a communication published in the Paris journals in 1854 he said:—

"When you reproduce precisely these vibrations, to wit, the vibrations made by the human voice in uttering syllables, you will reproduce precisely those syllables."

Reis discovered how to reproduce musical tones, but he did no more. He could sing through his telephone, but he could not talk. From the beginning to the end he has conceded this. In his first paper he said:—

"Hitherto it has not been possible to produce the tones of human speech with a distinctness sufficient for every one. The consonants are for the most part reproduced pretty distinctly, but the vowels as yet not in an equal degree. The cause of this I will attempt to explain."

And again:—

"I have succeeded in constructing an apparatus with which I am enabled to reproduce the tones of various instruments, and even to a certain extent the human voice."

None of the many writers whose papers are found in the records claim more than this for Reis or his discovery. Although his first paper was published in 1861, Bell did not appear as a worker in the field of scientific research until nearly fifteen years afterwards. No advance had been made by the use of what Reis had contrived, nor by the use of his method, towards the great end to be accomplished. He caused his instrument to be put in the market for sale, and both he and those he employed for that purpose took occasion to call attention to the instruments by their prospectus, catalogues, and otherwise, describing what they were and what they would do. In his own prospectus, which was published in 1863 and attached to the apparatus, he said:—

"Every apparatus consists of two parts, the telephone proper and the receiver. These two parts are placed at such distance from each other that the singing or toning of a musical instrument can be heard in no other way from one station to the other except through the apparatus.

"Both parts are connected with each other and with the battery B, like common telegraphs. . . The galvanic current goes . . . . through the copper strip to the platinum leaf on the middle of the membrane, then through the foot of the angle to the screw *b*, in whose hollow a small drop of mercury is placed. . .

"If now sufficiently strong tones are produced in front of the sound-opening S, through the vibrations of the same, the membrane and the angular-shaped little hammer lying upon it are set in vibration; *the circuit is alternately opened and closed at every full vibration* and hereby are produced in the iron rod of the spiral at station C the same number of vibrations, and those are perceived there as tone or tone combinations.

"Besides the human voice there can be produced (according to my experience) just as well the tone of good organ pipes from F—c and those of the piano."

Albert, the mechanician employed to make the instruments, in his catalogue published in 1866, enumerates among the things he has for sale "the telephone of Reis for reproducing tones by electricity;" and in a work on electricity by Ferguson, published in London and Edinburgh, in 1867, it is said in speaking of the telephone:—

"This is an instrument for telegraphing notes of the same pitch. Any noise producing a single vibration of the air, when repeated regularly a certain number of times a second, not less than 32, produces, as is well known, a musical sound. A person when singing any note causes the air to vibrate so many times per second, the number varying with the pitch of the note he sings. The higher the note the greater the number of vibrations. If we then by any means can get these notes to break a closed circuit, a note sung at one station can be reproduced, at least so far as pitch is concerned, at another. The Reis telephone, invented in 1861, accomplishes this in the following way."

It is needless to quote further from the evidence on this branch of the case. It is not contended that Reis ever succeeded in practically transmitting speech, but only that his instrument was capable of it if he had known how. He did not know how. All his experiments in that direction were failures. With the help of Bell's later discoveries in 1875, we now know why he failed.

As early as 1854 Bourseul, in his communication which has already been referred to, had said substantially that if the vibrations of air produced by the human voice in articulate speech could be reproduced by means of electricity at a distance the speech itself would be reproduced and heard there. As a means of stimulating inquiry to that end he called attention to the principle on which the electric telegraph was based, and suggested the application of that principle for such a purpose. He said:—

"The electric telegraph is based on the following principle:—An electric current passing through a metallic wire circulates through a coil around a piece of soft iron, which it converts into a magnet. The moment the current stops this piece of iron ceases to be a magnet. This magnet takes the name of electro-magnet.

"This magnet, the electro-magnet, can thus alternately attract or let go a movable plate, which by its movements back and forth produces the conventional signals used in telegraphy."

Then, after referring to the mode in which speech is transmitted by the vibrations of the air, he said:—

"Suppose a man speaks near a movable disc sufficiently flexible to lose none of the vibrations of the voice, and that this disc alternately makes and breaks the connection with the battery; and you may have at a distance another disc which may simultaneously execute the same vibrations."

That Reis was working all this time, from the beginning to the end of his experiments, upon the principle of the telegraph as thus suggested by Bourseul is abundantly proved. In his first paper, after describing his cubical block apparatus, he said:—

Digitized by Google

"If, now, tones, or a combination of tones, are produced in the neighbourhood of the blocks, so that sufficiently powerful waves enter the opening *a*, then these sounds cause the membrane *b* to vibrate. At the first condensation the hammer-like wire *d* is pushed back; at the rarefaction it cannot follow the retreating membrane, *and the current traversing the strip remains broken*, until the membrane forced by a new condensation presses the strip (proceeding from *p*) against *d*. In this way *each sound causes a breaking and closing of the current.*"

Such was the beginning, and it was maintained persistently to the end, as well by Reis as by those who availed themselves of what he was doing. To this the Reis-Legat apparatus forms no exception, for in the paper describing it Legat says:—

"The operation of the apparatus described is as follows:

"When at rest the galvanic circuit is closed, when the air, which is in the tube *a b* of the apparatus, Fig. 4 A, is alternately condensed and rarefied by speaking into it (or by singing or introducing the tones of an instrument), a movement of a membrane closing the smaller opening of the tube is produced, corresponding to such condensation or rarefaction. The lever, *c d*, follows the movements of the membrane, and opens and closes the galvanic circuit at *d g*, so that at each condensation of the air in the tube the circuit is opened, and at each rarefaction the circuit is closed.

"In consequence of this operation, the electro-magnet of the apparatus, Fig. 4 B, in accordance with the condensations and rarefactions of the column of air in the tube *a b*, Fig. 4 B, is correspondingly demagnatised and magnetised, and the armature of the magnet is set into vibrations like those of the membrane in the transmitting apparatus."

We have not had our attention called to a single item of evidence which tends in any way to show that Reis, or anyone who wrote about him, had in his mind anything else than that the intermittent current caused by the opening and closing of the circuit could be used to do what was wanted. No one seems to have thought that there could be any other way. All recognised the fact that the minor differences in the original vibrations had not been satisfactorily reproduced, but they attributed it to the imperfect mechanism of the apparatus used, rather than to any fault in the principle on which the operation was made to depend.

It was left for Bell to discover that the failure was due not to workmanship, but to the principle which was adopted as the basis of what was to be done. He found that what he called the intermittent current, one caused by alternately opening and closing the circuit, could not be made, under any circumstances, to reproduce the delicate forms of the air vibrations caused by the human voice in articulate speech; but that the true way was to operate on an unbroken current, by increasing and diminishing its intensity. This he called a vibratory or undulatory current, not because the current was supposed to actually take that form, but because that language expressed with sufficient accuracy his idea of a current which was subjected to gradual changes of intensity, exactly analogous to the changes of density in the air occasioned by its vibrations. Such was his discovery, and it was new. Reis never thought of it, and he failed to transmit speech telegraphically. Bell did, and he succeeded. Under such circumstances it is impossible to hold that what Reis did was an anticipation of the discoveries of Bell. To follow Reis is to fail, but to follow Bell is to succeed. The difference between the two is just the difference between failure and success. If Reis had kept on he might have found out the way to succeed; but he stopped and failed. Bell took up the work, and carried it on to a successful issue.

OTHER ALLEGED ANTICIPATIONS OF BELL'S METHOD.

As to what is shown to have been written and done by Dr. Van der Weyde, it is only necessary to say that he copied Reis, and it was not until after Bell's success that he found out how to use a Reis instrument so as to make it transmit speech. Bell taught him what to do to accomplish that purpose.

As to James W. M'Donough, we presume it will not be claimed that he is entitled to more than he asked for in his application for a patent, filed in the Patent Office, April 10th, 1876. There, a circuit-breaker so adjusted as to break the connection by the vibration of the membrane is made one of the elements of his invention. The Patent Office was clearly right in holding him to have been anticipated by Reis.

The patents of Cromwell Fleetwood Varley, of London, England, one dated June 2nd, 1868, and the other October 8th, 1870, were for improvements in the electric telegraph. The objects of the invention covered by the first are to cut off the disturbance arising from earth currents, and to obtain a high speed of signalling in long circuits; and the object of the second was the increase of the transmitting power by enabling more than one operator on a single wire to send more than one message to independent stations. In the specification it is said—

"By my invention I superpose upon the currents used for working the ordinary telegraphs rapid undulations or waves which do not practically alter the mechanical or chemical power of the ordinary signal currents, and by new apparatus, hereinafter described, these undulations are made to produce distinct and independent audible or other signals so long as these undulations are produced, whether ordinary signal currents be flowing or not."

In short, there is nothing in any part of the specification to indicate that the patentee had in his mind undulations resulting from gradual changes of intensity exactly analogous to the changes in the density of air occasioned by simple pendulous vibrations, which was Bell's discovery, and on which his art rests. His purpose was to superpose, that is to say to place upon the ordinary current another, which by the action of the make-and-break principle of the telegraph, would do the work he wanted.

(To be continued.)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 24th*, 1888.

You have no doubt already been advised by cable of the rendering of the decision of the United States Supreme Court in the matter of the Bell patents. After litigation which extended back for several years, and after a prolonged period of suspense, those interested in the patents find themselves reassured and happy, and those who fought in the opposition are correspondingly disappointed and depressed. The legal fight has been one for length and costliness almost without precedent, and the issues at stake have been of the first magnitude. While the Court was not unanimous in its decision, and though the majority was far smaller than could be desired in establishing the validity of great fundamental patents, the triumph is none the less a fact. By the morning of Monday last little doubt was left that the decision would be rendered that day, and the telephone quotations in the Stock Market in Boston on the previous Saturday were higher and stronger than they had been some months past, the shares of the American Bell Telephone Company being quoted at 240, or just $100 per share more than at the time immediately preceding the decision against Drawbaugh by Judge Wallace. As soon as the Chief Justice began reading the decision in court it became tolerably clear that the verdict would be for Bell, and long before the end was reached it was seen that Bell's claims had been approved and reasserted in a manner which would make them hereafter practically unassailable. There were six cases up for review, being the suits won by the Bell Company against the Dolbear, Drawbaugh, Clay, Molecular, and Overland Companies, and the case in which the Molecular Company had obtained a decree against the Bell Company. The finding of the Court was that the various Reis apparatus were useful only and solely for transmitting musical tones, and that nothing that Reis had ever invented could affect the validity of the Bell patents. The trouble with Reis was, not merely bad workmanship in his instruments, but an utter failure to arrive at the only principle, as Bell did, upon which speech could actually be transmitted. Reviewing briefly the Dolbear, Van der Weyde, M'Donough, Varley and other claims as not really material, the Court then proceeded to pay its respects to the appeal of the People's Company, basing on the claims of Daniel Drawbaugh, the mechanic of Aberly's Mills, the little village in Pennsylvania, where we have been told the talking telephone was invented by Drawbaugh, as early as 1869. The Court admitted the profuseness of the evidence brought to support Drawbaugh's assertions, but discredited his story on the ground that his conduct had never been consistent with the idea that he had reached a complete discovery or invention which could be put to any practical use. The Court held that to suppose Drawbaugh had discovered the art of telephony before Bell did would be to construe testimony without regard to the laws that govern human conduct. It was on this point that the Court divided, a minority of three out of seven holding that this obscure mechanic of Pennsylvania did discover the practical telephonic art, and was entitled to the merit of being the first inventor. On no other point did the Court divide; the important claims of Dolbear, strange to say, being dismissed lightly, while the extravagant claims made by Drawbaugh had a weight which nobody had anticipated for them. The decision also included a discussion of the charges of collusion and fraud made against Bell and his attorneys, and the Court held that nothing had been brought to light that smirched in the slightest degree the professional integrity or moral character of those whose honour had been thus assailed.

Naturally this important decision is the engrossing topic at the present time. It cannot be said that the decision was at all unexpected, nor can it be said that it contains anything in the slightest degree new or original; in fact, we should have to go back to the Dowd, Spencer and Eaton cases for the first reference to Reis's alleged anticipations, and from 1881 down to the present time the story of

Digitized by Google

the various inventors and anticipators has been told over and over again in the technical press and the daily journals until even mere allusion to the matter has become wearisome. The general opinion in professional circles appears to be that while for the extended use of the telephone it might have been well to open up opportunities for competition, the effect on patents generally is a wholesome one, by showing that patents can safely be made the basis of large new industrial developments. On the other hand, it is thought by some that this confirmation of what is regarded by a great many as a monstrous monopoly will lead to serious attempts to tamper with the patent system. As we have those attempts, anyhow, this decision cannot make the situation materially worse.

It hardly seems likely that we shall now see any serious attempts to start up the matter again by litigation, and with security promised them the various telephone companies may be expected to exert themselves in the direction of extending their business and solidifying their position. The probability is that the long-distance business will be pushed with greater rapidity than ever. It is surprising how great already is the network of long-distance wires. Thus, for example, we have Boston, New York, Philadelphia, and Washington all in a line able to communicate from one to the other, and it is an interesting fact worthy of note that on Monday when the decision was rendered bulletins as to the decision were received from minute to minute here in New York at telephone head-quarters over the long distance lines from Washington. Last week, in the middle of the great storm, when the telegraph wires broke right and left for hundreds of miles and were absolutely useless, the telephone lines came to our aid, and were found of the utmost service. Just what the Western Union is going to do about it we do not know yet, and there is room in this respect for speculation and conjecture.

I have just alluded to the storm; we are still recovering from it, and hardly yet, in the rush of extra work that it involves, have had time to define our sensations and realise what it really was. The damage done to the aërial wires proves to have been far heavier than even was at first supposed. In some places the destruction was complete. The telegraph lines between New York and Washington, for instance, will have to be almost entirely rebuilt, there being, so report goes, no fewer than 1,000 poles down between these two cities. The fact is that, although magnificent efforts have been made all around New York and Boston to put the lines in good shape, the repairs are in a great many cases only of a temporary character, sufficient to renew the service but not equal to the strain of continuous work. The Western Union Company has just declared its quarterly dividend of 1½ per cent., but the estimates do not include the blizzard, and as the loss will certainly be very large, the dividend may not be so substantial next quarter.

I believe you have already been advised of the intention of the Thomson-Houston Company to go into the electric railway business here. The electrical journals this week report that negotiations have now been concluded, and that the Van Depoele Company has transferred to the Thomson-Houston Company all its rights and patents in this department. It is generally understood that the Thomson-Houston Company will push the work in this field with its wonted dash and energy. It is fortunate in securing the assistance of Mr. C. J. Van Depoele, who is to devote himself to the development of the electric railroad system. Mr. Van Depoele, who is of Belgian extraction, is a very bright electrician, and a man whose indomitable pluck is only equalled by his unquenchable good humour. He has done much to give this country its prestige in electric railway matters, and amid all the troubles, disasters, and discouragements of the earlier days, has pegged away with a cheery doggedness that has been of incalculable value to this newest electrical application. I think that with the opportunities now presenting themselves, he will be able to make many marked improvements on his old work, and with the necessary capital to lead the way to a development for which no parallel can be found, even in our electric lighting annals.

Electrical Boston is very much stirred up just now by the efforts being made there to secure for certain parties the exclusive privilege to construct, establish, and maintain conduits for undergrounds of all descriptions. The applicants for the privilege say that if the city will put down the conduits, and then let them to different parties, they are perfectly willing to have the matter left in that shape; but if the city will not do it, then, in view of the emergency of the case, private capital should be invited by concessions; and it was a question, to which there could be but one answer, whether the authority should be given to one company to construct conduits which would carry all the wires, or whether a number of companies should be authorised each to put down its own conduits, and rip up the streets at its own sweet will. It goes without saying that the proposition meets with very strong objection. The telephone people do not wish to be compelled to use such conduits, having a system of their own. The arc light companies, backed by the expert opinion of Mr. C. J. H. Woodbury, very much prefer to see their wires overhead, and the Edison Company, with its own elaborate and effective underground system, thinks that it, of all others, should be exempted. Thus we have a variety of sentiment on the subject; and the Boston Board of Aldermen, sitting as a committee of the whole to hear arguments pro and con., is becoming so learned that even the member who last year orated about the "ducks" in the conduits is not likely to repeat his mistake. Speaking of underground wires reminds me that in view of the work of the late storm it has been suggested in various quarters that at least a few trunk wires between the large cities should be placed underground to provide against such an evil emergency as that of last week. The alternative to this plan is found in the proposition to connect the three great cities of the Atlantic coast, Boston, New York, and Philadelphia, by means of submarine cables running along the coast. It is pointed out that by such a method communication could never again be entirely interrupted. It is not unlikely that some such scheme will be carried out. Another lesson of the storm was that trains as well as cities should be kept in communication, and I hear that the Edison-Phelps train-telegraph system was of very great use last week on one of the snow-blocked lines, in enabling trains and passengers on board to communicate with the terminus of the line.

Reports come from Buffalo of some fairly successful trials made there with an Elieson motor, imported from England, to give a demonstration of the merits of electric traction. The event was hailed with much interest, and the mayor and all the aldermen enjoyed a ride.

NOTES FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *3rd April*, 1888.

The future prospect of electrical lighting in Paris has not improved since my last letter, and in spite of long sittings of the Conseil Municipal for the last three weeks, during which that important matter has been repeatedly under discussion, there is still no likelihood of any company undertaking the starting of public electric light stations. No less than six important companies are ready to furnish the light to all the central parts of the town whenever the regulations of the Municipal body will permit, but unless the *cahier des charges* imposed upon the contractors be amended in its most important provisions, there will be no chance for the visitors to the 1889 Exhibition seeing anything else but gas in the streets of Paris.

It will be sufficient to give some extracts from this document to show the prohibitory nature of the conditions imposed. The maximum price for a 16 candle-power incandescent light is fixed at 4½ centimes per hour. The *employés* must never work more than nine hours per diem, and their minimum wages are fixed at 80 centimes per hour from 6 a.m. to 6 p.m., 1fr. 20c. from 6 p.m. to midnight, and 1fr. 60c. from midnight to 6 a.m.

A yearly payment of 100fr. for every kilometre of wire or fraction thereof laid in the public streets is to be made to the city, with a sum representing 5 per cent. of the gross receipts

Digitized by Google

of the company. But certainly the most absurd regulation is the following :—"The wiring will take the form of segments of a circle, going from the centre of Paris to the fortifications, and the companies must undertake to be ready to furnish the light to every part of their concession within four years." This regulation alone is sufficient to prevent any company from asking for a concession ; the distance from the centre to the fortifications varies from 6 to 10 kilometres, and if the consumers are pretty numerous within the 3 or 4 first kilometres, they will be very scarce for the rest, although the company would be bound to lay wires up to the last metre and to give light to the last house, even if it were only asked for a single lamp. The Conseil Municipal declares that it intends to fight the Parisian Gas Company ; but it has done quite the contrary, and apparently for a long time to come gas will still be the master.

The situation is better in the provinces, and instead of fighting against electric light the gas companies are themselves heading the revolution. Lyons, Marseilles, Toulouse, Clermont-Ferrand, Le Mans, Rheims, &c., see their gas companies preparing electrical plants, and the inhabitants of these cities and many others of smaller size will soon have the choice between gas and electricity.

CORRESPONDENCE.

THE GANZ WATTMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : The discussions which have lately been held about the wattmeter designed by me about four years ago, with a special view of using it for testing transformers, and the review of the pamphlet in your last issue are apt to throw discredit upon this instrument and those who use it in an undeserved extent. Though the objections raised by Prof. Ayrton and your reviewer against the accuracy of the wattmeter are based on a correct theoretical basis, they will yet not apply to the instrument under the conditions in which it is commonly used ; and I shall show that in the circumstances and the purpose the wattmeter was designed for, and hitherto used, its indications will come very near the truth. I shall also indicate how to make it an absolutely correct measuring device.

If r is the resistance of the fine-wire circuit,
L its self-induction coefficient,
r' and L′ corresponding terms for the circuit in which the power given is to be measured, and
$2n$ the number of current reversals per second,

then Prof. Ayrton's correction coefficient is

$$K = \frac{r}{r'} \cdot \frac{r r' + 4 n^2 \pi^2 L L'}{r^2 + 4 n^2 \pi^2 L^2}$$

(the current of the thin wire coil is supposed not to go through the stationary coil of the instrument).

This expresssion can be applied directly only when the whole power to be measured is really expended in the circuit under view itself ; while the *apparent values* for r' and L′ must be introduced into the formula when transformers or other apparatus are dealt with, in which secondary and Foucault currents and hysteresis of iron will consume energy outside of the thick-wire circuit, though supplied by the current pulsating in this.

A more general expression for the correction coefficient, and of which Prof. Ayrton's formula is a transformation, may be deduced in the following way :—

Let E and I respectively denote the square roots of mean squares of tension at terminals and current intensity for the circuit in which the power supplied is to be measured ; then this power is given by

$$E\,I \cos \lambda',$$

λ' being the angle of lag of the phase of current against phase of impressed E.M.F. at terminals of this circuit. This expression is true for any circuit whatever, provided we suppose E.M.F. and current to be sine functions of the time. If λ is the lag of phase of current in the fine-wire circuit of the wattmeter, then the reading of the instrument will be proportional to

$$E\,I \cos (\lambda' - \lambda) \,.\, \cos \lambda,$$

as may be shown by a simple calculus. The correction coefficient is therefore

$$K = \frac{\cos (\lambda' - \lambda) \cos \lambda}{\cos \lambda'} = \frac{1 + \tan \lambda \tan \lambda'}{1 + \tan \lambda^2} \quad . \quad . \quad (1)$$

and this will hold good in all cases.

For circuits which will not cause secondary currents or hysteresis of iron we have

$$\tan \lambda = \frac{-2\,n\,\pi\,L}{r} \text{ and } \tan \lambda' = -\frac{2\,n\,\pi\,L'}{r'},$$

which values introduced in the formula (1) at once transform it into that first indicated by Prof. Ayrton, having only a limited scope of application. Since tan λ is always a very small fraction, we may write

$$K = 1 + \tan \lambda \tan \lambda' \quad . \quad . \quad . \quad . \quad (2)$$

The wattmeter will therefore be a reliable instrument as long as tan λ tan λ' will remain a small fraction, say 1 per cent. as a maximum.

Now leaving circuits connected in any way with a condenser out of view, as the lag may there be exactly 90°, I have up to now never had opportunity of measuring power with a wattmeter in a circuit in which the lag between phase of E.M.F. and phase of current exceeded 87½°, with 100 alternations per second. Induction coils without iron must be of enormous size to get even at this value, while in coils with an iron core the Foucault current and hysteresis will prevent the lag from becoming sensibly equal to 90°. To take an extreme case let a standard 10 horse-power transformer, as manufactured by Messrs. Ganz and Company, be run on open secondary circuit with five times its normal tension and 200 alternations (2,000 volts and 83 alternations are the standard values), it would require 10,000 volts, take about 12 amperes, and the energy supplied wonld be something about 4,000 watts. The lag would amount to 88°. (When no hysteresis and no Foucault currents would take place, the angle of lag should be about 89° 58′.) But according to the instructions given in the pamphlet the fine-wire circuit should have in such a case 100,000 ohms. The self-induction coefficient of the movable coil of the wattmeter as actually made amounts to only 0·0002, and the correction coefficient with formula (2) becomes

$$K = 1{\cdot}000038\,;$$

while introducing $r = 250$ $L = 0{\cdot}02$,
directly $r' = 5$ $L' = 20$

into Prof. Ayrton's formula would give

$$K = 127.$$

Now, only figure 10,000 volts in a wretched resistance box of 250 ohms ! L = 0·02 is indicated in the pamphlet only to illustrate the calculus there made ; while 0·0002 is about the self-induction of a movable wattmeter coil of fifty turns of wire, enclosing about 60 sq. cm.

Well-made transformers run on open secondary circuits will make the current in the primary to lag about 50 to 70° behind the phase of the impressed E.M.F. In measuring the power supplied under such conditions with a wattmeter only a very small error will be incurred. I usually determine the energy consumed in the iron core of a transformer by supplying current to the secondary circuit, say at 100 volts.

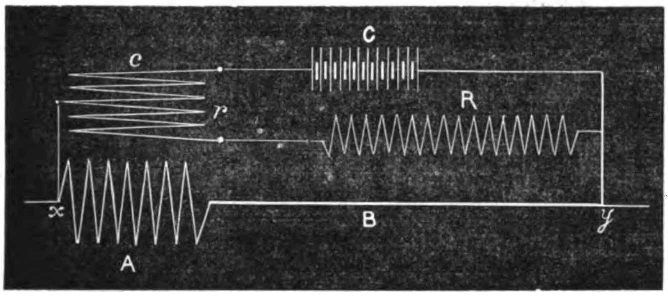
Then $r = 1000$, and usually $2\,n = 100$,
$\tan \lambda = 0{\cdot}0000628$ $\tan \lambda'$ about 2,
$K = 1{\cdot}00013$.

I am satisfied by these and other considerations that in no case in which I have used the wattmeter, or have advised others to use it, did the error due to the actions in view come near to 1 per cent. of the power measured. The introduction of the true values of r' and L′ in Prof. Ayrton's original formula in cases where this is not admissible, and the assumption of conditions so unfavourable to the wattmeter as will not be realised in practice, explain how very large "correction" coefficients may be obtained.

Digitized by Google

Should it be intended to use a wattmeter in cases where either λ' is very near 90°, or when a comparatively small resistance in the fine-wire circuit must be used, it would be easy to have instruments made with a large number of ampere-turns in the fixed coil and a smaller number of convolutions in the movable fine-wire coil, whereby the self-induction of this latter may be still considerably reduced, and a much wider scope of application given to the instrument.

An absolutely correct wattmeter can be made by putting two fine wires on the movable coil, the one connected up in the ordinary way in series with a non-inductive resistance, while the second fine wire is traversed by the charging and discharging current of a condenser acted upon by the same difference of potential as the fine wire resistance-circuit. This condenser circuit may also, besides the condenser and coil, contain additional resistances.



A thick wire coil of wattmeter,
B power consuming circuit,
r resistance fine-wire coil of wattmeter,
c condenser " " "
R non-inductive resistance,
C condenser.

It should be noted that the two fine-wire coils are connected up in inverse directions.

Now let i_1 be the current in r, and i_2 in c, then i_1 will lag a small angle behind the base of E.M.F., and i_2 will lag nearly 90°.

The reading of the wattmeter will be proportional to

$$\frac{1}{t}\int i\,(i_1 - i_2)\,d\,t,$$

i being the current in fixed thick-wire coil. To make the reading an exact measure of the power supplied to the thick-wire circuit, we must make $(i_1 - i_2)$ to have its phases synchronous with the phase of E.M.F. acting between λ and y. Supposing the two fine-wire coils to have equal numbers of turns in identical positions, the self-induction coefficient, as well as that of mutual induction, being L, the resistances of "condenser" and "resistance" coil circuits being also equal and r, then the capacity of the condenser should be

$$C = \frac{L}{r^2}$$

to satisfy the condition required for the instrument being a true wattmeter.

The constant of the instrument, however, will require a correction by

$$1 + \left(\frac{2\,n\,\pi\,L}{r}\right)^2,$$

which, for all practical purposes, is not worth consideration.

I hope, Sir, you will not consider this letter too long for your valuable paper, since it treats a matter of general interest, and will, I hope, assign to the wattmeter its deserved place in the list of scientific measuring instruments.—Yours, &c.,

OTTO T. BLÁTHY.

Albergo Milano, Rome, March 26, 1888.

P.S.—As you will easily see, there are some misprints in the transformed formulæ on page 506; K should there also be 127.

[It may be as well to add that the responsibility for the alegebraical error referred to in our correspondent's postscript (and also by Mr. Wilberforce) rests with the writer of the review, and does not in any way affect Prof. Ayrton's formulæ.—ED. *E.*]

THE FIRST USE OF ACCUMULATORS FOR ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of 17th February last, in the reproduction of Mr. Wm. Geipel's paper, read before the Institution of Mechanical Engineers, occurs this passage (speaking of accumulators as applied to electric traction):—"The problem was first attempted by Mr. Reckenzaun."

It is in no spirit grudging praise to a fellow-worker that I write this; those of us who have been pioneers in electrical locomotion can well afford to be accurate in the history of the various events forming historical epochs. Mr. Geipel has made a mistake. So far as this country is concerned, the first electric street car work was done at the beginning of 1882 on the North Metropolitan Tramways, under arrangements with that company made by me, and under my supervision. Some very important points were then ascertained in connection with accumulators on street cars.

Reference to these trials was made in the press early in March, 1882.

It was in the spring of the year following that the Electrical Power Storage car was operated at Kew.

But before even 1882—*i.e.*, in 1881—M. Philippart on the Continent had had cars running. No one conversant with the events succeeding the advent of the Faure accumulator can forget how much both accumulators, and consequently traction, owe to M. Philippart's energy and foresight. The first car run in this country was built abroad, and due to his work.—Yours, &c., RADCLIFFE WARD.

London, April 3, 1888.

THE SALE OF TELEPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As certain dealers in electro-magnetic telephones are utilising the newspaper reports of the recent case "The United Telephone Company *v.* The Equitable Telephone Association," as a means of pushing their business, pointing out that their instruments employ no *carbon*, while it is the *carbon* transmitter of the Equitable Telephone Association that is being specially attacked, it is well that the public should be informed that these said newspaper reports are in this case—as is frequent when the daily papers attempt to handle scientific matters—calculated to give very erroneous impressions.

As a matter of fact, the United Company are attacking the receiver used by the Equitable Telephone Association quite as much as the transmitter, and if their contentions can be upheld, all the "membrane" telephones now in the market are equally infringements.—Yours, &c. A. A. CAMPBELL SWINTON.

75, Queen Victoria-street, London, E.C.,
April 3rd, 1888.

THE O'KEENAN BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having read in your estimable paper what you say about my battery, will you kindly allow me to submit a few observations?

1st. As to cost of light. I have never given any figures, following my friend, M. Hospitalier's, advice not to do so, as inventors' tests are always thought to be "*sujets à caution.*" The only thing I may say is that the sulphate of copper battery is acknowledged by all electricians to be *the most economical of all.*

2nd. My battery is not, as said by the paper you mention, a portable one, as it generally weighs over half a ton.

3rd. I have never been consulted about the publication of the note in the "important provincial journal" you speak of.

4th. Up to the present time I have not seen one single English capitalist.

5th. I regret that you have not heard of my battery before; it has been described here in several electrical papers:—*L'Electricien*, 1st January and 3rd September, 1887, by M.

Digitized by Google

Hospitalier; *La Lumière Electrique*, 12th February and 19th November, 1887, by M. Marinovitch; *La Nature*, 27th August, 1887, by M. Hospitalier; *Journal des Arts et Manufactures*, by M. Delattre; *Bulletin International de l'Electricité*, &c. I take the opportunity of sending you the technical and practical description of my battery, written by me some months ago for Messrs. Mors, 8, Avenue de l'Opéra, my builders for France. These gentlemen have already, at their own expense and risk, made several installations of the O'Keenan battery, which give full satisfaction, having now been at work above six months, giving *regularly* when wanted *all* the light *required*.

We have in my father's house in St. Cloud a battery allowing us to have about 30 electric lamps, from 4 to 50 candle-power, in sitting room, dining room, bed rooms, stables, &c. The electricity produced by the battery is stored in twelve accumulators of 120 ampere-hours.

I would esteem it a favour if you would kindly publish these few lines in your largely circulated paper.—Yours, &c.,

C. ED. O'KEENAN.

St. Cloud, Paris, 31st March, 1888.

[Our correspondent does not enclose the description of the battery referred to. We should be pleased to receive it.—ED. *E.*]

FIRE OFFICE RULES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is whispered that the proposed new rules of the Society of Telegraph-Engineers and Electricians relating to electric light installations may not be materially different from those of the Phœnix Fire Office; if so, what possible purpose can their promulgation serve?

Moreover, the Phœnix rules are *copyright*, and there may be something to say on that score presently.

Will anything be gained by attempting to establish a kind of dual control? On the contrary, will not the beneficial effect of the moral sway hitherto exerted be seriously weakened or altogether destroyed? There has been a certain safeguard to the public in the fact that contractors have generally evinced a readiness to conform to the Phœnix rules, and as a natural consequence the class of work has been steadily improving, and the "cutting" firms have been finding it increasingly difficult to oust the truly conscientious contractors. If users of the light discover that there is need (real or imaginary) of a rival set of regulations, the growing confidence in this branch of electrical engineering will be shaken. If there be any necessity for revision or for enlarging the scope of the Phœnix rules, would it not have been possible to arrange a meeting of *representative electrical contractors* (upon whom the due execution of important works must fall, and not, I say it with all respect, upon the *consulting electricians*), at which Mr. Musgrave Heaphy, whose enthusiasm is admitted and to whom belongs the credit of compiling the Phœnix rules and bringing them in successive editions to their now complete form, might be present and conclusions arrived at satisfactory to all the parties concerned?

It is to be hoped that the members of the profession will insist that an independent committee be appointed by the Society to investigate and report upon the facts of this unfortunate dissension, and that such committee may invite Mr. Heaphy to give evidence and produce any correspondence that may have passed between himself and the Council of the Society on the subject, which is of the utmost importance and merits careful investigation.

It is perhaps a question whether the Council possesses the right to act in this matter without consulting the main body of members of the Society, and one thing is certain, viz., that scarcely a month will ever pass without the point involved being raised in some form or other, so that a settlement ought to be effected forthwith.

What we really need now is an efficient leader, and any one possessing the requisite qualities who will come forward at this juncture will earn the lasting gratitude of the whole profession.—Yours, &c., CONTRACTOR No. 3.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

4,453. J. SHAKESHAFT. Towcester. Improvements in railway signalling, which he names "Shakeshaft's automatic electric railway signal." March 23, 1888.

4,456. A. COLLINGRIDGE. London. An improved method of administering galvanic currents for curative purposes. March 23, 1888.

4,475. B. DUKES. London. Improvements in structures for supporting electric and other conduits, and for facilitating access to buildings (M. J. Hart, United States). March 23, 1888.

4,489. E. F. H. H. LAUCKERT and E. H. HAENSEL. London. An improvement in holders for electrical glow lamps. March 23, 1888.

4,523. J. KELMAN. Manchester. Telegraphic and telephonic apparatus, part being applicable to other electrical purposes. March 24, 1888.

4,524. W. J. S. BARBER-STARKEY. Manchester. Improvements in portable galvanic batteries. March 24, 1888.

4,559. F. DE WOLFFERS. London. Improvements in electric arc lamps. March 24, 1888.

4,561. C. A. BROWN. London. An improved battery jar. March 24, 1888.

4,568. S. WILLIAMS. Newport. Improvements in or relating to conductors for electrical and acoustic purposes. March 26, 1888.

4,579. J. J. DILLON. Dublin. A new or improved electrical apparatus for combining an electrical alarum with the ordinary mechanical alarum. March 26, 1888.

4,593. F. L. RAWSON and W. WHITE. London. Improvements in electrical batteries and methods of closing the same. March 26, 1888.

4,604. L. S. M. PYKE and H. T. BARNETT. London. Improvements in automatic apparatus for the continuous opening and closing of electric circuits. March 26, 1888.

4,626. C. HOEPFNER. London. Improvements in the electrolytic production of metals. March 26, 1888.

4,627. C. WELLS and F. J. GOAD. London. An improved method of using incandescent electric lights. March 26, 1888.

4,659. F. T. SCHMIDT. Bradford. Improvements in apparatus for making and breaking electrical circuits in connection with call or alarm boxes and recording the same automatically on dials. March 27, 1888.

4,673 P. M. JUSTICE. London. Improvements in and connected with apparatus for the generation and utilization of electric currents (C. Heisler, United States). March 27, 1888.

4,730. G. VENABLES. London. An electro-magnetic timepiece. March 28, 1888.

4,764. A. L. FRY. London. Improvements in portable galvanic and electro-magnetic batteries for medical purposes. March 28, 1888.

4,774. R. EISENMANN. Prussia. An electro-magnetic mechanism for pianos to strengthen and lengthen the sound of single notes, and to imitate the sound of other instruments. March 28, 1888.

4,804. E. J. PIPER. Northiam. A new switching arrangement for electric signalling, telephones, telegraphs, &c., by means of which any number of instruments may be worked on one single line one with the other. March 29, 1888.

4,819. W. G. JOHNSON. London. Battery for general electro-medical use, or as electrical dumbbells, Indian clubs, and the like for muscular exercise with electrical current of any desired strength during such exercise. March 29, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the dates in italics, give notice at the Patent Office in the prescribed form of such opposition.*

March 31, 1888.

4,220. J. W. KING, London. Improvements in instruments for measuring electric currents March 21, 1887.

4,447. P. B. ELWELL, Manchester. A new or improved apparatus for measuring, indicating and recording currents of electricity. March 25, 1887.

4,832. H. LIEPMANN, of the Liepmann Carbon Co. (Limited), London. Improvements in the manufacture and construction of carbon plates or electrodes for use in primary batteries, and for electro-metallurgical, electrolytical, and other electrical purposes. March 31, 1887.

14,768. C. M. DORMAN and R. A. SMITH. Improvements in the construction of switches for the making and breaking of circuits conveying electric currents. October 31, 1887.

16,351. A. OWEN. United States. Improvements in electric belts. November 28, 1887.

17,157. H. H. LAKE. London. Improvements in galvanic batteries (J. O. Whitten, United States). December 13, 1887.

SPECIFICATIONS PUBLISHED DURING THE WEEK.

3,158, 1887.—P. EVERITT. Giving currents of electricity for coin, &c. (Price 8d.)

5,140, 1887.—W. H. QUARTERMAN. Galvanic batteries. (Price 8d.)

5,193, 1887.—G. A. GRINDLE. Generating, &c., electricity. (Price 8d.)

6,267, 1887.—A. C. and THOMAS E. COCKBURN. Lock switches for electric circuits. (Price 8d.)

6,590, 1887.—W. H. SCOTT and E. A. PARIS. Magneto-electric cut-out. (Price 8d.)

6,933, 1887.—D. NICOLL. Insulating and laying electrical conductors, &c. (Price 8d.)

9,515, 1887.—E. WORMS and J. BALE. Tanning by electricity. (Price 8d.)

13,148, 1887.—F. ROSS and A. FRANZEN. Producing rectilinear or rotary motion by electricity. (Price 6d.)

13,447, 1887.—A. L. LINEFF and E. H. BAYLEY. Electric railways and tramways. (Price 1s. 3d.)

155, 1888.—A. J. BOULT. Eholing. Electrical turnstiles. (Price 8d.)

COMPANIES' REPORTS.

The Telephone Company of Ireland (Limited).

Report of the Directors, to be presented at the ninth ordinary general meeting, to be held at the offices of the Company, Commercial-buildings, Dame-street, Dublin, on the 9th inst., at twelve o'clock :—

The number of wires, exchange and private, under rental within the Dublin district and suburbs upon 31st December, 1886, was 915. On 31st December, 1887, the number was 936, being a net increase of twenty-one for the year.

The amount standing to the credit of net revenue account, including the balance of £329. 1s. 5d. brought from last account, amounts to £4,314. 3s. 6d., against £3,629. 2s. 4d. for the year 1886. Out of this sum there has been paid the interim dividend upon the preference shares for the half year ended 30th June, 1887 (£858. 19s. 1d. paid in July last), also the interim dividend upon the ordinary shares (£656. 5s. paid in August), leaving an available balance of £2,798. 19s. 5d., as shown in the balance-sheet, since reduced by payment (on the 14th January) of the dividend upon the preference shares for the second half of the year to £1,858. 6s. 8d., which the Directors propose to allocate as follows :—For the payment of a dividend on the ordinary shares for the second half of the year, at the rate of 1¼ per cent. per annum (absorbing £1,093. 15s.), against ¾ per cent. for the corresponding half of 1886, and equivalent to a distribution of 1 per cent. for the entire year, against ¾ per cent. for the year 1886, and to place to the credit of the reserve fund £398. 10s. 3d. (being 10 per cent. upon the net profits of the year), carrying forward the balance of £366. 1s. 5d. to credit of the current year, as against £329. 1s. 5d. brought in from 1886. In conformity with the Articles of Association, Mr. Hermann G. Erichsen and Alderman James Winstanley retire at this meeting, but being eligible, they offer themselves for re-election.

The auditor, Mr. John M. Kean, also retires at this meeting, but offers himself for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 30th, 1888, amounted to £4,315.

DIRECT SPANISH TELEGRAPH COMPANY.—Estimated traffic receipts for the month of March, 1888, £1,900, against £1,863 in the corresponding period of last year.

SUBMARINE CABLES TRUST.—The coupons of this Trust which became due on October 15th, 1887, will be paid in full on and after the 16th inst. by Messrs. Glyn, Mills and Co., of Lombard-street, between 10 a.m. and 2 p.m. Certificate holders are requested to present the October coupons only, and not those payable on April 15th.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 30th, 1888, after deducting the "fifth" of the gross receipts payable to the London-Platino-Brazilian Telegraph Company (Limited), were £3,491.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended March 31st, 1888, amounted to £4,175.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—Estimated traffic receipts for the half-month to March 31st, 1888, £3,703, as against £3,430 last year. December receipts, estimated at £5,577, realised £5,612.

ELLIOTT BROTHERS,

101 & 102, ST. MARTIN'S LANE, LONDON, W.C.

TELEGRAPH ENGINEERS AND MANUFACTURERS OF ALL KINDS OF ELECTRICAL TESTING AND TELEGRAPH INSTRUMENTS.

Submarine Mining Apparatus, &c. Contractors to H.M. Government.

SOLE AGENTS FOR THE SUPPLY OF SIR WILLIAM THOMSON'S NEW STANDARD ELECTRIC INSTRUMENTS.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 517.—Vol. XX. FRIDAY, APRIL 13, 1888. Price 4d.

NOTES.

We print elsewhere the full text of the "Rules and Regulations for the Prevention of Fire Risks arising from Electric Lighting, issued by the Society of Telegraph-Engineers and Electricians." It will probably be admitted by everyone that these rules are in themselves entirely acceptable —and yet it is difficult to see in what way their publication carries us any further forward, unless and until the Fire Insurance Companies also agree to abide by them. Meanwhile, the Society preserves its *amour propre* by the declaration that "it is to be understood that these general rules are not intended to supersede any detailed rules which Fire Offices may issue for their own protection." Just so; but is it not therefore obvious to ask *Cui bono?*

Coming to details we very soon find the inevitable permissive clauses, to which such strong—but as we think foolish—objection has been taken. In Rule 2 we read "The conductors, or their casings, should be placed in sight *if possible* [the italics are our own], and they should always be as accessible as circumstances will permit." In Rule 5 we read of "some suitable material," Rule 6 says that "special precautions must be taken," Rule 7 requires that conductors be kept "as far apart as circumstances will permit," Rules 8, 10 and 13 refer to certain undefined precautions—we need not further multiply instances. But this kind of thing is, as we have already remarked, simply inevitable, and does not militate at all against the value of the rules as such. But what it does conclusively prove is that some discretionary power must necessarily be vested in the Inspector. Who otherwise is to decide in any given case whether the "special precautions" are effective, or what is a "suitable material," or whether better arrangements are or are not "possible"? Contractors will do well to recognise these obvious facts at once; but whether or not any improvement can be effected in the methods of inspection or the qualifications of Inspectors is a question which requires consideration, but upon which we do not now propose to enter.

We have received from Mr. P. Delany, the inventor of the multiplex system of telegraphy now in use in the English Postal Telegraphs, a very lengthy communication which we hope shortly to have room to insert. We may here mention that Mr. Delany feels constrained to reply to certain statements and criticisms which have appeared in this country by or on behalf of M. La Cour, who claims to have discovered the principle of synchronism upon which the Delany multiplex system is based. These claims have already been fully and carefully investigated by a committee of the Franklin Institute, who have published an elaborate report upon the subject, accompanied by a number of letters from Danish, French, and German officials who have examined and reported upon the original work of La Cour. Their report has never been published *in full* in this country; if it had been Mr. Delany says he should not have thought it necessary to add anything in his own defence. We do not pretend to be fully acquainted with the whole of the details of this elaborate controversy; but, speaking from recollection only, the impression left upon our minds after reading the Franklin Institute report was that La Cour and Delany occupied positions jointly and severally analogous to those of Phillip Reis and Graham Bell—that is to say, La Cour undeniably had early possession of the idea that multiplex telegraphy was possible by means of some device for maintaining synchronism, and he worked in the right direction in trying to *maintain* synchronism by means of the so-called phonic wheel. Where La Cour failed—as it seems certain he did fail—and where Delany succeeded was in *obtaining* synchronism to start with, and in automatically *re-obtaining* synchronism whenever it was in any degree departed from. We have no desire to take part ourselves in this controversy either on one side or the other, but we are under the impression that the above statement describes the essential features of the case.

It may not be generally known that Mr. Crookes' very beautiful discovery of the "radiometer" has received a practical application in photography, for which purpose it is used in France in order to time the exposure of plates. By counting the revolutions of the radiometer it is evident that exposures of the same value may be obtained, under different degrees of illumination, with far greater accuracy than by depending upon the judgment of the operator. But in this country, where "instantaneous" plates have almost superseded the older methods, the radiometer has not, so far as we are aware, been employed for this purpose. In another column, however, we describe a most interesting development of the instrument due to M. Louis Oliver—to whom also is due the suggestion above described for its use in photography. M. Oliver has succeeded (it need hardly be said by aid of electricity) in causing the radiometer to produce a record of the number of its revolutions in a given time. This is, we believe, the first instrumental method of integrating the amount of luminous vibration falling on a given space, with

Digitized by Google

regard both to duration and intensity, and its introduction will probably tend to stimulate investigation in a field which has as yet been little explored.

ANYONE wishing to know the potential capabilities of telephonic enterprise should read our American correspondent's letter this week describing the progress that has been made in that country by the Bell Telephone Company. The exchanges of this company alone employ no fewer than 6,182 persons, and its subscribers number 158,732. Its long-distance service is being rapidly developed, the pole mileage already amounting 550 miles and the wiring to 10,000 miles. These trunk lines are spoken of as a success both electrically and commercially; and the Western Union Telegraph Company is beginning to regard them as a serious competitor—at all events to the private lines belonging to that company.

NOTWITHSTANDING these signs of prosperity, the shares of the Bell Telephone Company have been subject to sudden vicissitudes owing to the ticklish position of its patent rights. These rights, however, were firmly established by the recent decision of the Supreme Court, and it is simply amazing that the death of the Chief Justice, who drew up the judgment, should cause quotations to fall from $260 to $245. Gamblers, however, are proverbially superstitious, and it may be that some sinister omen unfavourable to the Bell interests was perceived in the sudden death of a learned judge who had just pronounced in their favour. If that be the explanation, American speculators may take fresh alarm if they hear of the "remarkable coincidence" to which a London electrical contemporary drew attention last week. We were told that in both the recent American case and the similar English case in 1882 the delivery of judgment was signalised by the death of the presiding judge *a few days after.* This is very alarming, if true; and if taken in the Voltairian sense, "*pour encourager les autres,*" might have serious consequences for the friends of the Bell patent.

BUT it is not exactly true; or, to put it more politely, the coincidence does not coincide. The judgment on appeal in the English case—which, by the bye, was delivered in 1883, not in 1882—was, indeed, followed by the death of Sir GEORGE JESSEL, who presided; but not until six weeks afterwards, the dates being respectively February 6 and March 21, 1883. To a certain class of mind these facts may be reassuring; and as touching the depression of American Telephone Stock in consequence of the death of Mr. Justice WAITE, if we are to imagine that the personality of a judge has anything to do with the legal decision he will pronounce, our own feeling would be one of congratulation that he lived long enough to pronounce in our favour.

Mr. ALBERT CAMPBELL has hit upon a very simple and, as he says, "a wonderfully accurate" method of timing deflection readings which are undergoing more or less rapid changes. We merely mention it in this place thinking that it may sometimes prove useful in laboratory experiments—a full account will be found further on in a notice of the last volume of the *Proceedings* of the Royal Society of Edinburgh. It requires, however, the aid of about ten different observers, which may sometimes prove a difficulty.

THE battle of the transformers is by no means yet at an end, nor can victory as yet be said to incline to either side. Indeed, it is not to be anticipated that any decisive advantage will be obtained in a merely wordy warfare of this kind, especially when, as in the present case, each of the contending parties is able to bring to bear so many distinctive features of merit on his own behalf, and can so easily and so comfortably ignore those adduced by his opponents. In this country Mr. CROMPTON has once again entered the field on behalf of his highly prized (we trust the compositor will notice that we write z, not c) accumulators; although, at the time of writing, the blow has not yet been struck. In a Paper read before the Electric Club of Chicago (which we hope shortly to give), Mr. SLATTERY endeavours to parry the attack of Mr. LEONARD, who, as our readers are aware, has presented himself as a champion of the three-wire system. By means of extracts from the authorised publications of the Edison Company Mr. SLATTERY attempts—with some success, as it seems to us—to confute his adversary, as it were, from his own mouth.

MEANWHILE, on this side of the water, a fourth combatant enters the lists in the person of Mr. PERCY SELLON, who this week appears in our own columns on behalf of the motor-generator. In his preliminary paper Mr. SELLON sets forth, with much vigour and not a little dialectic skill, the claims of this system of distribution. We are for several reasons glad to welcome a diversion of this character, for whatever may be the outcome, it will scarcely be denied that this highly interesting system has not hitherto received the attention it deserves. Comparatively little has yet been written on the subject—though by far the greater part has so far appeared in our own columns. Mr. SELLON will perforce labour under the disadvantage of advocating a system which has not yet received a practical application; but, on the other hand, he is not called upon to explain away any disastrous failures. It is true that EDISON has in progress, or has been reported to have in progress, an installation of this character at Llewellyn Park, but since the first announcement nothing further has appeared in the American journals. We hope shortly, however, to obtain some definite information from our correspondent in New York.

AFTER all, it is a pity that, in this country at any rate, the discussion is so much "in the air." A few definite figures obtained from a comparison, not of one, but of half-a-dozen different installations of each kind, would be worth a hundred columns of argument and estimates based upon assumptions which the opposing side can and always does pronounce inadmissible or unfair. Detailed statements of expenditure, such, for instance, as those compiled by Mr. WRIGHT for the Brighton multiple-series installation, and which were published in *The Electrician* of 30th December, 1887 (p. 178), would afford data

Digitized by Google

for really reliable conclusions. Possibly about the close of the century we shall be in a position to present such figures for the then surviving systems.

WITH reference to the convention entered into by the Chinese Telegraph Administration with the Eastern Extension and Great Northern Telegraph Companies, we are able to state that the particulars given in *The Times* on Monday last, and which we reprint in another coloumn, are substantially correct. The companies are to be congratulated on the completion of arrangements equally advantageous both to the foreign mercantile communities in China and to the companies themselves.

The Cost of Lighting the House of Commons.—Last year the cost of lighting the House of Commons amounted to £3,300 for gas, and £480 for electricity.

Bristol.—On Friday, June 8th, the oratorio of "Israel in Egypt" is to be given in the Cathedral at Bristol, and on this occasion the building will be lit throughout by electric light.

The Indo-European Telegraph Company.—It is announced that telegraphic communication with India, Turkey, &c., by the route of the Indo-European Telegraph Company, is restored.

Private House Lighting.—Messrs. B. Verity and Sons are electrically lighting "Mentmore," the residence of Lord Rosebery, and have also just completed the lighting of "Ascott House" for Leopold D. Rothschild, Esq.

Telegraph Extensions in Italy.—The Italian Minister of Public Works has authorised an expenditure of 139,000 lire (say £5,560) for the laying of a new direct telegraph line connecting Rome and Naples and Rome and Pisa.

The Patents of the Electrical Power Storage Company in France.—According to the *Bulletin Internationale de l'Electricité* the French patents of the Electrical Power Storage Company have been acquired by MM. Philippart Frères.

Tenders for the Lighting of Christchurch, New Zealand.—From a notice in another column, it will be seen that Christchurch, New Zealand, is following the recent example of Wellington in asking for tenders for electric lighting.

Edison's New Phonograph.—The first six samples of Edison's new form of phonograph will reach London in a few days, if they have not yet arrived. Colonel Gouraud proposes to present them to the principal crowned heads of Europe.

Inspector of Public Lighting.—We may call attention to the announcement in our advertising columns of a vacancy at Dublin for the post of inspector of public lighting to the Corporation, in which a knowledge of electricity is desired.

The Bray Electric Tramway.—An Order in Council is published in the *Dublin Gazette* authorising the construction of an electric tramway in Bray, from the Railway Station to the gate at the entrance to Bray Head, a distance of 1,500 yards.

Large Switch-Boards for Distribution Work.—We have been favoured with a view of the very large switch-board now being constructed by the United Electrical Engineering Company for the Aluminium Syndicate, and hope to give an illustrated description of it next week.

Army Signalling.—A school of instruction in army signalling for non-commissioned officers of Auxiliary and Volunteer Forces in the Home District, to be held Tuesdays, Thursdays, and Saturdays, from 6 to 8 p.m., will be commenced at the Signalling Office, Wellington Barracks, on Saturday, the 21st inst.

Electric Organ Keyboard.—The new concert organ which will contain some 3,500 speaking pipes for the Philharmonic Hall in Berlin is to be worked on an electro pneumatic system. There will be a movable keyboard, which will be connected to the instrument by a cable about 14 metres long, composed of 350 wires.

Carbons.—An American journal says:—"A new process of manufacturing electric light carbons or pencils and battery plates consists in decomposing natural gas under high heat and pressure, which gives a hard, very compact, and almost chemically pure carbon. It is then crushed, ground, and moulded in the usual way.

The Electro-Harmonic Society.—On Friday last this Society gave its concluding concert for the season; the programme was of the usual excellence. Mr. E. Graves, who occupied the chair, made a few felicitous observations, and concluded by proposing a vote of thanks to the musical directors, Messrs. Alabaster, Gatehouse and Thompson.

Tapping Telegraph Wires in France.—*La France* states that Count Dillon, managing director of the French Cable Company, has commenced an action against the *Matin* for robbery and divulgence of his private despatches. The *Matin* is said by some means to have secured and published the telegrams which passed between Count Dillon and General Boulanger.

Permanent Sample Room of British Products and Manufactures at Hamburg.—In connection with this excellent idea, a circular has been issued by the British Vice-Consul containing much information of interest to manufacturers. Applications for space for exhibits, or for copies of the circular, should be made to Mr. G. A. Pogson, British Vice-Consul, Colonnaden 104, Hamburg.

Church Lighting by Electricity.—The parish church of Blockley, a large village on the southern border of Worcestershire, is shortly to be lighted by electricity. The installation is being carried out by a company who have taken some old mills near at hand for manufacturing purposes, and the machinery will be driven by water power, of which there is an abundance available.

Norwich.—On Thursday evening last week a lecture was delivered by Prof. W. Barrett at Norwich "On Electric Power." The lecture was illustrated by numerous experiments, for some of which plant was lent by Messrs. Paris and Scott. It is needless to add that Prof. Barrett delivered a highly interesting and very lucid address, which was listened to with the utmost attention throughout.

Catalogue of Woodhouse and Rawson's Electric Supply Company.—The Woodhouse and Rawson Electric Supply Company have issued a second edition of their "Catalogue of Domestic Electrical Supplies," in which will be found quotations of retail prices of almost every conceivable requirement for the electrical fittings of a house, including electric bells in great variety, telephones, gas lighting apparatus and electric lighting.

Paris.—The French Minister of Finance has recently appointed a committee to study questions relating to the organisation of submarine telegraph systems. The chairman is the Director-General of the Postal and Telegraph Department. Amongst the members we notice the names of M. Ungeier, Head of the Central Office of the Postal and Telegraph De-

Digitized by Google

partment; M. Amiot, Inspector-General of the Postal and Telegraph Department, and M. Bélugon, sub-engineer of the same department.

A Central Station for Cologne.—The Town Council of Cologne have come to terms with the promoters of the central station for the business quarter of the town. The station is to be arranged for 6,000 glow lamps, but is to be capable of being enlarged to 12,000. The tariff is to be ⅜d. per 16 candle-power lamp-hour, with a yearly minimum of 350 to 500 lamp-hours, according to circumstances. The capital is to be £62,500, which will in the first place be offered to the citizens, in order to promote an effective control of the operations by the shareholders.

Eastbourne.—The report of the Lighting and General Purposes Committee of the Eastbourne Town Council contained the following resolution:—"That the account of the Eastbourne Electric Light Company for lighting the Town Hall for three months ended 25th December last be referred to the borough surveyor to report upon, and that it be a recommendation to the Council to pay the Eastbourne Electric Light Company the sum of £50 without prejudice, in respect of the supply of electric light for the Town Hall for the six months ending the 25th ult."

The Lewis Telegraph Cable.—In the House of Commons, on Tuesday last, Dr. M'Donald asked the Postmaster-General when it was his intention to have the telegraph cable between Lewis and the mainland, which had been out of order for several weeks, repaired; and whether, having regard to the large fishing interests of the island, which were mainly dependent for the sale of fish on telegraphic intelligence, he intended to lay a new cable instead of that now out of order.—Mr. Raikes said, in reply, that the cable ship belonging to the Post Office is at the present moment engaged in the repair of the Stornoway cable.

Electro-Technical Education in Germany.—An attempt is being made by the Frankfort Physikalischen Verein to establish an electro-technical school under its auspices, and a Paper read before the society by Herr E. Hartmann explains the aims of the project. Its object is not to increase the number of the scientists and engineers, but simply to provide practical scientific training for artisans. The course is to be one or two half years, and there will be an annual special course at the end of each winter, lasting only two or three weeks, on lightning conductors. In connection with the school it is also proposed to have a testing laboratory, and later on one for private original work.

Electric Traction on the Brussels Tramways.—In reference to the statement made in the report of the Brussels Tramways Company, which we quoted last week, that electric traction by accumulators had not hitherto been a success upon their lines, we have received a copy of a circular issued by the directors of the Société Electrique, by whom the batteries were furnished, which tends to put the affair in a somewhat different light. Without entering fully into the facts, it will be sufficient to state that the electrical company complains that since the purchase of the batteries it has not been consulted by the tramway company in any single instance, nor has its advice been followed. It also traverses the method in which the figures showing the cost of traction are arrived at.

Sheffield Telephone Exchange.—On Thursday, the 5th inst., the number of messages through the Sheffield Telephone Exchange reached the unprecedented number of 10,450, exceeding that of the corresponding day in last year by 3,598. Although the exchange is open night and day, and almost every profession, trade and calling is represented, the bulk of the work is done in five hours, *i.e.*, between 10 and 12:30 a.m., and 3 and 5:30 p.m. During these hours the capacities of the attendants and switch-boards are mostly tested—some of the attendants putting in communication as many as 720 subscribers per hour. There was an average for that day of over 20 messages per subscriber, the cost being less than a farthing per message.

Exports of Telegraphic Wire, &c.—The Board of Trade returns for March, and for the three months ended March 31, again show a falling off both for the month and for the quarter in the value of our exports of wire and telegraphic apparatus. The following is a comparative statement of the exports in the first quarter of this and of the two previous years:—

Exports of Telegraphic Wires and Apparatus connected therewith.

	1886.	1887.	1888.
January	£68,623	£14,442	£41,231
February	19,286	44,137	14,051
March ...	36,165	73,300	32,795
3 Months	£124,074	£131,879	£88,077

Compound Telephone and Telegraph Wires.—An old idea, first tried in America some years ago, has been revived, says *Industries*, by Messrs. Kareis and Bondy, Vienna, who have patented iron or steel wires covered with a spiral serving of copper wire or ribbon of very small thickness. These wires are now being tested at the laboratory of the Electrotechnical Institute in Vienna, and have so far given fairly good results. The object of the invention is to provide aërial wires having less self-induction and resistance than ordinary iron or steel wires, without sensibly diminishing the mechanical strength. The wire is intended for use with currents of rapid period, such as occur in telephony or in high-speed telegraphy, and as through self-induction the flow of current is displaced from the centre to the circumference, the inventors argue that it would be useless to make the centre of a material having a high conductivity.

The Royal Institution.—The following is a syllabus of a course of six lectures on the Chemical Arts to be delivered by Prof. Dewar, M.A., F.R.S., on each Thursday afternoon, from April 12th to May 17th, inclusive, at three p.m.:—Present Position of the Leblanc Soda Manufacture and the Sulphuric Acid Industry.—Development of the Ammonia Soda Process of Alkali Production.—New Methods of making Chlorine, Bleaching Powder, and Chlorates.—The Strassfurt Salts and Nitrate Industry.—Utilisation of Distillation Products from Coal, Shale, Coke Ovens, and Iron Furnaces; Recovery of Sulphur from Alkali Waste; Uses of Iron Slags. —The Soap Industry; Glycerine; Glass Manufacture.—Industrial Uses of Compressed Gases; Organic Explosives; Oil and Water Gas; Petroleum as a Fuel; Lubricating Oils.—New Sodium Process; Electro-Metallurgy.—Electric Furnaces; Cowles' Aluminium Bronze Manufacture; Electric Welding; Bleaching and Treatment of Ores.—Production of Artificial Organic Compounds.

The Electric Lighting of the Vienna Opera House.—According to the Vienna correspondent of *Industries*, the Imperial Continental Gas Association are still experiencing some trouble in connection with their electric lighting installation in that city. Writing on the 3rd inst., he said:—"Some alterations are being made in the central station from which the Opera is supplied. When the steam dynamos were first erected, the

Digitized by Google

vibration communicated through the walls to the adjoining buildings was so great that in some rooms it was impossible to write, and the owners of the property commenced legal proceedings, with the result that the Imperial Continental Gas Association was ordered to discontinue the nuisance on a penalty of 5,000fl. for each infringement of this order. To overcome the difficulty, the association have laid down an enormous foundation block of concrete, on which the dynamos are placed. This block is completely detached from the walls of the building, so that no vibration of any kind will be communicated to the neighbouring houses."

Central Station Work in Portugal.—The new central station of the Companhia de Luz Electrica, Oporto, was inaugurated on the eve of the 31st ult. This company has for some time past supplied a small number of lamps from five dynamos of various and antiquated patterns, and of English, French and German origin. The inferior construction of the machinery and general installation was the cause of irregular supply, and the company therefore intrusted Mr. F. Baerlein, of Rua da Prata 40, Lisbon, with the erection of entirely new plant and building. The inauguration took place with the customary festivities, and the general design of building, as well as machinery and plant, earned the highest praise from all present. The station is designed for an extreme capacity of 3,000 lamps, but only the first section is yet completed, the remainder being added with all possible speed. The installation presents considerable novelty in the general arrangements, most of which have been specially designed by Mr. F. Baerlein, and partly executed in England, partly in Lisbon.

A New Current Meter.—Prof. R. Bœrnstein, of Berlin, has devised a current meter of novel construction. It consists (1) of a dynamometer, whose indications are proportional to the current intensity; (2) a planimeter which integrates the deflections of the dynamometer. The axis of rotation of the movable bobbin is placed at an angle to the vertical, and the proportionality of the deflection is obtained by a very ingenious device. A sector is affixed to the axis, and is balanced by a small weight attached to a cord which runs over a couple of pulleys. The form of the sector is so adjusted that the movement of the weight is always proportional to $\sin a \tan a$, a being the angle of deflection; and it can be shown that under this condition the tangent of the angle of deflection will be directly proportional to the current. The rotation of the axis of the coil displaces a disc over which a wheel moves in such a manner that its velocity is proportional to the angular displacement of the disc. The number of turns made by the wheel is registered by a train of clockwork. The apparatus is evidently available either for continuous or for alternating currents.

Electric Lighting of Spanish Theatres.—As far back as the 18th November last we referred to the proposal to make the lighting of the Madrid theatres with electricity compulsory, and in our last issue we were able to state that definite terms had been published in the Madrid *Gazette*. Spanish papers to hand since bring details of the regulations, according to which we observe that installations must be completed within six months from 1st April. During the first three months licenses are to be applied for and prepared, and during the last three months installations and machinery must be completed. Theatrical managers may use a private light generated on the premises, or may take the light from companies which are already established, or which may be established in the future. Incandescent lights must be used in the interior of the theatres, with the exception of the stage, on which permission will be given to use the arc lamps in order to produce the effects of the Drummond light, now strictly prohibited. Outside the theatres the arc lamps may be used. As the use of gas is strictly prohibited, oil lamps (olive oil) may be used as supplementary to the electric light.

The Relative Cost of Gas, Oil, and Electricity in Russia.—Before imposing the recent duty of one copeck a pod on kerosine, the Russian Minister of Finance appointed a committee of experts to collect information as to the relative cost of gas, oil, and electricity in the two capitals, in order to determine whether the proposed tax would have an injurious effect on the petroleum industry. The data supplied, says *Engineering*, was of course very elaborate, as Russian official statistics always are; but without reproducing the details, we may say that, roughly, the price of gas and oil at St. Petersburg differs very slightly from that prevailing in London, while electricity is somewhat cheaper. Reckoning the price of kerosine at 1 copeck, the relative cost of other methods of lighting at St Petersburg was as follows:—Gas, 3 copecks; electricity, 7·3 copecks; and stearine candles, 22·9 copecks; while at Moscow the proportions were—gas, 6·2 copecks; electricity, 10·4 copecks; and stearine candles, 34·4 copecks. In this manner oil was three times cheaper than gas at St. Petersburg, and six times cheaper at Moscow. One can hardly wonder, therefore, at its gaining ground in both places.

Kensington Electric Lighting.—At the last meeting of the Kensington Vestry the Works Committee reported that, in compliance with the reference by the Board of the 10th ultimo they had considered the copy of the draft license by which it was proposed to authorise the Kensington Court Electric Lighting Company to construct and maintain electric lines and works, and to supply electricity within the parishes of St. Mary Abbotts, Kensington, and St. Margaret, Westminster, and, after conference with the engineer and the solicitor, had instructed the latter to suggest the following alterations to the Board of Trade:—In clause 7 (section C), authorising the carrying of the line over or across any street, the addition of the word "bridge." In clause 10, relating to interference with any sewer, drain, watercourse, defence, or similar work under the jurisdiction or control of the Board, the insertion of the words, "or work in connection with such sewer or drain, such as ventilating shafts, manholes, side entrances and gullies;" also a provision that any consent given by the Board should be in writing. The committee requested the sanction of the Board to the course they had taken. The report was approved.

Berlin.—The Khotinsky Company of Rotterdam have established a central station in Neue Friedrichstrasse, Berlin. Ten-year contracts are already entered into for six 1,000 candle-power arc lamps, 12 of 500 candle-power, and 550 16 candle-power 150-volt glow lamps. The plant at present consists of 45 horse-power boiler, 35 horse-power engine, a dynamo for 150 volts and 130 amperes, and a set of accumulators for 150 volts, and having a capacity of 600 ampere-hours. The capital, we understand, is to be £3,000, which is to allow for a second engine and boiler and foundations for another dynamo, the staff consisting of one engine driver and one stoker. The connections from the mains to the houses are made at the company's expense, and the current is measured by Aron's meter. A further addition of 300 glow lamps will shortly be made; the capital will then be increased by £500 to provide for the mains and second dynamo, while the staff will be increased by one whole boy. Any further extension will require a new cable and second battery equal in capacity to the present one, and, let us hope, another boy. The capital will then be increased to £5,000! We beg to state we are not responsible

Digitized by Google

for these remarkable figures, but extract them from the *Elektrotechnische Zeitschrift.*

Football.—Cable Companies versus Channel Squadron.—A correspondent writes:—On Saturday, March 24th, a football match was played at the Eastern Telegraph Company's station, Carcavellos, Portugal, between a team selected from the staff there and a team composed of officers from the various vessels of the Channel Squadron, then anchored in the Tagus. The weather was unpropitious, the rain falling heavily during the whole contest, but it had no effect in damping the ardour of the players; and, although the ground soon became very heavy and slippery, the men seemed to gather fresh strength from their frequent contact with Mother Earth. A capital and exciting game was played, but, despite the gallant efforts of the staff team—of the forwards, Messrs. Spriggs and Wray specially distinguishing themselves—fortune inclined to the naval men, who scored seven tries to *nil.* This result, however, was scarcely to be wondered at, the team from the squadron being composed, without exception, of full-grown, heavy men, who contrived by their style of play to reap all the advantages conferred by their preponderance of weight. After removing the traces of the struggle, the teams adjourned to their dinner in the staff mess room, which was followed by a very enjoyable musical evening. Team as follows:—Freeman (back), Master (capt.), Hurtler and Morris (three-quarter backs), Fraser and Lyall (half-backs), Penrice, Wray, Spriggs, Dupuis, Lawson, Paine and Dowthwaite (forwards). Besides those mentioned above Mr. Hustler played well.

The Lighting of the Hotel Ponce de Leon, St. Augustine.—The Hotel Ponce de Leon, at St. Augustine, Florida, contains one of the largest isolated electrical plants in the world. It consists of four Babcock and Wilcox multitubular boilers working up to 107 horse-power nominal each, four Armington and Sims engines, three of 60 horse-power, and one of 125 horse-power. Each of the 60 horse-power engines drives a 640-light Edison dynamo, and the 125 horse-power engine drives two No. 16 Edison dynamos. The plant supplies some 5,500 incandescent lights in all, and "feeders" are employed as in the Edison method of distribution. In connection with this installation, the *Scientific American* says that Mr. Flagler is trying the experiment of obtaining motive power from an artesian well. The well throws up a column of water 35ft. high and 12in. in diameter. Directly over the well is a large turbine wheel; bolted directly to the shaft of this wheel is a 375-light Edison dynamo. As far as steadiness and constancy of the light are concerned, the trials have proved eminently satisfactory; but the power obtained has not been so great as was expected. This is chiefly due to the method in which the stand pipe is connected with the turbine, and to the arrangement of the paddles in the wheel, which allows a great proportion of the water to pass by. Changes are being made to remedy this, and it is then intended to run all night with the hydraulic plant alone. Contrary to the anticipations of experts, the flow of the water has remained constant for three months. The experiment is, we believe, the first of its kind on record.

Lighting of ss. "Paula."—The ss. "Paula," built for the petroleum trade by Sir W. G. Armstrong, Mitchell and Co., at Low Walker, has an installation of electric light by Rankin Kennedy, of Glasgow. The dynamo is one of Kennedy's single bobbin machines, capable of supplying 70 16 candle-power lamps, running at a speed of 750 revolutions per minute. The motive power is derived from a Tangye's "Archer" type vertical engine, and the dynamo is driven by means of a canvas gutta-percha belt from the fly-wheel. In the whole ship, with the exception of the saloon and officers' quarters, specially protected conductors, insulated with vulcanised india-rubber, and sheathed over all with galvanised iron wires, are used. The joints in these conductors are protected by specially designed malleable cast-iron joint-boxes, and the whole arrangement makes a very substantial job, calculated to withstand any amount of rough usage without injury. This is of the greatest importance in petroleum-carrying vessels, where the conductors require to be specially secure on account of the nature of the trade. The fittings in the saloon and cabins are of neat designs, in harmony with the other fittings of the ship. The globes are of pale pearl, and give a particularly pleasing tone to the light. Throughout the whole ship, wherever light is required, the electric light has been carried, and arrangements are also made, and portable lamps with long flexible leads provided, for carrying the light down into the tanks when they require cleaning out or inspecting. The masthead, side, and anchor lamps have also been arranged for electric light. We understand that the same firm are engaged fitting out the "Caucase," another vessel for the same trade (recently launched by the same builders), and they are putting electric light on two passenger steamers for the Chinese coasting trade, now building at Messrs. Hawthorn, Leslie and Co.'s.

Electric Light in Dublin.—The Corporation of the City of Dublin are advertising under the Electric Lighting Act, 1882, their intention to apply to the Board of Trade for authority to supply the city with electric light. They ask for liberty for this purpose "to open and break up streets and bridges, to alter the position of gas and water mains, pipes and wires, sewers and drains under the same; to acquire lands, to appropriate lands, to construct such works, acquire such licences, to enter into such contract, and to do all such acts and things as may be necessary and incidental to such supply." The proposed area of supply is the city without limitation of any district. The streets in which it is proposed to place electric lines are, to start with, Sackville-street Upper, Sackville-street Lower, O'Connell Bridge, D'Olier-street, College-street, College-green, Westmoreland-street, Grafton-street, Island Bridge-road, Sarah Bridge, Conyingham-road, Parkgate-street, Albert-quay, Sarsfield-quay, Ellis's-quay, Arran-quay, Inns-quay, Ormond-quay Upper, Ormond-quay Lower, Bachelor's-walk, Dame-street, Parliament-street, Grattan Bridge, Capel-street, Mary-street, and Henry street. These are specifically enumerated in the application, and in order to carry out the works the Corporation further desire to have liberty to break up the tramway lines through the city. The application for a licence, says the *Irish Times*, for the supply of electricity for public purposes raises the question of public lighting in a new and interesting form, and it is one to which the citizens are bound to give instant attention. Reference was made to the subject of lighting by the Lord Mayor in the speech on practical topics which he delivered at the High Sheriff's dinner. The allusion was direct enough. "Will you say, Mr. High Sheriff (said his lordship), that the condition of the public lighting of the City of Dublin is in such a condition in which it ought to remain? I appeal to the High Sheriff with confidence, because I am aware that no personal relation in which he stands can affect either the keenness of his intellect or in public affairs the impartiality of his judgment. I say that neither in regard to cost, nor the character nor the control, is the system of public lighting in Dublin satisfactory." Thus appealed to, the High Sheriff stated that, though a director of the gas company, he believes that the supplying of light to the city should be under municipal control.

CONTINUOUS-CURRENT TRANSFORMATION.

BY R. PERCY SELLON.

At a time when electrical engineers, both in England and America, are anxiously discussing what system of electrical distribution is to be looked to as likely to fulfil the requirements of supply of electricity over large areas, it may be well to inquire into the latent possibilities of a system which has hitherto received but an intermittent kind of attention, and even that to a large extent with a sceptical incredulity—that of distribution by continuous-current transformers, or "motor-generators," as they are sometimes called.

The continuous-current transformer has really not yet been taken *au serieux.* Quite recently it was included among other possible systems of distribution, and figures adduced which showed it to compare unfavourably with distribution by alternating currents, yet not so unfavourably as that by means of secondary batteries, or "battery transformers." In spite of this, the conflict of opinion lies between alternating currents and batteries, and continuous-current transformation is left out in the cold.

It is intended in these articles to glance at the subject—

First: In respect to relative merits and disadvantages when compared with other systems.

Second: To survey the past history of the continuous-current transformer, touching upon patents and publications relating to it, up to date.

Third: To examine afresh its position from the practical standpoint, viz., that of initial cost.

The past ten years, within which period all commercial electric lighting, under whatever system, has been condensed, have witnessed successively the following developments:— First, series supply; second, multiple arc; third, series-multiple; fourth, secondary battery supply; fifth, alternate-current transformation.

Until but a few years ago—one might almost say a few months—the first four systems absorbed all the attention of electrical engineers.

Despite the earnest advocacy of "series" distribution by at least one well-known firm of manufacturers, electrical engineers have turned a deaf ear to this scheme as being likely to afford the true solution of the problem before them.

"Multiple arc" has had, and in all cases where the area of supply is limited and compact is likely to have, a long and successful innings. A visit to any town of reasonable magnitude in the United States will readily convince one that under the above conditions "multiple arc" distribution—mainly on the three-wire system—answers sufficiently well both technically and financially.

But, unfortunately, in this country, compact areas demanding electric light are not to be found. The "Britisher" does not build his houses so high nor adopt a good thing with the same avidity or unanimity as his American cousins. The conditions are, therefore, different.

"Series-multiple," as a method of extended distribution for domestic purposes, requires no comment.

Admittedly, therefore, there are left but three systems which may be regarded as able to fulfil the requirements of practical distribution over all areas. They are:—

(I.) Distribution by secondary batteries alone, acting as transformers.

(II.) By alternate current transformation.

(III.) By direct current transformation.

For the moment these may be compared with reference to their relative values in the following directions:—

(*a*) Adaptability to various demands: light, power, and storage.

(*b*) Reliability of operation.

(*c*) Efficiency.

(*d*) Freedom from danger to life.

Dealing first, then, with the system of secondary batteries used as transformers.

Secondary batteries can hardly yet be said to have been thoroughly put upon their trial for purposes of distribution. The installations at Colchester and the Vienna Opera have been the nearest approach to such a state of things, but the former, for well-known reasons, was short-lived, and the latter, though electrically successful in every way, only partially satisfies the conditions that must obtain in extended practice, inasmuch as the local centres of supply are few in number, and the charging current sensibly large compared with the demand from the batteries at each local centre.

Now, as regards the disposition of secondary batteries in any system of supply, it is evident that the scheme of distribution by their means from local centres must find favour with practical electrical engineers in preference to that of installing them upon each consumer's premises.

There are two difficulties which must be coped with in any complete system of battery transformation:—

First: In order to preserve the discharging low tension supply from the full tension of the primary current in case of leakage, charging and discharging should not be carried on concurrently.

This entails the use of two distinct sets of batteries.

Second: The conditions of charge being those of high E.M.F. and small current, and of discharge the reverse of these, the batteries must be charged in sets placed in series with one another, and such sets thrown into parallel for the discharge. This entails a considerable number of relatively small-sized batteries, and a consequent arrangement of more or less complex automatic devices.

These considerations, however, involve no insuperable difficulty of any kind, but simply involve the question of increased first cost arising out of multiplication of parts.

In respect to adaptability to the demands of both lighting and motive power, this system answers well; and in regard to reliability, absolute immunity from danger of extinction, and freedom from personal risk of shocks, leaves nothing to be desired.

Distribution by alternate-current transformation is having it very much its own way just now. It is the idol of the hour. Ushered into existence only comparatively a few months ago with incredulity and even derision on many sides, the tide of electro-public opinion has turned with prodigious rapidity, and lifted it upon a rock of great, apparently, for the moment, of impregnable strength.

The advantages of the system speak for themselves. The extreme simplicity of the apparatus for converting the initial high-tension primary current to one of low tension; the entire absence of moving or delicately organised parts requiring frequent attention; the perfect self-regulating properties of the transformers when placed in parallel; the high efficiency of conversion under certain conditions—all these constitute advantages which must at once recommend themselves to any practical electrical engineer.

But this system lacks two important properties which are to be looked for in any ideal system of distribution:—

(I.) The ability to store power;

(II.) Economical supply of motive power.

As regards the former, it is certain that, whether secondary batteries are advocated as the means of transformation, or only as an adjunct to low-tension supply obtained by other means, a system which admits of storage must, other things being equal, have unhesitating preference accorded to it.

That the application of motive power to a variety of purposes will promptly arise out of the ability to procure it must be carried home in the most convincing manner to any one who has seen, as it has been the writer's good fortune to do recently, the remarkable development in this direction attending the establishment of central stations in the United States. It is needless to say that this utilisation of plant during hours when it would otherwise be lying comparatively idle is a source of revenue of an important character; so much so, that, as the writer was informed upon the highest authority, it has frequently been the means of converting a loss on working to a substantial profit.

Digitized by Google

Alternating-current motors cannot yet be said to be an accomplished fact. That the demand for them will create, and is in process of creating, a supply there is no reason to doubt. Nevertheless, where the conditions of operation are those of rapidly varying load or speed (as must frequently be the case in practice), it is difficult to anticipate an economical compliance with the demand.

"But," it is urged in favour of this system, "despite its shortcomings in the above directions, it possesses this unique feature which neither battery transformers nor continuous-current transformers can claim, that by its means electricity can be conveyed direct to each consumer's premises without the intermediary of local centres and the attendant outlay on land, buildings, distribution mains, and skilled attendance. It is therefore a system which can be put to work straight away, with a minimum of obstruction from Electric Lighting Acts, shilly-shallying Boards of Works, and vested-interest vestries." Granted. So long as the existing arrangement of overhead wires is permitted, this argument possesses great force. But this blissful state of things must be short-lived. The time cannot be far distant when all conductors will have to be placed underground ; and, as a matter of fact, it is more than probable that any electrical engineer contemplating the laying down of a system of alternate-current distribution would at this moment hesitate to provide for any but underground conductors.

Under the latter conditions it requires no prophetic eye to foresee that the initial outlay, the danger of general leakage, the risk of shocks despite all precautions, and the cost of maintenance, arising from a ramified system of conductors conveying high-tension currents to the door of each consumer, will probably be held to more than balance the disadvantages attendant on the establishment of local centres.

Assuming this, the balance of *pro* and *con.* for the three systems becomes largely readjusted. The factor of local centres and distribution mains—both heavy items in initial outlay—becomes common to all. It resolves itself, then, into a question for consideration between the high efficiency of conversion, the relatively smaller area required for plant, and consequently smaller local centres, and to some extent diminished skilled attention, belonging to the alternate system, on the one hand, as against the benefits arising out of greater security from use of storage, income derivable from supply of motive power, and diminished risk of leakage and shock which pertain to continuous-current supply, on the other.

The main objections raised against the continuous-current transformer resolve themselves into the following :—

First : that it is a piece of moving mechanism ; and this fact is not only fatal to its domestic adoption, but enables it to compare but ill with the stationary alternate converter.

Second : that it is a disproportionately high-priced article in contrast with the alternate converter, and will cost more to maintain.

Third : that its efficiency of conversion can never reach that of the latter.

Let us examine these objections :—

Firstly. Nobody will be so hardy as to dispute that our national education has not yet brought James or Abigail up to the point of being likely to view with any composure the diurnal lubrication or adjustment of a revolving dynamo wherein many hundred volts are urging on their wild career. There is no disguising this fact ; it means local centres for distribution.

But the opinion has already been expressed that, whatever the system employed, so long as high-tension currents—say, of 1,000 to 2,000 volts—are made use of, it will be expedient to distribute the low-tension supply from local centres ; and, once given local centres, it ceases to be a matter of primary importance whether the transformers are in motion or stationary. A local centre for 2,500 lights, obtained from continuous-current transformers, need not mean more than a cellar, 12ft. square ; and since the transformers are perfectly self-contained, the mechanical strains being all from within and not external, no elaborate precautions need be taken as to solidity of foundations or surrounding structure.

As to attendance, a single engineer would have no difficulty whatever in attending to the requirements of such a sub-station, even were the transformers built on the lines of our present dynamos—without any special precautions as to automatic lubrication and collection of current—and less attendance than this could hardly be provided under any system for supplying an equivalent capacity in electrical energy.

Secondly. As to the relative outlay requisite on the two different classes of transformer, it is obvious that if the continuous-current apparatus is built in accordance with the existing notions as to axial or peripheral speed holding in dynamo construction, its cost will be many times as high as that of the stationary alternate converter ; but the very fact that in the former all the strains are from within, removes any scruple to run them at far higher speeds than now obtain for dynamos, and thus bring the relative cost of the two classes of apparatus much more on to a par.

Obviously, this is only one of several difficulties to be met, and improvements to be effected, upon our present crude ideas of continuous-current transformers ; but the point is, that there is nothing inherently obstructive to their development in every direction to be desired, and this fact has only to be faced to produce a due result.

Thirdly. On the point of efficiency of the continuous-current transformer *per se*, there is no difficulty at the present moment in obtaining a commercial efficiency of over 90 per cent. As to the relative mean efficiency of the two complete systems in practice, including generating dynamos, conductors, and transformers, when working through the 24 hours on large variations of load from hour to hour, it is not a rash proposition to hazard that the continuous-current system would be found at the end of the day's work to have given a satisfactory account of itself.

More than one mind in this country is already busied with the development of the problem of which it has been attempted in these notes to point out some of the leading features, and at a period of rapid evolution of ideas like the present some practical outcome may be confidently looked for. In any case it is desirable to thresh out all that may be said on each side before settling down into a fixed groove.

In the next article it is proposed to refer to the more important patents and publications which have appeared relative to the continuous-current transformer ; and finally to examine into the probable outlay required for the supply of electricity to a given area under each of the four following systems :—

(1.) Battery transformers.
(2.) Alternate-current transformers.
(3.) Continuous current transformers.
(4.) Continuous-current transformers and batteries combined.

(To be continued.)

A PROPOSED NEW PUBLIC TELEPHONE SYSTEM FOR CITIES AND LARGE TOWNS.

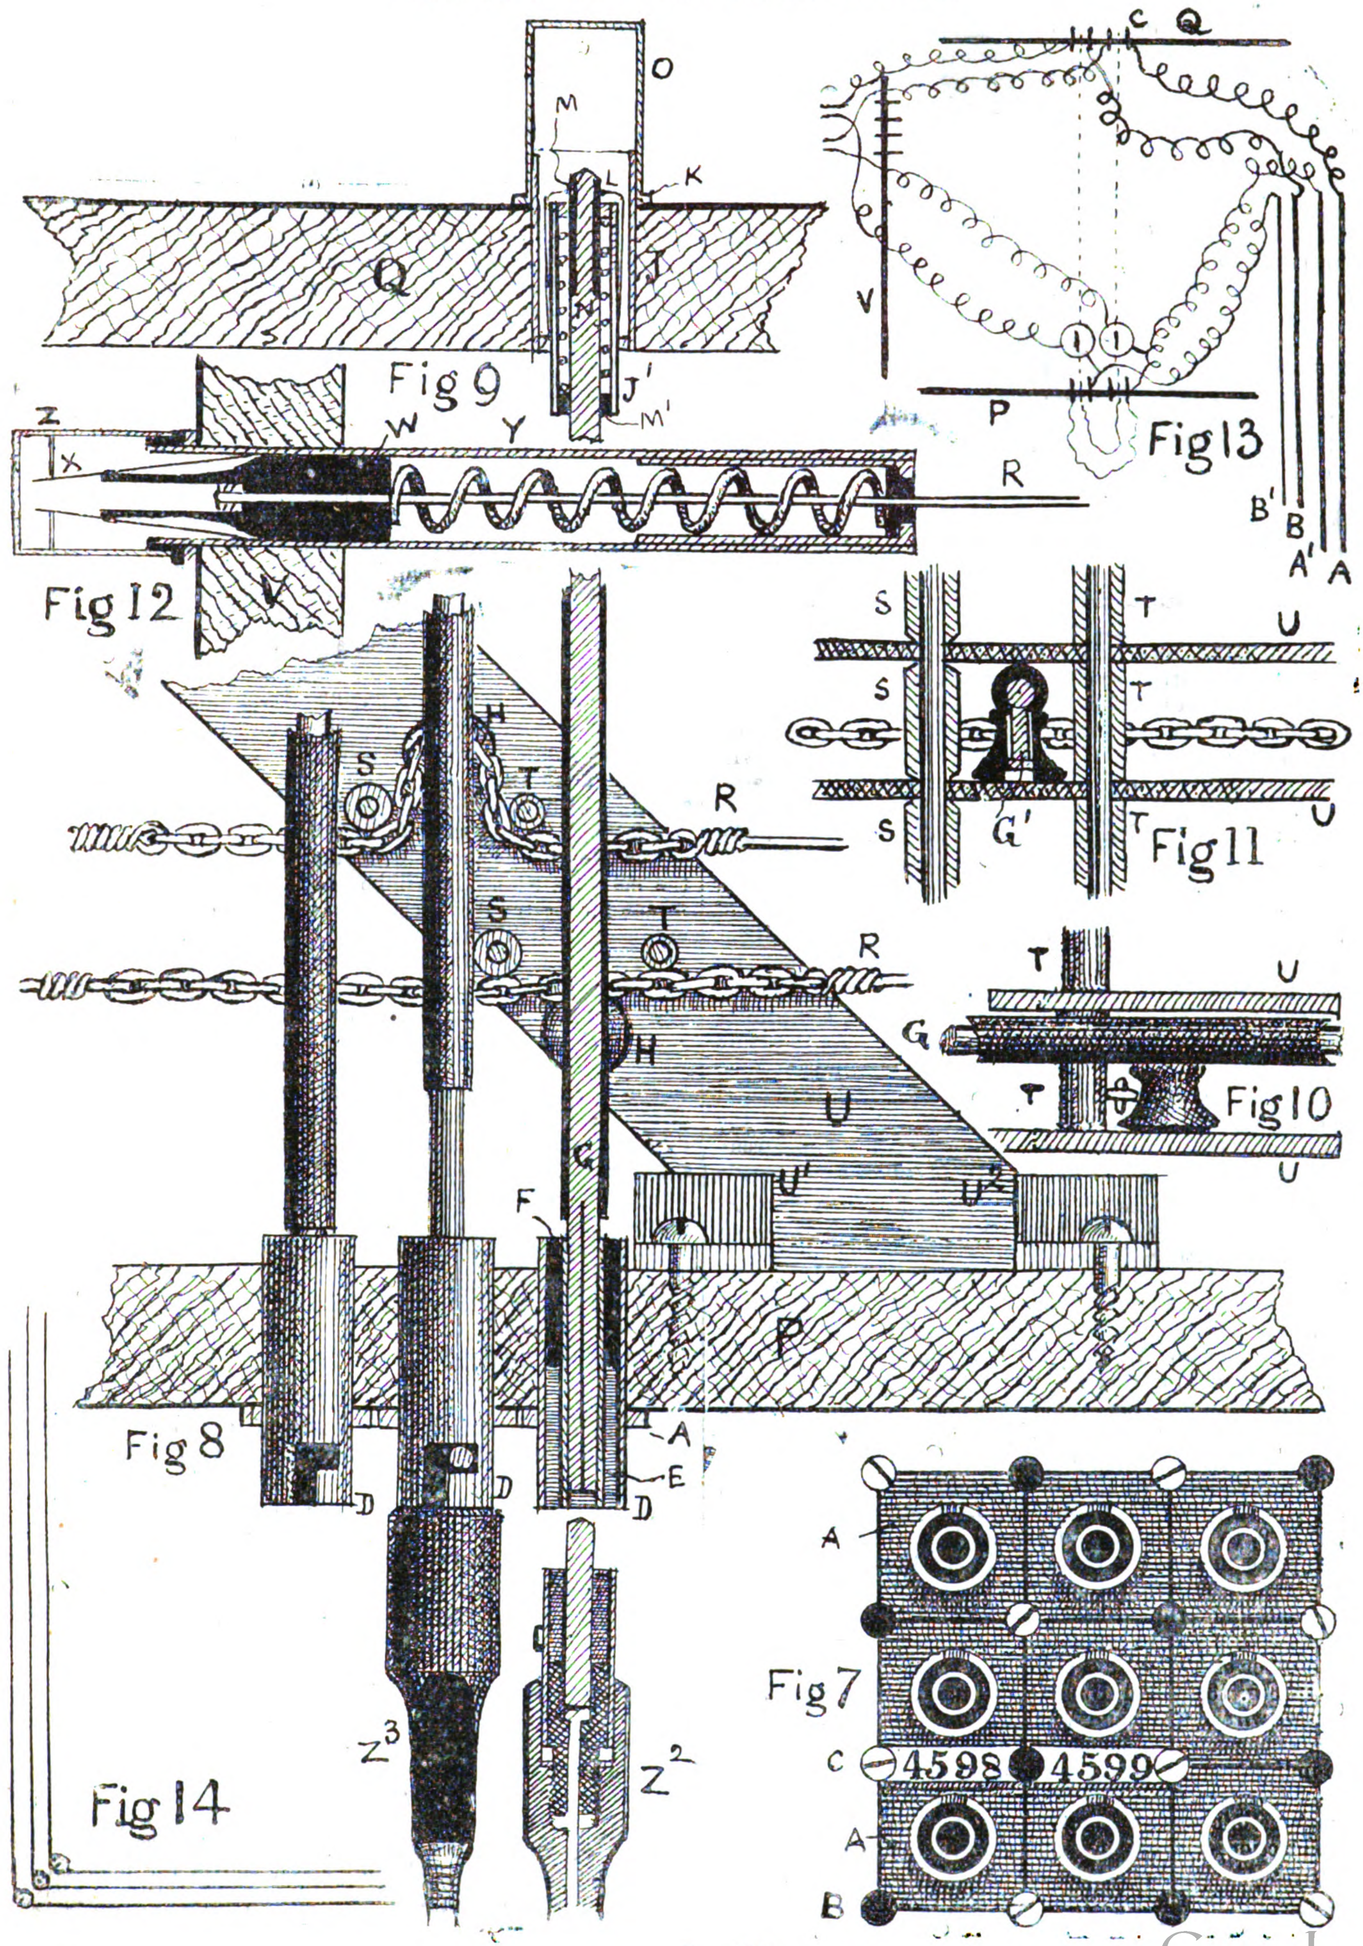
BY WALKER MOSELEY.

(Continued from page 542.)

Next to the insulation of the wires the switch apparatus in telephone exchanges has caused most trouble and annoyance, and has latterly been the subject of numerous inventions, of which the most successful is that of the "multiple" switch-board. The object of these multiple switch-boards is that by their aid an operator may ascertain whether a certain number is disengaged, and can connect the same to any other without asking any question of any other operator. This is done by a system of sound signals, and still calls for some care and attention. The multiple switch that I have recently designed goes far beyond this in responding to all practical desiderata. It is based upon the principle of a lock, in so far that when an operator connects any given number to another, the apparatus, repeated on every other operator's board, is

Digitized by Google

PROPOSED NEW TELEPHONE SYSTEM.



locked against access to those two numbers. In other words, if a certain number is *dis*engaged, any operator can connect to it without asking any question, or listening, or looking for any signal. But if it is engaged the switch plug, instead of entering freely, meets with rigid resistance, which not only means "engaged," but leaves no opening for interruption or eavesdropping.

The illustrations give nearly all the details of the apparatus by which the operations are effected. They are very nearly full size, with the exception of Figs. 13 and 14, and will be understood by the following descriptions :—Fig. 7 represents a small portion of the front of the operator's board, showing the connections for nine lines. A A, &c., are square metal plates, to which the tubes D, &c., are soldered. The plates are fixed to the board P (Fig. 8) by the screws C. The tubes D are insulated from the smaller tubes E by the ebonite insulator F, to which both are fixed. Inside the tube E is an iron rod, which extends through the back terminal board Q (Fig. 9). A tubular double-cased spring box, J J^1, keeps the back end of the rod in position. It is insulated from the spring box by the ebonite tube M and collar M^1. A square flange, K, is soldered to the outer tube, and at two corners—diagonally, as at Fig. 7—it is fixed with screws to the line terminal board Q.

The rod G is drawn in its normal position, in which position it is insulated from the line which is attached metallically to the spring box J J^1, of which O is a cover, but when the switch plug Z^2 is pushed home, as shown by Z^3, the portion of the iron rod which is covered by the ebonite tube M is carried beyond the tubular comb springs L, and the ends of the springs rest on a silver collar at N. Metallic contact is thus made with the iron rod G and the inner tube E, in the operator's board P. When this movement is performed the ebonite pulley H, which rotates on a strong round peg, G^1 (Fig. 11), fixed to—or really part of—the rod G (Figs. 8, 10, 11), engages the chain R, and carries it forward between the roller S and fixed pillar T. This movement of the chain has the following effect :—Being terminated at the right hand (beyond all the operator's boards) by fixture to the dead end board, and on the left by attachment to R (Fig. 12), the action described compresses the coiled spring in the tubular box Y (Fig. 12). As therefore each chain has only a certain allowance of slack it can be engaged by only one operator at once. Between each horizontal series of rods and chains, there are plates, U, fitted to the boards P and Q by grooved clamps, U^1, U^2. The spaces between each are accurately fixed by these grooves and by the pillars T, shown in section in Fig. 11. The pillars T and the rollers S are kept in position by steel wires running vertically through the whole vertical series. The spring boxes Y (Fig. 12) are fitted to the chain terminal board V, and are insulated from the covers Z. There are tubular comb springs, X, soldered to these spring boxes which, when the ebonite pieces W are in their normal position, as drawn, are kept in contact with the metal covers Z, by pressure against the inner edges of a hole through silver discs soldered to the cover Z, as shown in section Fig. 12. When any given number is engaged as described, the circuit previously completed by this contact spring X is interrupted, and the current, instead of travelling from line terminal board at K, Fig. 9, to Y, on chain terminal board V, Fig. 12, and through the connection to the cover Z, and thence to indicator (over operator's board) and to the return wire, the current travels from line terminal board, through the iron rod to E on operator's board, P, and through switch cord to any number that the other end of cord is connected to. These circuits are set out in Fig. 13, A and B being two lines, and A^1 B^1 being the return wires, P, Q, and V being the operators, line terminal, and chain terminal boards respectively.

The indicators are represented as being cut out of circuit when the lines are "put through," but it will be obvious that they may be left always in circuit by a slight change in the wire connection, without any alteration in the construction of the apparatus.

The springs in the spring boxes on line terminal board are auxiliary to the springs at chain terminal board, in order that by their direct pressure the rods G may be returned to their normal position with less actual force than would be required if the springs on board V were the only ones used. Hence the operator has less force to counteract than he would have in the latter case, and the operations do not cause fatigue or unpleasantness. The iron rods G are covered with ebonite to prevent any of the chains from making accidental contact. The front and back boards P and Q are kept accurately in position by strong stay rods in place of every 225th number, or, in other words, a stay rod for about every square foot. Indeed, each square foot may be a separate piece, all the pieces for one set forming one large panel in a strong frame. In case of accidents or wear and tear each hole through either the front or back board is notched to the depth of the diameter of the rod G, so as to allow the pulley H to pass through. In very large switch-boards, such as are required for more than 3,000 subscribers, it may be thought desirable to introduce guide rods and plates for some of the rods G on the left of the plates U (Fig. 8), in which case a partial repetition, with slight modification of the arrangement of plates U and upright wires S and T will suffice.

There are several other mechanical methods available for utilising the above described action of switch-locking, but any other would require too much space on account of having in large exchanges to turn one or two angles, as shown at Fig, 14, where the chain action requires only a small pulley for each chain. The numbering on the operator's board is provided for by slips of ivory long enough for two numbers, each pair of numbers being fixed between and under the heads of screws C, Fig. 7. The alternate pairs of corners, as at B, represent holes through which pairs of wires are passed to attach under the plates A. The illustration shows that the plugs Z^2 Z^3 fit into bayonet joints.

Although several matters of detail, more or less important, are omitted in the above description, it represents substantially the main features. It will be seen that there are no effective means for electrical connection to the front of operator's board, unless the switch plugs are pushed quite home.

As I have made no reference to any means by which the operator may "cut in" to ask what number is wanted, or whether any given pair of subscribers have done speaking, I may mention, without detail, that I propose to connect all the subscribers whose indicators are under the surpervision of a given operator to spring connections arranged in vertical series right and left of the operator, so that the pressure of any given button will open the corresponding circuit and put in circuit the operator's instruments. When the operator is asking for the number he will have a switch plug in hand ready to put in the number asked for, so that the reply, whether such number be engaged or not, may be almost instantaneous.

THE ELECTRIC LAUNCH "LADY COOPER."

We give illustrations this week of the electric launch "Lady Cooper," which, as we have already reported, made its first run on the day of the University boat race.

The launch is constructed of steel, and was built by Messrs. Redpath and Paris, of Limehouse, to the designs of the Electrical Power Storage Company. It is fitted with 66 cells of the latest T, or traction type, made by the E.P.S. Co., in which all the improvements of their "1888" type are embodied.

The cells contain 23 plates, and are capable of giving a discharge up to 40 amperes, and have a capacity at that rate of about 175 ampere-hours ; at a lower rate of discharge the capacity is considerably greater.

The motor was designed expressly for the boat, and gives efficiencies at the various powers of half speed to full speed, of from 78 to 85 per cent. It is somewhat heavier than is usually considered desirable, but the greater efficiency overcomes any objection of this kind. At full speed the motor makes 500 revolutions per minute, and is capable of efficiently working a screw of 24in. pitch

Digitized by Google

The majority of the cells are placed under the floor, which is somewhat below the water line, the remainder being placed under the seats, which run along on either side of the boat. The starting gear, which is of a peculiar design (intended for tramcars as well as boats), enables the batteries to be coupled in series or in two parallels to the motor, giving an E.M.F. of either 66 volts and 18 amperes when in parallel, or 130 volts and 36 to 40 amperes when in series. The motor works with an almost entire absence of sparking under all conditions either of full speed or half-speed. The brushes are fixed in such manner that going either ahead or astern no attention beyond the movement of the switch lever is required.

Fig. 1.—The Electrical Power Storage Company's Electric Launch, "Lady Cooper."

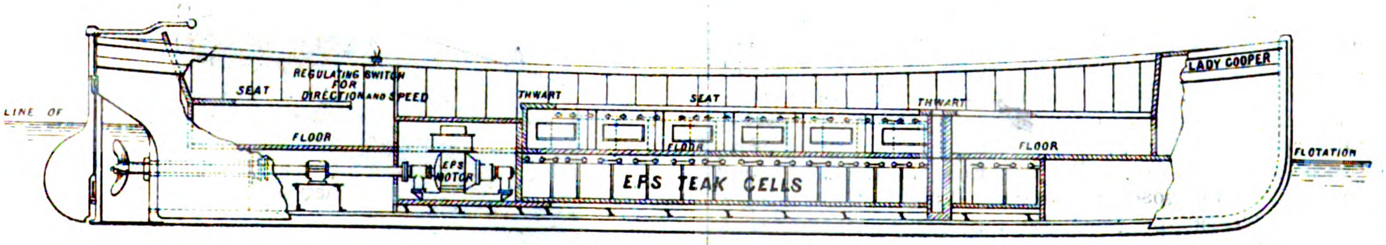


Fig. 2.—Longitudinal Section.

This boat is to be fitted with a cabin about 7ft. long, and will have an electric gong in place of the ordinary steam whistle as an alarm. It will be provided with a search light in

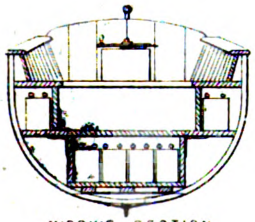

Fig. 3.

case it should be used for police purposes, and will also have a wheel in place of the present tiller, and with the experience gained it is hoped that still better results than the present speed of about 11½ miles on a tideway will be attained.

Fig. 1 is engraved from a photograph which was taken at Putney on the day of the boat race. Figs. 2 and 3 are longitudinal and midship sections.

TELEGRAPHIC COMMUNICATION BETWEEN CHINA AND EUROPE.

The United States Minister to China in a report to his Government describes a convention recently concluded at Chefoo between the representatives of the two telegraph companies having cables landed in China and the Chinese telegraph administration. The convention has created some alarm among the foreign mercantile communities in China, and has not yet been ratified by the Chinese Government, although the agents of the cable companies concerned spent the winter in Pekin for the purpose. Colonel Denby explains that the Great Northern Telegraph Company of Copenhagen and the Eastern Extension Company of London have divided the territory in China. The lines of the former run north through Japan to Vladivostock and Eastern Siberia, while the English company's lines run south through Singapore and India. Telegraphing to and from the interior is done over the Chinese lines, and, under arrangements hitherto existing, the Chinese telegraph administration received 50 cents per word for messages sent abroad from the interior. Under the arrangement proposed by the convention the Chinese would receive 70 cents. The companies, says the Minister, charge cable rates, although most of the service is by land. The following are the terms of the convention :—It sets forth that the Chinese telegraph administration intends to connect its system with the telegraph lines of adjacent countries, that the two companies also have this connection, and that it is desirable "to avoid competition." It is, therefore, agreed that all the traffic exchanged between any part of China, excepting the three ports of Shanghai, Foochow, and Amoy, on the one side, and Europe (Russia excepted) and countries beyond, on the other side, and *vice versâ*, transmitted by the land lines of the Chinese administration, whether by the land

Digitized by Google

frontiers or the cables of the two companies, shall belong to the administration. For this traffic a terminal charge of 5 francs 50 centimes a word shall be fixed by the administration and shall belong to it. The like rate shall be fixed for all traffic exchanged by the land lines of the administration *viâ* the land frontier between Hong Kong, Amoy, Foochow, and Shanghai on the one side, and Europe (Russia excepted) and countries beyond, on the other side, which shall belong to the two companies, subject to a deduction of 10 per cent. of the receipts of the companies as hereinafter specified. The companies shall fix their rates on the traffic thus exchanged between Hong Kong, Amoy, Foochow and Shanghai and Europe, and the countries beyond, except Russia, by their cable routes *viâ* Siberia and India, at 5 francs 50 centimes per word, which shall belong to them, less the payment of the above-mentioned 10 per cent. The proceeds of all messages from and to the four ports mentioned, whether by the land lines or cables, shall belong to the companies, who shall pay 10 per cent. to the Chinese administration. When the land lines are interrupted for a period not exceeding 60 days the traffic may go over the cables without charge. The administration shall fix the rate for all traffic out of China at 5 francs 50 centimes per word. Government telegrams shall pay full rates, and no percentage shall be allowed thereon. The tariffs and payments fixed by the agreement shall not be changed unless by mutual consent. The parties to the agreement shall do all in their power to prevent the transmission of messages by any person or corporation at rates lower than those fixed, and neither party shall be interested in any other company, by sea or land, to the detriment of either of the others. The cables shall not be extended to any place in China or Corea without the consent of the Chinese administration, but existing land rights shall be preserved. The agreement is to take effect from the day that the administration shall connect their lines with the telegraph lines of any adjacent country in telegraphic communication with Europe, and shall be in force until May 19th, 1903. The American Minister says the substance of this agreement is that China will receive about $150,000 per annum more than she now gets, while the advantage to the cable companies is that for sixteen years they will have no serious competition. He does not regard the agreement as containing any principle of monopoly, because any one may lay cables to China from any part of the world. The two companies are rich, and consider that by cutting rates they can kill foreign competition. But in this it has to be observed that as the Chinese are a party to the agreement, they can prevent any enterprise of this nature by refusing to allow cables to be landed on their territory. The rates fixed in the agreement contain a slight concession to the general public, there being a reduction of 50 cents per word. But foreign merchants demand that the price be fixed at $1 per word. The companies, however, take the ground that no man telegraphs except when compelled to do so, and that their business would not be increased if the rate were reduced to $1.—*Times*, April 9th, 1888.

A PROPORTIONAL READING GALVANOMETER.*

BY DR A. D'ARSONVAL.

A genuine commercial galvanometer must be direct reading. Mirror instruments are very valuable for delicate research and measurement, but their place is, above all, in the laboratory. Direct-reading galvanometers have, as a rule, the defect of not giving deflections proportional to the current intensity. The maker is obliged to graduate them empirically, which complicates their construction very much, and at the same time increases the chances of error arising from graduation. For these and other reasons every new method allowing electrical instruments to be read direct constitutes a progress.

This question has occupied me for many years. In 1882 I found a solution, which is embodied in the apparatus shown in Fig. 1. This ammeter was made for me by M. Ducretet, and was exhibited at the Société de Physique in 1883 or 1884. Until now I had not thought of making it more public, because the use of mercury made it of little practical use; but recently I have overcome this defect as here described.

* *La Lumière Electrique*, 24th March, 1888.

The apparatus shown in Fig. 1 comes under the category of moveable-circuit galvanometers, which I brought into practical use in 1881 by adding to Deprez's "herring-bone" galvanometer the modification now known under the name of the Deprez-d'Arsonval galvanometer.

This ammeter can only be used for measuring strong currents. It has the advantage of giving proportional indications whatever may be the deflection, even if it exceeds 360 degrees.

The principle upon which it depends is that of the rotation of currents by magnets. A horse-shoe magnet, A, rests horizontally on three levelling screws; on one of the poles there is a vertical iron cylinder, C, hollowed out at the top and filled with mercury. The base of this iron cylinder is surrounded by a circular basin, D, which is of hard india-rubber, and has its circumference graduated. This basin is filled with mercury, which does not touch the iron cylinder, but which is in connection with it by means of a pillar, shown in the figure.

The other pole carries a vertical rod, along which slides a projecting bar, F, supporting the movable parts carrying the current. This arrangement is a simple metal bridge, B B′, consisting of two large copper wires, united at the top by a bar, and kept apart at the bottom by a ring carrying an index moving along the scale on the basin. The cross-bar at the top has a copper rod at the centre which dips into the mercury in the cylinder cup. This apparatus is suspended from the arm F by a metallic wire, E, which is at the same time suspension and torsion thread.

If one brings a current to the terminals of the apparatus shown in Fig. 1 it will be seen that the current enters at the basin D, ascends the movable conductor B B′, goes down the column C, and leaves by the magnet A.

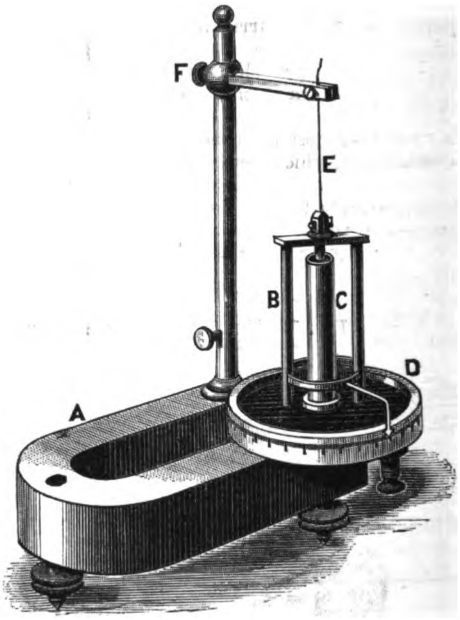

Fig. 1.

The well-known laws of electro-dynamics show that the movable conductor must turn continuously round the central magnetic pole C, the couples remaining the same whatever the position of the conductor B B with respect to the magnet C. This, in fact, is what would happen if the parts B B′ were pivoted; but, thanks to torsion thread E, this movement is limited, B B′ turns until the couple due to the torsion of the thread E balances the couple caused by the passage of the current.

The torsional couple is proportional to the angular deflection, on one hand; and since the moving couple is constant and independent of the angle of rotation, it will be seen that the deflections are strictly proportional to the current intensities, whatever the angle of deflection. The sensitiveness of the instrument depends, all things being equal, upon the diameter and length of the thread E, which may be very thin, since it only suspends B B′. The magnetic pole C may be replaced by an equivalent solenoid, but the instrument, as I have said, is by no means sensitive.

The great defect of this arrangement, which caused me to reject its use, was chiefly the impossibility of increasing the length of the circuit traversed by the current, and consequently the sensitiveness of the apparatus. The current ought to have the same direction in the two parts of the movable arrangement, which prevents us rolling it up into the form of a multiplier, as is done in the case of the so-called unipolar machines.

I succeeded in getting round this difficulty last year by the arrangement shown in Figs. 2 and 3.

Digitized by Google

I take a tube of soft iron (Fig. 2), which I magnetise powerfully by attaching it to the south pole of a strongly magnetised sheaf, S. The conductor traversed by the current is rolled into the form of a frame, one of the sides of the frame coinciding with the axis of the magnetised soft-iron tube. This part of the conductor is thus screened from the action of the lines of force of the magnetic field. Moreover, I take this side of the frame as axis of rotation, by suspending it by means of two metallic threads placed one in prolongation of the other.

As in the Deprez-d'Arsonval instrument, these threads serve as conductor to the current, axis of rotation and torsional couple balancing the motive couple due to the passage of the current in the frame.

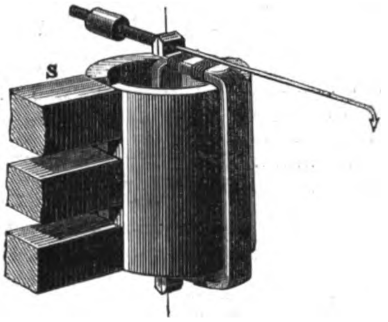

FIG. 2.

The upper part of the frame carries an index needle and counterweight, balancing the frame on its axis of rotation. By these means we are able to multiply the effect of the current to any desired degree, and yet obtain the conditions of the apparatus shown in Fig. 1.

The movable frame can describe nearly an entire circle; it is only stopped by the magnet S, which prevents it completing a revolution.

Fig. 2 is only a theoretical arrangement to make plain the principle of multiplication applied to the unipolar instrument. In reality, I greatly intensify the magnetic field by giving it an annular form. For this purpose the second pole of the magnet is bent concentrically round the iron tube, so that the movable part of the frame moves in a circular magnetic field of great density. Fig. 3 represents one of these arrangements. The magnet is of the Gower type.

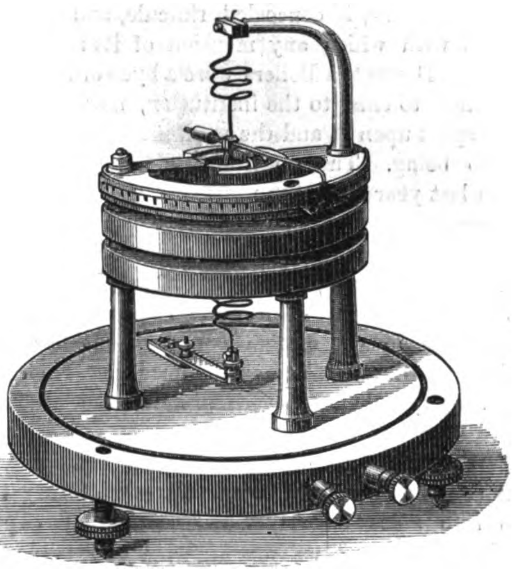

FIG. 3.

One of the poles carries the soft iron tube, the second pole terminates in another soft iron tube surrounding the first. The frame is suspended by two spiral springs or helices. We thus have an apparatus with deflections rigorously proportional up to 180°. If necessary it can be easily used up to 300°, but that is generally of no use.

It is not necessary for me to say that this instrument is absolutely dead-beat, and that it possesses all the valuable qualities which caused electricians to adopt the Deprez-d'Arsonval instrument.

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-DAY) FRIDAY, April 13th.

PHYSICAL SOCIETY OF GLASGOW UNIVERSITY.

Paper on "Force and Energy." By Mr. W. WALLACE.

SOCIETY OF ARTS.

8 p.m. Indian Section. "The Experiences of Twenty Years in conducting Agricultural Inquiries in Southern India." By Mr. W. R. ROBERTSON, M.R.A.C., Principal, College of Agriculture, Madras. Chairman, Sir JAMES CAIRD, K.C.B.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper on "Joy's Valve-Gear applied to Locomotives." By Mr. H. H. CARRICK, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Lecture, "The Pygmy Races of Men." By Prof. FLOWER.

PARKE'S MUSEUM OF HYGIENE.

8 p.m. "Ventilation, Measurement of Cubic Space, &c." By Sir DOUGLAS GALTON, F.R.S.

SATURDAY, April 14th.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Later Works of Richard Wagner" (1). By Mr. C. AMBRUSTER.

PHYSICAL SOCIETY (LONDON).

3 p.m. "On the Measurement of the E.M.F. of Dynamos." By Prof. W. E. AYRTON, F.R.S., and Prof. J. PERRY, F.R.S. "On the Variation of the Coefficients of Induction." By Mr. W. E. SUMPNER, B.Sc. "Some Experiments on Soap Bubbles." By Mr. C. V. BOYS. "On Electromotive Forces by Contact." By Mr. C. V. BURTON, B.Sc.

MONDAY, April 16th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture V. "Milk Supply and Butter and Cheese-Making" (2). By Mr. RICHARD BANNISTER.

TUESDAY, April 17th.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. "A Hundred Years' Progress in New South Wales." By Mr. W. F. BUCHANAN, J.P. Mr. B. FRANCIS COBB, Chairman.

ROYAL VICTORIA HALL (Waterloo Bridge-road, S.E.).

8 p.m. Prof. GEO. HENSLOW on "Movements of Plants."

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed, "Compressed Oil-Gas and its Applications." By Mr. ARTHUR AYRES, M.Inst.C.E. Paper to be read, time permitting, "The Distribution of Hydraulic Power in London." By Mr. E. B. ELLINGTON, M.Inst.C.E.

ROYAL INSTITUTION.

3 p.m. Lecture, "John Ruskin" (2). By Dr. C. WALDSTEIN.

WEDNESDAY, April 18th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Telescopes for Stellar Photography." By Sir HOWARD GRUBB, F.R.S.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Meeting at the Institution of Civil Engineers. Papers to be read:—"Jordan's New Pattern Photographic Sunshine Recorder." By Mr. JAMES B. JORDAN. "On the Meteorology of South-Eastern China in 1886." By Mr. WILLIAM DOBERCK, Ph.D., F.R.Met.Soc. "Lightning in Snowstorms." By Prof. A. S. HERSCHEL, M.A., F.R.S. "Insolation." By Mr. RUPERT T. SMITH, M.Inst.C.E., F.R.Met.Soc.

THURSDAY, April 19th.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Chemical Arts" (2). By Prof. DEWAR.

CHEMICAL SOCIETY.

8 p.m. Meeting.

ROYAL SOCIETY.

4:30 p.m. Ordinary Meeting.

FRIDAY, April 20th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "The Speed Trials of the latest addition to "The Admiral" Class of British War Vessels." By Mr. DAVID S. CAPPER, M.A. Stud.Inst.C.E.

ROYAL INSTITUTION

9 p.m. Lecture, "Antagonism." By the Right Hon. Sir WM. R. GROVE, M.A., LL.D., F.R.S., M.R.I.

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

ANSWER TO CORRESPONDENT.

CHEMIST.—*You can obtain a practical acquaintance with electrical engineering at either of the City and Guilds of London Technical Colleges, or at the School of Electrical Engineering, Princes-street, W., or at some of the colleges in the North of England. In the United States there are several excellent schools, notably the Technological Institute at Boston, and the Cornell University at Ithaca, N.Y. You must not, however, imagine that a certificate from any one of these institutions will "ensure the student remunerative employment." The fact is that the profession in this country is already overcrowded with mediocrities, though there is always room at the front for men of undeniable merit. The States present a far better opening for the average electrical engineer at the present time. It is difficult or impossible to obtain instruction in an engineer's shop without paying a premium.*

SOUTH KENSINGTON.

Matters at South Kensington, it appears, are still a long way from being established on a satisfactory footing; and the undefined suspicions, ill-concealed ridicule, and outspoken disparagement with which any mention of its name used to be met when the Brompton Boilers were a byeword of mismanagement continue to cling to the institution, notwithstanding the vast sums spent upon it and the magnificent edifice they have called into being. These sentiments found some practical expression last year when the project of an Imperial Institute was set on foot, and would perhaps have proved fatal to it but for the energetic efforts of its Royal patron, and the loyal support of Colonial brethren, who are not infected with those prejudices which the mere mention of South Kensington invariably awakens in the mother country. It has been the usual fate of the last-named undertaking from the very first that every scheme which promises to become useful is in due time dwarfed and crippled by some fresh enterprise more pretentious than the one preceding it, nothing being thoroughly completed because the necessary funds are diverted into some entirely new channel of expenditure. South Kensington, as we all know, was intended for the advancement of Science and Art. Some people deny that it has succeeded in advancing either; but we may safely assert that if it has rendered some service to Science its services to Art have been far greater; and, indeed, the complaint that Art has been promoted at the expense of Science is perhaps not altogether without some justification. At all events, Art at South Kensington has a great deal to show for the money spent on it, while Science has not.

In the term Art we, of course, include architecture; and how splendid has been its expenditure on those sacred acres,

Digitized by Google

the bricks and mortar are there to testify. They are not unworthy of the locality and the objects they are designed to further; but they have been erected without any general plan, or are appropriated for purposes which exclude in many cases the very objects which the Institution, as a whole, was intended to serve. A correspondent of *The Times* on Saturday last points out that the Royal College of Music about to be erected close to the Albert Hall will be ridiculous if it take any shape between a cloister and an eighteen-storied factory. Such is the consequence of having built without foresight a vast music hall to begin with, leaving the provision for teaching musical science to follow after. In the same paper is a report of the discussion in Parliament on the Civil Service Estimates relating to South Kensington, when a similar state of affairs was disclosed in connection with the Science Classes. In a speech at Newcastle a short time previously Lord RANDOLPH CHURCHILL is reported to have said that if the subjects of Science and Art were left to local effort their advancement would be secured without any aid from the Government. We do not agree with his Lordship in this, and it so happens that the local school he was referring to is an example of how local effort may be usefully supplemented by Government aid, without which, indeed, local effort probably would not have been evoked, and almost certainly would not have succeeded. But to the statement that in no other country of Europe is so little done as in England for Science and Art, his Lordship's rejoinder that we spend £500,000 a year on those objects is of considerable force, and he is not alone in thinking that we do not get what we are entitled to for so large an expenditure.

Sir H. ROSCOE is evidently, on this point, of Lord RANDOLPH'S opinion. The discussion arose on a vote to complete the sum of £9,000 for science and art buildings. Now, as we have already said, the most conspicuous—perhaps the only discoverable—examples of lavish expenditure on the non-official features of South Kensington are the buildings; yet, although fresh demands are continually made for their enlargement or beautification, the member for South Manchester roundly declared that "the accommodation at the only Government school in this country for teaching science teachers would be a disgrace to any third-rate German town." We do not attach much importance to comparisons of this sort; but going on to particulars nearer home the facts do seem to warrant the term disgraceful. He had, said Sir H. ROSCOE, that day visited the Science School at South Kensington, under the able control of Prof. RÜCKER. It occupied a temporary building, rented from the Commissioners, and was used as a laboratory. This building, utterly insufficient already, was about to be taken away from the Science School because the ground was required for the Imperial Institute! Here we have the old story over again, only this time in a reverse order, science being elbowed into a corner, and then thrust out of the back door to make room for a more popular or more influential tenant. One would have supposed that not only space but building accommodation was still plentiful enough at South Kensington; but according to Sir H. ROSCOE the students who now work in the laboratory would be thrown out of employment, and the school would have to reject a large number of applicants who wished to study there. The school, be it remembered, is not a gratuitous one, subsisting on the generosity of the State; the fees amount to £3,500 a year from the students alone; and if they are scattered, as we hope and trust, thanks to Sir H. ROSCOE'S interposition, they may not be, this large sum will go with them elsewhere. It has been a matter of some surprise that the City and Guilds Central Institute has lately taken in hand the training of science teachers, a function which the nation has a right to expect should be discharged by the South Kensington educational machinery. But after this explanation we can only congratulate ourselves that there is the City and Guilds Institute to fall back upon where the State institute has failed.

Mr. PLUNKET, representing the Office of Works in this matter, confessed its inability to deal with the existing congestion satisfactorily so long as the South Kensington authorities and the Treasury differ in their views as to what ought to be done. It will be news to most people that, according to Mr. PLUNKET, the Science and Art Department has "very clear and wide views" as to provision being made "not only for present needs, but for the future development of this great institution." On the other hand, the Treasury has equally clear but narrower views on this subject; and in the light of past experience nobody can seriously wonder at it. The clearness of the views at South Kensington has not been very apparent hitherto, whatever their breadth may have been. At present both characteristics are said to be concentrated on preserving "four large handsome residences at the eastern side of Exhibition-road" for the occupation of certain officers of the Department, the Treasury being equally fixed in its determination to utilise those handsome residences for temporarily relieving the congestion in the main buildings. We offer no opinion on this grave question of official residences. All other things being accommodated, it is obviously desirable that officers of educational establishments, including, of course, the professional staff, should live on the premises. But we are not told who the officers are; and it strikes us as odd that no better reason for their presence in "four large handsome residences" adjoining is put forward than that, in the event of the museum catching fire, their occupants would be able to indicate where the most precious of its treasures are stored. This, from an ex-Minister like Mr. MUNDELLA, and others who took the same line, rather discounts their professed anxiety to find adequate accommodation for science teaching, coupled with their protestations against extravagant expenditure. Lord RANDOLPH CHURCHILL has obtained promise of a return showing all the sums that have been spent on the South Kensington buildings. For our part, we should like to know the sum that has been spent on Science teaching. It would not amount to very much, we fear, if the receipts were set against the expenditure. But whatever it has cost, the duty of promoting technical education is one that the nation has made up its mind to perform, and we trust no effort will be spared to prevent the threatened scandal to which Sir H. ROSCOE drew the attention of Parliament last Friday evening.

ROYAL METEOROLOGICAL SOCIETY'S EXHIBITION.

BY WILLIAM MARRIOTT, F.R.MET.SOC.

(Continued from page 595.)

The exhibition contained numerous objects which had been damaged by lightning. The Royal College of Surgeons exhibited the clothes of a man which were torn off his body by lightning on June 8th, 1878, while standing under a tree near Ashford, Kent. These comprised a cotton jacket, flannel undervest, trousers, stockings, garters, boots, and watch. The man when struck was thrown some distance from the tree, while most of his clothes were torn completely off his body and hurled a considerable distance beyond. The man was not killed, but was rendered unconscious; he is still alive, but has a great horror of thunderstorms!

Two photographs were exhibited which further illustrated the effects of lightning on human beings. The first was of the shoes of some children who were struck in Atcham Church, Shrewsbury, in July, 1879. These were burst out in a similar

Digitized by Google

manner to those of the man already referred to. The second photograph was of the arm of a boy struck by lightning at Dunse, Berwickshire, on June 9th, 1883, showing the arborescent markings.

Mr. W. Leonarde exhibited specimens of telegraph and signalling apparatus used on the South-Eastern Railway which had been damaged in thunderstorms, and the Postal Telegraph Department showed portions of a telegraph line wire which was fused by lightning at Stornoway on May 1st, 1884.

Prof. D. Colladon sent a case of interesting specimens, showing the effects of lightning on trees, &c.; while other exhibitors showed portions of a rafter, pieces of wood and bark from various trees, &c., all of which had been struck by lightning. The destructive effects of lightning were also illustrated by numerous photographs.

Mr. Symons, at the meeting of the Society, read a paper "On the Non-Existence of Thunderbolts; elucidated by accounts of searches after them" (*see* page 545). The specimens of these so-called thunderbolts were included in the exhibition, and were of a very amusing nature. One was a cannon ball, which was found at the bottom of a hole in a manure heap, after a flash of lightning had struck near it. A second alleged thunderbolt, which was reported to have fallen in Westbourne Park, Notting Hill, on June 30th, 1866, was really a piece of coal; while a third, which was stated to have fallen at Kilburn on July 5th, 1877, was merely a clinker from a fire engine. The largest so-called thunderbolt exhibited was that which is reported to have fallen at Casterton, in Westmoreland, sometime between 1830 and 1840. This is said to have fallen under a large tree, killing a sheep, and penetrating the ground to a depth of about six feet, and when afterwards dug up was quite hot. In appearance it much resembled a volcanic bomb; it is, however, really a nodule of sandstone, but was doubtless found in the hole made by the lightning flash.

Closely allied to thunderbolts are fulgurites, which are formed by the lightning penetrating a bed of sand containing much silex, and fusing the sand into a kind of glass. Two drawings of fulgurites were exhibited, one being about 9ft. long. The actual fulgurite is in the British Museum, for which it was purchased in 1851.

A number of meteorites were also exhibited, one of which shows the Widmanstätten figures. Mr. W. Sowerby showed a piece of the meteoric iron found near the Great Fish River, Cape of Good Hope. This contains about 10 per cent. of nickel. Of a portion of this meteorite Mr. James Sowerby had a sword forged, and presented it to the Emperor of Russia in 1814.

A prominent feature of the exhibition was the valuable and interesting collection of photographs of flashes of lightning, which had been received in response to a circular issued by the Council of the Royal Meteorological Society in June last asking for such photographs. More than 50 photographs were exhibited, the specimens coming from all parts of the world. It is the practice of artists to represent lightning in their pictures as a series of zig-zags. True lightning, however, as shown by the photographs, does not take such a path, but passes along in an undulating and sometimes very erratic course. Side by side with these photographs were exhibited three diagrams of lightning made by Mr. James Nasmyth, F.R.S., in 1856, showing—1. Nature's lightning; 2. Painter's lightning; and 3. Forked lightning. The form of lightning as depicted by Mr. Nasmyth very closely resembles that pourtrayed in the photographs, and shows what a careful and accurate observer Mr. Nasmyth must have been. From an examination of the photographs it seems that the lightning flash does not always appear as a mere line of light. Several of the flashes have a ribbon-like appearance, and seem to be of a perceptible breadth, while in one of the photographs there is a *dark* flash. A large number of photographs of flashes of lightning were taken in London during the great thunderstorm on August 17 last. Mr. E. S. Shepherd, of Westbourne Grove, succeeded in obtaining eight photographs during this storm, one of which is reproduced in Fig. 7. Some of the photographs taken in the United States were of great beauty, especially those obtained by Mr. L. S. Clarke on the top of the Alleghany Mountains on August 2, 1887; one of these is reproduced in Fig. 8. The Royal Meteorological Society had enlargements made of five of the American photographs, and these showed up the flashes to great advantage.

Several new instruments were exhibited, including Dines's maximum wind pressure instrument, Rechnagel's electric anemometer, Tripe's arrangement of the rain-band spectroscope, Colladon's instrument for illustrating the formation of waterspouts, the Schanschieff electric lamp, Jordan's new pattern photographic sunshine recorder, &c.

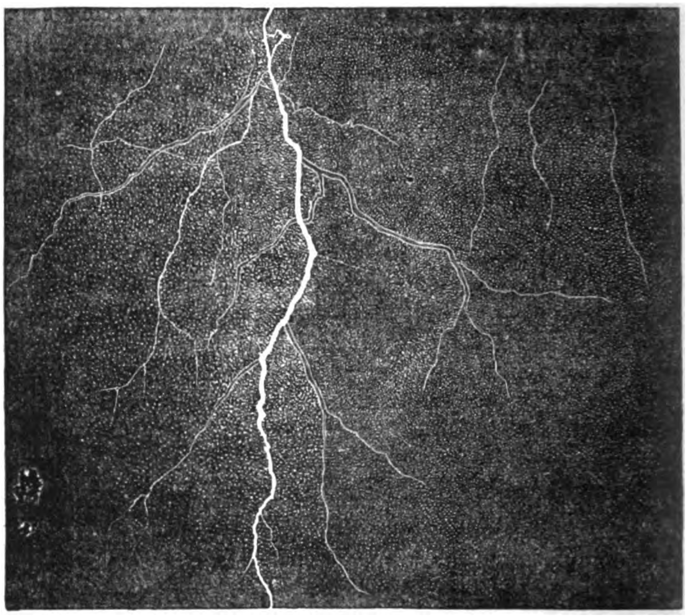

FIG 7.

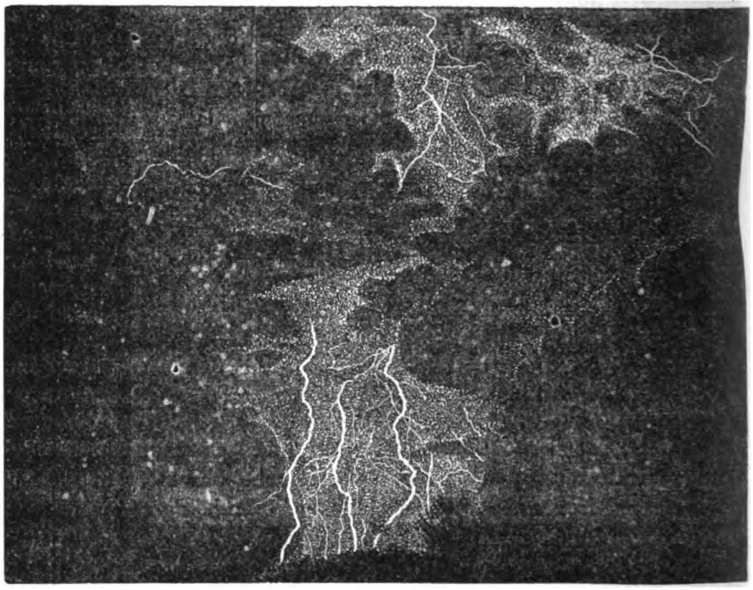

FIG 8.

Prof. Colladon's instrument for illustrating the formation of waterspouts is a very pretty arrangement, and attracted a considerable amount of notice. It consists of a large glass vessel, almost filled with water, and into which has been thrown some sawdust, which soon sinks to the bottom. On turning a handle a fan revolves in the water, and imparts to it a circular motion. Very soon the dust at the bottom begins to revolve, and is then drawn up in a column, and looks exactly like a waterspout.

The Schanschieff portable electric lamp is a very ingenious arrangement. The lamps are made in three patterns, viz., a four cell reversible and a three and four-cell round,

Digitized by Google

with dipping elements. The weight of the small pattern is about 6lb. The battery is a single fluid primary one, entirely self-contained. It is a very simple combination of carbon-zinc elements, charged by a special solution of a salt of mercury. When in action the mercury is deposited in the cells, and is thus not lost. The carbon plates do not require renewing, and will last an indefinite time, while the zincs only require to be renewed after about 60 hours' work. In the reversible pattern, when the light is required, it is only necessary to reverse the position of the lamp, by which motion the battery elements become immersed in the solution, and the lamp is brought to incandescence. Again reversing its position, the lamp is at once put out of action.

A large number of photographs of meteorological instruments, of clouds, &c., were also exhibited, as well as several photographic records of atmospheric electricity by Thomson's electrometer at the Greenwich and Kew Observatories. These showed the disturbance of the electrical condition of the atmosphere during the snowstorm on Dec. 26th-27th, 1886, and during the thunderstorms on May 22nd, 1886, and August 17th, 1887. Prof. H. Dufour also sent some photographic records from his electrometer at Lausanne, Switzerland. These showed the kind of electricity that was recorded during certain types of weather, *e.g.*, fine, cloudy, rain, snow, hail, thunderstorm, &c.

A striking photograph was that showing Krakatoa in eruption in May, 1883. This was reproduced from a photograph taken on board a steamer.

REVIEWS.

Proceedings of the Royal Society of Edinburgh, Session 1886-87. No. 124.

The contents of the present number of the *Proceedings* of the Royal Society of Edinburgh comprise the papers presented during the period from May 2nd to July 18th, 1887; from which it will be seen that the publications of this Society are not characterised by amazing promptitude. The electrical papers contained in the present number are not numerous, but they nevertheless comprise researches which should fill a permanent niche in the records of electrical science. We refer more especially to the two papers by Mr. W. Peddie, B.Sc., "On the Increase of Electrolytic Polarisation with Time," and "On Transition Resistance at the Surface of Platinum Electrodes, and the Action of Condensed Gaseous Films." The occurrence of a surface resistance between certain electrodes and the solution was first enunciated by Dr. Gore in a paper read before the Birmingham Philosophical Society. But inasmuch as the phenomena is with difficulty discriminated from that of counter E.M.F., it has not hitherto met with universal recognition. Attempts have been made to settle the question by ascertaining whether the heat effect (C^2R) is proportionately greater at the surface of the plate, but the experiments have not proved satisfactory.

Mr. Peddie's research, however, offers evidence of a very conclusive character, and not only proves the reality of transition resistance, but shows also that it is due to the occlusion of a gaseous film upon the surface of the electrode. The experiments were made by taking a series of observations of the current strength of one Daniell cell through a pair of platinum electrodes immersed in dilute sulphuric acid. The E.M.F. was, of course, insufficient to effect decomposition. In the first case the electrodes were allowed to remain in the acid for several hours before the experiments were made. Since only one Daniell cell was used the liquid was not decomposed, and the current strength after two or three seconds was only of the order of thousandths or ten-thousandths of an ampere, and continued to fall. A curve was then plotted of the values of the current at certain intervals. The plates were afterwards taken out, heated to redness, replaced, and a second series of observations was made. It was then found that the current was now very much larger than before, but that by the insertion of resistance in the circuit the original curve could be almost exactly reproduced. The specific resistance of the gas film might perhaps be obtained in this way if we could estimate the thickness of the film with sufficient accuracy. Mr. Peddie concludes only that "the order of the specific resistance is the same as that of ordinary dielectrics."

Mr. Albert Campbell, B.A., has an important paper "On the Direct Measurement of the Peltier Effect." Hitherto it has been a pure assumption that the Peltier effect vanishes at the neutral point. The chief object of Mr. Campbell's experiments was to obtain direct evidence as to the truth of that assumption. The experimental investigation of this subject is by no means an easy task, owing chiefly to the difficulty of measuring and maintaining constant the high temperatures required.

The results, however, were of a very fairly concordant character, and serve to justify the theory as already understood. The following extract may serve to convey a useful hint for other experiments in which time readings are required:—

"In order to investigate the rate at which the growing Peltier effect temperature-difference showed itself by the thermopile deflection, the following simple chronographic method was adopted. In this a number of observers were made use of. Observer A held a watch to his ear, and counted half-seconds aloud in exact time with its beats, also making and breaking the battery circuit at exactly the proper times. Observer B, watching the galvanometer scale, said sharply the syllables, 'Tic, tac, to, tee, tic, tac, to, tee,' and so on, as the light-spot passed over certain prearranged divisions of the scale. Eight other observers noted down the numbers after which they heard the tic, tac, to, or tee, one of those words being allotted to each pair of observers. This method proved wonderfully accurate. The pairs of observers very seldom disagreed by half a second, although the numbers had to be noted very rapidly."

Fortschritte der Electrotechnik. By Drs. Karl Strecker, Dobrowolski, Kiliani, and Pirani. (Berlin: Julius Springer, 3 Monbijouplatz.)

The present number of this quarterly catalogues the current electrical literature of the third quarter of last year. It will be found well up to the mark of the first two parts, which we noticed in December last. It contains some 1,200 headings, each with several references to various journals.

THE SIZE OF INCANDESCENT LAMP FILAMENTS.

Commenting on the fact that the efficiency of incandescent lamps with stout filaments is greater than those with fine, M. Hospitalier points out in *L'Electricien* that several different causes combine to render this the case. If, for example, we take the case of two lamps, each absorbing 64 watts, but let one have a fine filament having a resistance of 64 ohms, whilst that belonging to the other is one-fourth the length and four times the diameter, thus having a resistance of one ohm only, then the volume of the second will have consequently a greater calorific capacity, so that the effects of any accidental variations in the strength of the current will be greatly diminished. Moreover, the section of the second filament will be 16 times that of the first, whilst the current passing through will be only eight times as great; hence the current density will be only one-half of what it is in the fine filament. Adding to this the fact that it is easier to secure uniformity in the manufacture of stout filaments than of fine, there appears ample ground theoretically for the longer life of stout filaments, which practical experience shows.

Writing on the same subject in *La Lumière Electrique*, M. Henrique gives the following formulæ for filaments of cylindrical section, and for lamps of the same voltage:—

"If a lamp of n candle-power has a filament of length l_n, and diameter D_n, then the length and diameter of a filament of the same make to give m candles at the same efficiency, must satisfy the equations

$$\frac{l_m}{D^2_m} = \frac{n}{m} \frac{l_n}{D_n^2} \qquad (1)$$

Digitized by Google

and $$l_m D_m = \frac{m}{n} l_n D_n \quad . \quad . \quad . \quad . \quad . \quad (2)$$

"Equation (1) follows from the consideration that for the same efficiency the resistance of the filaments must be inversely as their candle-power. Equation (2) follows from the fact that for the same efficiency the surface temperatures must be the same, and therefore the radiating surface (neglecting the influence of the attachments) must vary directly as the candle-power. Resolving these simultaneous equations we get

$$\frac{Dm}{Dn} = \sqrt[3]{\frac{m^2}{n^2}}, \text{ and } \frac{l\,m}{l\,n} = \sqrt[3]{\frac{m}{n}}.$$

"According to this formula, in order that two lamps of the same type may have the same efficiency while one has twice the candle-power of the other, the lengths of the filaments must be as $1 : \sqrt[3]{2}$, or as 1 : 1·26, and the diameter as $1 : \sqrt[3]{4}$, or as 1 : 1·59 (nearly)."

THE OUTPUT OF DYNAMOS PER UNIT WEIGHT OF COPPER.

Accurate comparisons between the performances of different dynamos are well known to be very difficult to put in such a form as to be any real index of the relative values of such machines. If, for instance, we tabulate the relative output per unit weight of copper, this tells us very little in the absence of information as to the peripheral speed of the armature current density allowed (or, still better the temperature of the coils after running for some time at full load). However, we give the following table, which has been compiled by M. W. Peukert *(Zeitschrift für Electrotechnik)*, for what it may be worth :—

	Machine.	Revolutions per minute.	Diff'r'nce of potential in volts.	Output in watts.	Total weight of copper in kgs.	Gms. of copper per watt.
1	Crompton	400	600	72·000	637·1	8·85
2	Crompton	700	110	54·000	473·7	8·77
3	Ganz and Co. (VP_5)	670	105	50·400	240 0	4·76
4	Goolden-Trotter	765	56	16·000	104·6	6·54
5	Goolden-Trotter	1,070	77	22·400	104·7	4·67
6	Brush	400	80	300·000	3000·0	10·0
7	Ganz and Co. (machines with 6 poles)	1,000	1,500	52·500	82·0	1·56
8	Crompton (type No. 30)	440	110	25·500	395·0	15·5
9	Mather and Platt	1,000	100	22 000	144·0	6·4
10	Lahmeyer, G. (III.)	1,250	65	3·900	50·3	12·89
11	H. Pöge	840	65	6·500	58·3	8·96
12	Bollmann	750	100	100·000	556·0	5·5
13	J. Einstein and Co.	1,100	100	4·500	35 0	7·7
14	Edison-Hopkinson	800	100	33·000	118·0	3·57
15	C. E. L. Brown	1,000	65	10·400	45·0	4·32
16	C. E. L. Brown	1,000	55	6·600	21·6	3·3
17	Brush	1,000	100	380 000	2833·0	7 45
18	Elwell-Parker	1,000	110	50·600	454 0	9·1
19	E. Fein (machine with interior poles)	520	110	15·000	88·4	5·88

The extraordinary differences between the performances of the various machines is in some cases difficult to account for, even when reasonable allowance is made for the known and unknown conditions. For instance, it would be interesting to know how it happens that in the two machines, Nos. 1 and 8, by the same makers, so great a difference exists. Both are slow-speed machines, but one runs 40 revolutions faster than the other, and yet the slower machine has a greater output per unit weight of copper in the ratio of 15·5 to 8·85. The performance of the high-tension machine of Messrs. Ganz and Co., which yields a watt for every 1·56 gramme of copper, is, if correct, something which that firm may justly be proud of.

Dr. Kohlrauch.—The *Centralblatt für Electrotechnische* states that Dr. F. Kohlrauch has accepted the Chair of Physics at the University of Strassburg and Ostern. The appointment has caused the greatest satisfaction among the leading scientists of Bavaria.

CENTRAL STATION LIGHTING.—TRANSFORMERS v. ACCUMULATORS.*

BY R. E. CROMPTON.

The present Paper is the outcome of the discussion which took place on Messrs. Kapp's and Mackenzie's Papers on tranformers, recently read before this Society. I was asked to give facts and figures in support of the statement I then made, that I believed the distribution of electricity by transformers offered no special advantages over other methods, particularly over distribution by means of accumulators used as transformers.

However, after compiling the statement of facts and figures necessary for my purpose, I found that I had undertaken a task of a much heavier nature than I originally intended ; and I must apologise for the present Paper having a much wider scope than its title would warrant.

In fact, I find it necessary to commence by discussing some of the conditions of the supply of electricity from electric stations which are common to all systems of distribution, and about which little or nothing has hitherto been written or said. In England central station lighting has been such an affair of yesterday that it is hardly to be wondered that what little knowledge exists on the subject should be confined to the few who have lighting stations under their immediate charge ; and when we look to the Continent, or to America, to supplement this meagre stock of knowledge, we find the conditions of demand for light differ from those of a large English town, such as London, so that they do not much help us in our investigation. However, during the past few years I have done my best to make myself acquainted with the main facts which appear likely to govern the future commercial success of such undertakings.

I must at once divide the schemes for electric supply into two classes :—1st, those confessedly carried out in a temporary manner, and for the purpose of popularising the electric light, and inspiring the confidence of the public in supply companies as a form of investment ; and 2ndly, those intended to be of as permanent a nature as the gas supply, with which they come into competition. I think to the first class we must relegate such systems of supply as those at Brighton, Eastbourne, the present supply from the Grosvenor Gallery, in fact all those which distribute by means of overhead wires, picking their customers here and there, and which, although they have served a very useful turn in familiarising the public with the use of the electric light, cannot be considered as in any sense fitted to develop themselves into a complete system of supply when the time arrives that more than half the houses may be expected to take the light.

In order to get an adequate idea of the nature of the demand, or what I call the load diagram of a system of supply, we cannot do better than refer to the diagrams of a similar nature taken by the gas companies. Having recently had the advantage of carrying out electric supply stations for several gas companies, I have had access to such load diagrams for gas lighting, and from these and from the experience already obtained of electric supply in London, I have constructed a load diagram which I believe will be found a fairly representative one for an ordinary London residential district, consisting partly of private houses, partly of shops, with the usual sprinkling of hotels and public buildings. No doubt a district containing a very large number of theatres would have a somewhat different diagram, but not differing so much as to materially affect the arguments that I am about to found on these load diagrams. Through the kindness of Dr. Fleming, I am able to lay before you several load diagrams obtained from lighting stations in America, which you see coincide very fairly with the one I have prepared for London. We learn from these load diagrams—1st, that the average daily outputs in units throughout the year is about three and a-half times the maximum load in kilowatts ; in other words, that a station having a plant equal to the supply of 600 kilowatts—that is to say, 10,000 lamps, of 16 candle-power, each simultaneously alight—could only calculate on selling an average quantity of 2,100 units per day. This fact, which has such an important bearing on the possible profits to be obtained from a station of a given size, appears to have been completely ignored by the writer of an article on central stations in *Industries* dated the 2nd December, 1887, who estimates that a plant of this size would be able to supply daily 3,600 Board of Trade units, which is 73 per cent. in excess of the figure I have given above. The next point we have to note, common to all systems of distribution, is the extent of underground mains necessary to distribute a given supply of electricity, and the probable cost of such mains when laid underneath the footways of our streets. Starting once more on the above-quoted 10,000-light plant basis, I find, from careful note of the transformed to currents of low E.M.F., suitable to the glow and arc lamps used by the consumers, and which I hereafter call the

* Paper read before the Society of Telegraph-Engineers and Electricians yesterday, Thursday, April 12th, 1888.

TABLE No. 2.

COST OF LAYING 100 YARDS OF DOUBLE CONDUCTOR OF BARE COPPER CARRIED ON INSULATORS IN A CULVERT.

Area in square inches	0·25	0·5	1·0	2·0	2·55	3·00
Area in square millimetres	161·25	322·5	645	1290	1645	1935
Weight of copper in lbs. per 100 yards	576	1153	2306	4612	6125	6918
Cost of copper at 7¾d. per lb.	£18 15 0	£37 5 0	£74 10 0	£149 0 0	£190 0 0	£224 0 0
Laying	9 0 0	9 12 0	9 12 0	9 15 0	9 15 0	10 0 0
Insulators	0 4 6	0 4 6	0 4 6	0 4 6	0 4 6	0 4 6
Six surface boxes and connections	10 0 0	10 0 0	10 0 0	10 0 0	10 0 0	10 0 0
Culvert, 18 inches × 12 inches, for 2 lines conductor, in brickwork and cement, replacing pavement	53 8 0	53 8 0	53 8 0	53 8 0	53 8 0	53 8 0
Engineers and superintendence	6 0 0	10 0 0	10 0 0	10 0 0	10 0 0	15 0 0
Total	£97 7 6	£120 9 6	£157 14 0	£232 7 6	£263 7 6	£312 12 6
Extra for copper at 9½d. per lb.	3 5 0	8 10 0	17 0 0	34 0 0	43 10 0	51 0 0
Total	£100 12 6	£128 19 6	£174 14 6	£266 7 6	£306 7 6	£363 12 6
Cost of copper per lb. laid complete	42d.	27d.	18·2d.	13·8d.	12d.	12·6d.
Current in amperes	90	180	360	720	910	1,080
Cost per ampere	1 2 3	0 14 5	0 9 8	0 7 5	0 6 9	0 6 8½

amount of electricity used by various classes of houses, that in order to sell an average of 2,100 units per day our distributing mains must reach not less than 1,000 houses. We may take the average width of the London house at 10 yards; to this we must add 50 per cent., on the supposition that only two houses out of three will take the light for some time to come; and on to this we must again add 30 per cent. for such proportions of the roads, such as crossings, dead walls, &c., traversed by the mains which do not front houses taking the light. We thus find that every house requires 20 yards of distributing main; or to distribute the daily average supply of 2,100 units, 20,000 yards of main. In addition to these distributing mains we must contemplate the probability of the generating station being placed at a distance of 2,000 yards from the centre of the district supplied, so that in all we have to provide 22,000 yards of mains of the two classes of mains. For convenience of nomenclature I call those mains which form the primary wire to the transformers, or carry the charging current to the accumulators, "charging mains;" and those from the transformers to the houses, or from the accumulators to the houses, "distributing mains." Next, as to the cost of these mains. I have prepared two tables, which show how wide of the mark is the popular idea that the cost of the mains is greatly influenced by the cost of the copper conductors themselves. I have stated at this Institution that much nonsense has been talked on the subject of the cost of copper; by this I did not intend to be disrespectful to any particular speaker, but to point out in strong language that the habit of basing estimates of distribution on the cost of copper (with but a small percentage added for insulation and laying) was one to be avoided, as it has led to erroneous conclusions, on which have been based arguments far too favourable to systems using currents of high E.M.F.

No doubt this habit of considering the cost of copper as such an important element in the calculation has arisen from the fact that, although this question of electrical distribution has been for years under discussion, and has had volumes written about it, yet our experience in laying and repairing such conductors has been until quite recently almost *nil*. The tables now before you are based on the little experience that I have gained during the last three years, and I trust they may be of some service to the Members of the Institution. Many of the figures are the actual prices paid out on executed contracts, and the other ones are calculated from them; so that it is quite certain that the figures quoted in the table are not far wide of the mark. You will notice that, apart from the price of the copper itself, the additions we have had to make for the insulation troughing, cost of laying, providing and fixing surface boxes, digging and guarding the trenches, taking up and replacing the flagging and wood pavements, are almost a constant quantity depending only on the length of the roadway that is disturbed, and, consequently, when considered in relation to the cost of copper itself, are at a maximum when the section of the copper is small and decrease rapidly as the section augments.

Table No. 1 is for laying copper in the form of insulated cables in the old and well-tried way. Table No. 2 is for a form of main which I have successfully adopted during the past year, and which consists of a bare copper conductor, supported and insulated in concrete subways or culverts by porcelain insulators. I am not at present submitting the latter system for your criticism. In some respects it is not yet perfect; but I mention it as I am employing it to a considerable extent myself, and believe that it will prove a very valuable form of conductor for whatever system of distribution is used. The completed main consists of such very durable materials, and the facilities for repairs and renewals, or for increase in the section of the conductor, are so great, that the annual charge for the upkeep and depreciation of these mains is not likely to exceed 25 per cent. of that of the older form of cables insulated with the continuous covering, whatever material may be employed for that covering.

With these considerations of the load diagrams, the extent of distributing system, and the cost of the mains before us, we can now proceed to compare the merits of distributing the electricity by two systems—the first being by alternating currents of high E.M.F.,

Digitized by Google

A.T. system; and second, the supply by means of direct currents of medium E.M.F. used to charge accumulators arranged in series, the current being taken off the accumulators at the lower E.M.F. required for the lamps, and which I hereafter call the B.T. system.

All modern systems of distribution aim at the reduction of the first cost of the distributing plant—that is, of the charging and distributing mains, and all appliances belonging to them, such as transformers, regulating devices, street service boxes, house connections, &c., providing that such reductions shall not be at the expense of the efficiency of the system. It is difficult to fix an exact percentage of the loss allowable in the distributing plant, as so much depends on the length of the working hours, but I take it for granted that in no case must this loss exceed 10 per cent. I further take it for granted that the extreme variation allowable in the E.M.F. in the distributing mains must not exceed 4 per cent. So much has recently been written on the A.T. system that I will not lengthen this paper by describing it further than by stating that for purposes of my comparison I take the system as generally described by Mr. Kapp in his paper on transformers; or by Mr. Mackenzie, in his paper on transformers; and in an article in *Industries*, dated December 2nd, 1887, for which I believe Mr. Kapp is responsible, which gives very complete data on the first cost of an installation for 10,000 60-watt lamps, burnt simultaneously. On the other hand it is necessary for me here to briefly explain the B.T. system, which I propose to compare with it.

At Vienna the arrangements proposed by Mr. Monnier, and successfully carried out by myself and others, consist of charging from a central station groups of batteries of accumulators arranged in series. Each group of accumulators consists of 52 cells, giving the 100 volts required for the lamps, with a comfortable margin. The total E.M.F. required to charge the four groups of batteries in series varies from 430 volts, at the time the batteries are giving off work, to 480 volts, for the short time during which the charge is being completed. This includes the loss in the mains, generating stations being situated 1,400 yards from the distributing station. During five hours of lighting about two-thirds of the current comes direct from the dynamos; but during this time for short periods the demand of current often increases to such an extent that these proportions may be reversed, and the batteries supply two-thirds of the total. As this system has now been in use for upwards of nine months without any hitch or trouble whatever in connection with the electrical work, we may consider it proved there is no danger or difficulty in using currents of such high E.M.F. as 480 volts connected permanently to the distributing mains. The system may of course, be united with three or two groups only in series. An example of the last is the Central Station belonging to the Lemans Gas Company.

I now propose to commence my comparison of the two systems from four points of view:—

1st.—As to trustworthiness, steadiness, and quality of the lighting.

2nd.—As to the first cost of the plant, and

3rd.—As to working cost and maintenance.

4th.—As to the probable output, and hence maximum income, that can be safely obtained from the sale of electricity in each case.

I think it will be allowed that the commercial success of an electric light undertaking depends on these four points. I do not propose to dwell much on the first point. It is generally admitted that a system which uses storage must be superior to a system in which the continuity of the lighting depends entirely in moving machinery. There are many reasons why I should not make invidious comparisons on these points between existing systems. No one is prepared to dispute the fact that the A.T. systems hitherto installed have been remarkable for frequent interruptions in the lighting, whereas the reverse has been the case with the B.T. system. It remains for us to consider whether the undoubted great advantages which the B.T. system possesses in this respect is not purchased too dearly; and this matter will occupy the remainder of my Paper. The comparison I now make is for a system of electrical supply for London for 10,000 60-watt lamps, or their equivalent, simultaneously alight at hours of maximum demand,

1st. By alternating currents reduced from 2,000 volts to 60 volts by transformers.

2nd. By direct currents reduced from 440 volts to 110 volts by accumulators used as transformers.

Cost of Generating Station.—For the A.T. system I adopt the figures given by the writer in *Industries* on page 600 of the 2nd December, 1887. He therein proposes to provide for the 10,000-lamp plant dynamo power, including reserve equal to 865 kilowatts, and he fixes the price of those as £5,540. As regards motive power, I do not propose to take advantage of the writer's far too liberal estimate of its cost at £12 per indicated horse-power, but take it at the lower figure of £8. 12s. per indicated horse-power, thus reducing the cost to £12,500. I have estimated the cost of the building, chimney stack, water tanks, connections for water, drains, all measuring instruments and other accessories, at £11,000, thus bringing the total cost of the generating station of the A.T. system to £29,040. For the B.T. system I propose to provide plant of exactly similar type to that I have already supplied to Vienna. As I have said before, I propose that the dynamos should supply two-thirds of the maximum net output of 600 kilowatts. We therefore require about 448 kilowatts at the terminals of the accumulators; or, adding an 8¼ per cent. loss in the charging mains, 490 kilowatts in the generating station; 20 per cent. of reserve power will bring this up to 600 kilowatts, equal to 1,000 indicated horse-power. Such a plant may be conveniently divided into six sets of combined engines and dynamos, each of 100 kilowatts. Adopting the figure given above, viz., £8. 12s. per indicated horse-power, as the cost of the motive power, and that given by the writer in *Industries* at £8 per kilowatt, or £4,800 for the six sets of dynamos, and estimating that the cost of the building and other accessories, as before detailed, for the A.T. system will, in this case, be only £8,000, we find that £21,500 is the cost of the generating station for the B.T. system.

The cost of the alternating transformers is a very difficult matter to arrive at. The Grosvenor Gallery Company, I believe, with few exceptions, supplies every consumer with his own transformer; but Mr. Kapp, in his recent Paper, proposes to lay down a network of mains of much the same character as I use for the B.T. system, and to supply this network by a certain number of larger transformers, placed at frequent intervals in the network. It is difficult to see how any saving can be made by this arrangement. It will be noticed that, although it reduces the number of transformers, it introduces a new element of expense and difficulty, and that is, the providing of places to fix these large transformers. It may be that such places can easily be found, but my experience has been otherwise. It is not easy to find a place for any piece of machinery of a size between that which can conveniently be got into a surface box placed in the pavement not exceeding 1ft. in depth by 2ft. square, and a sub-station of the size I require for my battery transformers. In most cases there is no space either under the footways or under the street itself to form a water-tight chamber of sufficient cubic capacity for the purpose. Another difficulty and cause of additional expense which I think would tend to couterbalance any saving from the decreased number of transformers would be that the charging mains laid *to* the transformers, and the distributing mains *away* from the transformers, would have to be laid in the same trench or culvert, and this would be no small source of danger to those at work connecting houses on to the distributing mains. As I have not been able to obtain any reliable data on this modified system of Mr. Kapp's, I am obliged for the present to return to the system using one transformer for every two houses, and I think, for the reasons I have given above, the advocates of the A.T. system will not be able to make any great saving by adopting Mr. Kapp's suggestions.

TABLE 3.

COST OF 10,000-LIGHT OR 600-KILOWATT PLANT.

A.T.—Alternating Transformer Distribution.	£	B.T.—Accumulator Transformer Distribution.	£
Generating Station, Buildings, Chimney Shaft, Water Tanks, and General Fittings	11,000	Generating Station, Buildings, Chimney Stack, Water Tanks, and General Fittings	8,000
Dynamos and Exciters—865 Kilowatts, including spare sets, divided as convenient	5,540	Dynamos—600 Kilowatts, in 6 sets of 100 Kilowatts each	4,800
Motive Power, *i.e.*, Engines, Boilers, Steam and Feed Connections, Belts, &c, at £8. 12s. per I.H.-P. ..	12,470	Motive Power, *i.e.*, Engines, Boilers, Steam and Feed Connections, &c., at £8. 12s. per I.H.-P.	8,600
500 Transformers, *i.e.*, one to every pair of houses, at £15 each	7,500	4 Groups of Accumulators, in all 240 cells, in series, at £40 per cell, including Stands	9,600
2,000 yards Primary or Charging Main, exterior to area of supply, at £308 per 100 yards	6,160	2,000 yards Charging Main, at £306. 17s. 6d. per 100 yards (*see* Table 2)	6,137
20,000 yards Distributing Main, 50 mm. sectional area, at £91. 7s. (*see* Table 1)	14,270	20,000 yards Distributing Main, 161·25 mm. sectional area, at £100 12s. 6d. (*see* Table 2)	20,125
Regulating Gear	500	Regulating Gear	2,500
	£57,440		£59,762

Accumulators to be used as transformers must be of sufficient capacity to supply 200 kilowatts per hour for the hours during which the demand exceeds the 400 kilowatts supplied by the dynamos. The load curves shown in the diagram,* hanging before you, show that this period of maximum supply varies from about two hours in summer to four hours in winter. If I provide four

* We hope to give the diagram in our next issue.

Digitized by Google

groups of accumulators, each of which has a total capacity of 259 kilowatts, or 1,000 kilowatts for the four, I provide for five hours of extreme demand, which is a condition of things extremely unlikely to occur, even in times of a fog. For it must be noted that the demand for light during a fog in the daytime (in a district partly residential and partly supplying shops) is of a far lighter nature than the demand from the same district during the ordinary hours of maximum lighting; the reason being that, during the hours of maximum lighting, not only the lamps in the basement, passages, and a certain portion of the dwelling rooms require to be simultaneously alight, but all upstair passages and a certain proportion of the bed rooms also require light. This is not the case during a fog; only the basement, lower passages, and living rooms take the light, and these to not nearly the same extent as they do in the evening. In order to meet a case of possible interruptions to the charging current, which might take place at the time of maximum demand, we require these accumulators to be capable of being discharged without damage to themselves, and at a fair rate of efficiency, at a rate not less than 650 kilowatts. It is this latter requirement that has so long delayed the introduction of accumulators as transformers. Up to a recent date far too much attention has been paid to the capacity, and too little to the rate of possible maximum discharge. This state of things has lately been remedied, and I am told there are several makers of accumulators who can supply them to fulfil the above-mentioned conditions, and at the reasonable priced named by me in my estimate. It must be remembered that such accidental stoppages of the lighting current as are likely to take place would not probably last for more than a few minutes, that is to say, if due provision has been made for spare machinery, and if the arrangements for working the machines parallel and interchangeable have been properly carried out. Time will not permit me in the course of this Paper to describe fully the switch-board and regulating arrangements necessary for the B.T. system. These require to be so arranged that the loss due to the difference of E.M.F. between the charge and discharge of the batteries may be as small as possible. It is quite possible to work the batteries parallel to the charging current during the hours of maximum demand with little or no loss from this cause, the loss being confined to the hours when the batteries are being finally filled up before the engines are stopped. The sub-stations, which contain the accumulator transformers, can in almost every case be placed on "mews" property, and I have ascertained from accurate inquiry that there is no difficulty in obtaining accommodation for them in such property, with but few exceptions, within 300 yards radius of the houses to be supplied. In each case the sub-station consists of a battery room and living room for the man in charge. The plant in each sub-station consists of the batteries themselves, the regulating appliances above-mentioned, voltmeters and district meters as may be thought necessary.

Distribution.—In the case of the A.T. system the charging mains, as far as they lie within the area of supply, are in reality the distributing mains; in other words, we require 20,000 yards of distributing mains to reach the houses. I am informed that the section usually employed for the distributing mains of these 2,000-volt circuits, when the transformers are placed in parallel, is 50 millimetres cross section, or 19 strand, No. 15 B.W.G. From Table No. 1 you will see that this costs £71. 7s. per 100 yards. I have not worked out the cost of so small a section laid on my own plan in the culverts, but it would certainly not be less than £96 per 100 yards. However, adopting the lower figure, the distributing main will cost £14,270. The writer in *Industries* says that 720 kilowatts will have to be generated at the generating station for transmission to the area of supply; dividing this by 2,000 volts, we get 360 amperes as the current in the charging main. Adopting Prof. Forbes' tables for calculating the section of the conductor, we find that it ought to be about 645 millimetres, and if laid in the cable form, as in Table 1, but without surface boxes, would cost about £308 per 100 yards, or in all £6,160. It will be asked why I do not give to these charging mains the advantage of the somewhat lower cost of laying them as bare copper, as in Table 2, but I do not think it would be safe to leave conductors carrying currents at 2,000 volts thus unprotected in the culverts, as the risk to workmen employed on the district system would be too great, to which must be added the great risk to the consumers, of making an accidental contact from the charging to the distributing mains. I should here remark, that the very confident tone adopted by many supporters of the A.T. system rests on very slender foundations; they appear to forget that the great success obtained in America has been with overhead wires used as the primary or charging mains. We all know what a high degree of insulation is possible with overhead wires; we also know that extreme difficulty has been met with in America in all attempts to obtain sufficient insulation for wires carrying currents of high E.M.F. when laid underground. As a matter of fact, failure has been the rule, and success the exception. I believe that the difficulties of the A.T. system will commence when the contractors have to guarantee a perfect insulation with underground cables carrying currents at an E.M.F. of 2,000 volts. Let those who think otherwise read Prof. Elihu Thomson's remarks at the recent electric light convention in America. He used the following words :—"Distribution of current to groups of incandescent lamps, arc light, or other high potential lines should always be undertaken with great care, and it is thought that such work should only be undertaken when exceptionally favourable conditions for avoiding accidental leakages exist, especially should the potential of the line at the dynamo exceed 1,500 volts, or an amount which would sustain 30 arc lamps in series. One of the important elements of safety in such installations is simplicity and ease of inspection of the wiring, and no concealed wires should be used in them." Again, he says, "for house to house and general incandescent lighting, where the distances from the station are not too great, the direct low-potential systems possess most of the advantages, the difficulties of leakage from the defective insulation being of course at a minimum; but where the distances are so great as to make the required outlay for copper in the conductors practically prohibit the extension of the system, a transformer or converter system, if of good design and economy, may be made to yield excellent results." Now, the writer of these words is one of the greatest authorities on electric lighting matters in America, and a strong supporter of the A.T. system. I think, therefore, that I have not dwelt too strongly on the grave difficulties likely to be encountered by those who so glibly talk of laying underground charging mains, carrying currents at 2,000 volts potential, and I think that in all probability the additional precautions that will have to be taken to avoid failure of the insulation will be so expensive as to bring the total cost of the 22,000 yards up to practically the same sum as is required for the 2,000 yards of charging main, and 20,000 yards of distributing mains of the B.T. system, for which no special precautions are necessary.

I work out the cost of the latter as follows :—I use throughout bare copper mains of ·25 inch section for the distributing mains; that is to say, for the 20,000 yards at the rate given in Table 2 of £100 12s. 6d. per 100 yards, they will cost £20,125. The charging main will have to carry 910 amperes, and the extreme loss allowable being 8·25 per cent., its resistance must be 0·04 ohms. The double conductor will weigh about 45 tons: this can be laid as in Table 2, in brickwork, in cement culvert, at the rate of £306. 17s. 6d. per 100 yards, or £6,137. 10s. I have put down an item of £500 for the regulating gear for the A.T. system, and another one of £2,500 for the regulating gear for the B.T. system. The totals thus arrived at, and which you see before you on the wall, are £57,440 as the total cost of the A.T. system, and £59,762 for the B.T. system. These figures appear high, but I cannot see how they can be reduced, unless under very exceptional circumstances. In both cases a very large portion of the cost lies in the distributing plant, and of this, as you will gather from my Tables 1 and 2, the copper plays but an insignificant part, the real heavy charges being those inseparably connected with underground cables, viz., the cost of insulation and those connected with disturbing and replacing the surface of the streets.

(To be continued.)

THE RADIOGRAPH.*

BY M. LOUIS OLIVER.

The method suggested by the author some three years ago of timing the exposure of photographic plates by means of the radiometer has been much used by photographers both in France and in other countries. Of course, for the so-called instantaneous process the method is not required, but for slower exposures it is very useful. With the same objective, the same stop, and the same plates, a period of exposure determined by counting the same number of revolutions of the radiometer always gives the same results. Contrary to what might, perhaps, have been supposed, the accuracy of the method is not at all affected by the variation in the composition of the light at different hours of the day.

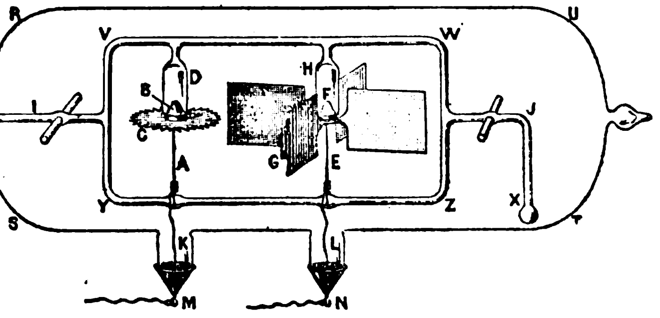
Thinking that it would be of interest to render this regulation automatic, I have been led to devise the apparatus described below, which I propose to call the Radiograph. Its function is to produce an automatic record of the total amount of light which falls upon its vanes, the record having reference *both to duration and to intensity.* The apparatus consists essentially of a radiometer which at every rotation closes an

* Abstracted from the *Comptes Rendus*, March 19th, 1888.

Digitized by Google

electric circuit, and through the medium of a relay moves a needle step by step upon a dial.

The mode of action is easily understood. At every rotation of the vane the projection G makes contact with the aluminium wheel and closes a circuit through K and L. A wheel is used for the contact solely in order to avoid checking the rotation of the vane. The current passing through this circuit is very small and is only used to close a relay contact, bringing into action a more powerful battery, by means of which a needle is caused to traverse a dial step by step, the position of the needle always corresponding to the numbers of revolutions of the radiometer. For photographic purposes it is easy to arrange a third circuit by which the shutter is closed when the needle arrives at any predetermined position.



R S T U is an envelope of glass in which a high vacuum exists.
A vertical steel needle supporting the cap B.
C light aluminium toothed wheel.
E vertical steel needle supporting the cap F upon which the radiometer vanes are mounted.
G projection on vane which turns wheel C.
V Y Z W supporting frame made of glass.
D and H glass tubes to keep caps A and B in position.
I J X are also portions of the glass framework.
K and L electrodes fixed to the needle A and E, and making contact through the mercury cups with wires M and N.

It is anticipated that the apparatus will sometimes prove of value for investigations in the various physical and chemical problems.

RULES AND REGULATIONS FOR THE PREVENTION OF FIRE RISKS ARISING FROM ELECTRIC LIGHTING.

ISSUED BY THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

Revised and Remodelled from the Rules issued by the Society in 1883, and from other sources of information, both home and foreign, and recommended by the Council in accordance with the Report of the Committee appointed by them to consider the subject.

Members of the Committee:—Prof. W. G. Adams, F.R.S., past president; Prof. W. E. Ayrton, F.R.S., vice-president; Sir Charles T. Bright, past president; E. B. Bright; R. E. Crompton; W. Crookes, F.R.S., vice-president; Dr. J. A. Fleming, M.A.; Prof. G. Forbes, F.R.SS. (L. and E); Prof. G. C. Foster, F.R.S., past president; Edward Graves, president; J. E H. Gordon, B.A.; Dr. J. Hopkinson, F.R.S., vice-president; Prof. D. E. Hughes, F.R.S., past president; W. H. Massey; W. H. Preece, F.R.S., past president; Sir David Salomons, Bart., M.A.; Alexander Siemens, vice-president; C. E. Spagnoletti, past president; James N. Shoolbred, B.A.; Augustus Stroh; Sir William Thomson, F.R.SS. (L. and E.), past president; Major-General C. E. Webber, C.B., (Ret) R.E., past president.

These general rules are drawn up with the object of reducing to a minimum, in the case of the electric light, those risks of fire which are inherent to every system of artificial illumination, and also for the guidance of those who possess, and those who contemplate having, electric lighting apparatus on their premises.

It is to be understood these general rules are not intended to supersede any detailed rules which fire offices may issue for their own protection.

It would therefore be desirable that before the electric light is used, notice should be sent to the fire office in which the building is insured, in order that an opportunity may be given for inspecting the installation.

The chief difficulties which beset the electrical engineer are internal and invisible, and they can only be effectually guarded against by testing with special apparatus and electric currents; they arise from leakage and from bad connections and joints, which lead to waste of energy and the production of heat to a dangerous extent.

In addition, the difficulties arising out of defective and inefficient apparatus are numerous; they must be understood and guarded against.

The necessity cannot be too strongly urged for guarding against the presence of moisture, which leads to loss of current and to the destruction of the conductors and apparatus by corrosion and otherwise.

Injudicious connections of any part of the circuit with the "earth" tend to magnify every other source of difficulty and danger.

Many of the dangers in the application of electricity arise from ignorance and inexperience on the part of those who supply and fit up inadequate plant, and frequently from injudicious economy on the part of the user.

The greatest element of safety is, therefore, the employment of skilled and experienced electrical engineers to specify the method in which the work is to be done and the quality of the materials to be employed, and to supervise the execution of the work.

CONDUCTORS.

1. They must have a sectional area and conductivity so proportioned to the work they have to do that, if double the current proposed is sent through them, the temperature of such conductors shall not exceed 150° F.

2. The conductors, or their casings, should be placed in sight, if possible; and they should always be as accessible as circumstances will permit.

3. Within buildings they should all be insulated; and this rule applies equally to all conductors and parts of fittings which may have to be handled.

4. Whatever insulating material is employed, it should not soften until a temperature of 170° F. has been reached, and in all cases the material must be damp-proof.

5. When leads pass through roofs, floors, walls, or partitions, and where they cross or are liable to touch metallic substances, such as bell wires, iron girders, or pipes, they should be thoroughly protected by suitable additional covering; and where they are liable to abrasion from any cause, or to the depredations of rats or mice, they should be encased in some suitable hard material.

6. In the case of portable fittings with which flexible leads are used, special precautions must be taken.

7. Conductors should be kept as far apart as circumstances will permit, the spacing between them being governed by their potential difference.

8. When conductors are carried in very inflammable structures, precautions should be taken to isolate them therefrom.

9. Conductors which are protected on the outside by lead or metallic armour of any kind require the greatest care in fixing, on account of the large conducting surface which would become connected to the core in the event of metallic contact between them.

10. In cases where conductors pass into a building, from one building to another, or from one room to another, precautions should be taken to prevent the possibility of fire or water passing along the course of the conductors.

11. All joints must be mechanically and electrically perfect, to prevent heat being generated at these points. When soldering fluids are used in making joints, the latter should be carefully washed and dried before insulation is applied.

12. Under all circumstances complete metallic circuits must be employed. Gas and water pipes must never form part of the circuit, as their joints are rarely electrically good, and therefore become a source of danger.

13. Overhead conductors, whether passing over or attached

Digitized by Google

to buildings, must be insulated at their points of support. Precautions must be taken to obviate all risk of short-circuiting where they are likely to touch a building or other overhead conductors and wires, either by their own falling or by being fallen upon by other conductors.

14. In the case of overhead wires, every main should have a lightning protector at each point where it enters or branches into a building.

15. Metal fastenings for fixing conductors should be avoided; but, when unavoidable, some additional covering should protect the conductor from mechanical injury at such fixing points.

16. The insulation of a system of distribution should be such that the greatest leakage from any conductor to earth (and, in case of parallel working, from one conductor to the other, when all branches are switched on, but the lamps, motors, &c., removed) does not exceed one five-thousandth part of the total current intended for the supply of the said lamps, motors, &c., the test being made at the usual working electromotive force.

17. It will often be found a great convenience and assistance in the prevention of accidents if the positive lead be coloured differently to the negative, or made otherwise distinguishable.

SWITCHES.

18. Every switch or commutator should be of such construction as to comply with the following condition, namely, that when the handle is moved or turned to and from the positions of "on" and "off," it is impossible for it to remain in any intermediate position, or to permit of a permanent arc, or heating.

19. The handles of every switch must be completely insulated from the circuit.

20. The main switches of a building should be placed as near as possible to the point of entrance of the conductors, or to the generators of the current if they are within the building itself. Switches should be provided on both leads.

21. Switch-boards should bear clear instructions for their use by the inexperienced.

ELECTRICAL FITTINGS GENERALLY.

22. Switches, commutators, resistances, bare connections, lamps, &c., must be mounted on incombustible bases. Cut-outs mounted on bases of wood rendered uninflammable are admissible. Vulcanite bases are undesirable in damp situations. The cracking of porcelain and earthenware fittings is a source of danger which can be avoided by precautions in fixing.

CUT-OUTS.

23. All circuits should be protected with cut-outs; and all leads from the mains, or small conductors from larger ones, must be fitted with cut-outs at their branching points.

24. Where fusible cut-outs are used, the section should be so situated within its frame that the fused metal cannot fall where it may cause a "short-circuit" or an ignition.

25. For all main conductors a cut-out should be provided for both the "flow" and "return," and the two fusible sections must not be in the same compartment.

26. The flexible leads of portable fittings must in all cases be protected by cut-outs at their fixed points of connection.

ARC LAMPS.

27. Arc lamps must always be guarded by lanterns or netted globes, so as to prevent danger from ascending sparks and from falling glass and incandescent pieces of carbon.

28. All parts of the lamps and lanterns which are liable to be handled (except by the persons employed to trim them) should be insulated.

THE DYNAMO.

29. The armatures and field magnet coils should be thoroughly insulated. Dynamos should always be fixed in dry places, and they must not be exposed to dust flyings or other industrial waste products carried in suspension in the air. They should not be permitted in the working rooms of mills, where the liability to such dangers exists, or where any inflammable manufactures are carried on or inflammable materials are stored.

30. Motors should be subject to the same conditions; but when it is necessary to use them in positions such as those above referred to, they must be securely cased in, such cases having a non-combustible lining.

BATTERIES.

31. Both primary and secondary batteries should be placed and used under the same precautions as prescribed for dynamos; and the room in which they are placed should be well ventilated. The batteries themselves must be well insulated.

TRANSFORMERS.

32. When these are used to transform either direct or alternating currents of high electromotive force—that is, from or to an electromotive force of, say, 200 volts—they, together with their switches and cut-outs, must be placed in a fire and moisture proof structure, preferably outside the building for which they are required. No part of such apparatus should be accessible except to the person in charge of their maintenance.

33. In all cases conductors conveying currents of high electromotive force inside buildings must be specially and exceptionally insulated, cased in, and the casing made fireproof.

34. The positive and negative terminals connected to such conductors should not be permitted to be nearer each other than 12 inches.

35. Transformers which, under normal conditions of load, heat above 150° F. should not be permitted to remain in use.

36. Transformers should be so constructed that under no circumstances whatever should a contact between the primary and secondary coils lead the high E M.F. into the building.

MAINTENANCE.

37. The value of frequently testing and inspecting the apparatus and circuits cannot be too strongly urged as a precaution against fire. Records should be kept of all tests, so that any gradual deterioration of the system may be detected.

38. Cleanliness of all parts of the apparatus and fittings is essential to good maintenance.

39. No repairs or alterations must be made when the current is "on."

All the above rules, for the reduction to a minimum of the risks from fire, are also applicable in principle to installations of electricity for other uses than that of lighting; they also include precautions necessary to avoid risk of injury to persons, whether the conductors and apparatus are situated inside or outside a building.

THE LIGHTING OF THE UNION BANK OF LONDON AND RIVER PLATE BANK.

We have recently inspected an installation at the head offices of the above bank which has been put in by Messrs. Verity Bros., to the design of Messrs. Drake and Gorham. In the sub-basement are two 9 horse-power Otto engines driving two Elwell-Parker dynamos, inverted B type, 12 units, running at 750 revolutions. The engines exhaust into pits sunk in the ground, which has a perfect silencing effect, no sound from the exhaust being audible even when standing on the next floor directly over the engine room. Two sets of accumulators, of 53 Elwell-Parker L 23 type, are arranged in a small cellar in Princes-street, and a Blackman air propeller driven by an electric motor ventilates both engine and battery room at the same time. The switch-board is fitted with Drake and Gorham ammeters and ring contact switches, and is divided into two sections, A and B. The lamps throughout the building are arranged so that in each department one-half the lamps (where possible alternate ones) are fed from section A, and the other half from B. The two

Digitized by Google

sections have nominally each their own dynamo and battery, but the boards allow of any desired combination between the two machines, batteries, and sections. All the fuses are on the switch-boards. As it is necessary to provide a certain number of lamps running all night for cleaning, &c., a special arrangement is provided for introducing into the circuit a Cunnynghame cut-out which breaks the main circuit when more than a certain total number of lamps are on, and which cannot re-set until the same are switched off, thus preventing waste after hours. One of Messrs. Drake and Gorham's excess indicators is arranged in each battery circuit, and rings a bell when the proper charging current is exceeded. Passing to the lighting itself, there are altogether some 330 lamps fitted, most of them being half frosted and half plain, which has been found the most economical way of reducing glare. The standards on the desks are of special design, and are very neat and effective. The shade of the lamps is supported by two arms, each carrying a gas burner in case it may be wanted. Where the leads have to be brought through tubes in the fittings special precautions have been taken to avoid any danger from short circuits.

On leaving the Union we then went to the River Plate Bank, to look over a battery there which has been in constant use without any repairs for about eighteen months. This covering two winters' work is a good test, and it speaks well for the secondary battery of the future that in a careful search through the whole set we were only able to find one cell showing even a trace of buckling, and that only to a very slight degree. From the appearance of the cells after two winters' work we should put the life of the positive plates at four years as a minimum, and with cells made now, with another year's experience, we may in reason expect to get longer life still.

ELECTRICAL POWER STORAGE COMPANY (Limited).

Report of the Directors to be presented to the shareholders at the seventh ordinary general meeting, to be held on Thursday, the 19th inst., at Winchester House, Old Broad-street, E.C., at 12:30 p.m.:—

The gross profit for the year is £11,875 1s., derived from the trading of the Company and from royalties and receipts both at home and from the Continent. The Directors have made provision for depreciation of plant, machinery, buildings and doubtful debts, by writing off the sum of £1,569. 1s. 7d.

The above amount, added to the balance to the credit of profit and loss from last year, with the small item of transfer fees, makes the sum of £25,418. 12s. 6d., and after deducting the expenditure of the year and the amount provided for depreciation, &c., a balance remains to the credit of this account of £10,793. 6s. 11d., out of which the Directors propose to place £4,000 to the credit of the reserve fund, leaving a balance of £6.793. 6s. 11d. to be carried forward.

In addition to the above depreciation and reserve a sum of £1,000 has been written off patents account, lessening the gross profit of the year by that amount, while a small increase occurs in this account through the purchase of some other patent interest which it was considered advisable to acquire, but no change in the valuation of the patent interests has been made.

Never before have so many inquiries from all parts of the country been received as during the last two or three months, or have so many negotiations been in progress in connection with the various uses to which the E.P.S. storage batteries are applicable. Central station lighting, tramcar, omnibus and boat propulsion, train lighting, &c.—in each of these branches the inquiries indicate a coming activity in electrical work of a special kind, such as justifies the Directors in confidently looking forward to a large increase in the demand for storage batteries during the current year.

It is much to be regretted that the electrical industry is still fettered by the Act of 1882, but the Bill of Lord Thurlow has been again introduced in the House of Lords, and there is such a concurrence of opinion in favour of an alteration of the Act, that it may be considered tolerably certain that this session will see the much needed changes become law.

The Directors are glad to state that the serious litigation on the Continent is at an end, the Company having succeeded in enforcing the recognition of its rights. Arrangements have recently been completed, by which the manufacture of the E.P.S. battery will be carried on in France, Austria, Hungary and Russia, under payment of royalties, and applications from other countries are now being considered.

In the United States the Electrical Accumulator Company is making very satisfactory progress, and the immediate prospects in the most important branches of that Company's business are of a like character to those in this country.

The Directors are vigilant in protecting the property of the shareholders against all assailants, and they have deemed it necessary to commence an action for infringement of the Company's patents against the Union Electrical Power and Light Company (Limited).

The Company has had its share of permanent installation work, several banks, commercial houses, and private residences in different parts of the country having been satisfactorily lighted. A large amount of temporary lighting has also been carried out.

The application of storage batteries to ship lighting has received more support during the year, and the lighting of railway trains by electricity from storage batteries is receiving considerable attention from the large railway companies, business having been done with several of the leading lines.

A new branch of business—omnibus and carriage lighting—has been initiated with good promise.

A further development of the uses of storage batteries has been made by the Exchange Telegraph Company, who have replaced 2,000 primary batteries with 210 storage cells for working their telegraphic system. These batteries are charged for about a quarter of an hour every day by means of an engine and dynamo, driven from the Hydraulic Company's mains, and after six months' trial they have been pronounced a perfect success.

In motive power a moderate business has been done. Tramcar and boat propulsion are gradually developing, and among other interesting applications of E.P.S. batteries may be mentioned, an electrically driven torpedo, and the experiments in connection with Mr. Eric Bruce's military balloon signalling.

Several important improvements have recently been made in the Company's special manufactures. The form of E.P.S battery known as the "1888" type is considered by the electrical profession as being a great improvement. In this new type the whole of the plates are joined together by metallic bands, so that the battery forms a substantial and rigid set of plates, and the original troubles of short-circuiting and local action have been removed.

A gold medal for an exhibit of batteries and apparatus at the Jubilee Exhibition of the French Railways was awarded to the Company at Paris.

Considerable progress has been made during the year in the perfecting of the arrangements for the application of storage batteries to the public supply of electricity, a pamphlet having been issued by the Company comparing the alternating-current system with the storage-battery system. This pamphlet has appracted much notice, and the statements made in it have been well received, and many of the opponents of the storage system have thought fit to modify their former views.

The question of distribution by continuous-current transformers, which can readily be worked with storage batteries, has also been under the consideration of the Directors, and the Company possesses inventions which it is thought may be of value in the control of the use of storage with this new type of transformer.

The retiring Directors are Mr. Frederick Green and Mr. John Scudamore Sellon, who, being eligible, offer themselves for re-election.

The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also offer themselves for re-election.

JUDGMENT OF THE SUPREME COURT OF THE UNITED STATES IN THE TELEPHONE APPEALS.

(Continued from page 610.)

ALLEGED ANTICIPATION BY DANIEL DRAWBAUGH.

Another alleged anticipation is that of Daniel Drawbaugh. Bell got his patent March 7, 1876, and the fortunate accident which led to his discovery occurred June 2nd, 1875. Active litigation to enforce the patent rights was begun by his company on the 12th of September, 1878, with a suit in the Circuit Court of the United States for the district of Massachusetts, against Peter A. Dowd. This suit was defended by the Western Union Telegraph Company, and vigorously contested. The answer was filed November 4, 1878, setting up alleged anticipation by Gray, Edison, Dolbear and others. The record fills 1,200 printed pages; but before a decision was reached the case was compromised, and a decree entered by consent. The litigation ended some time in the latter part of year 1879. The last deposition was taken on the 19th of September in that year.

The next contested suit was brought in the same court, on the 28th of July, 1880, against Albert Spencer and others. An answer was filed in

Digitized by Google

this case September 6, 1880, and depositions afterwards taken, some of those in the Dowd suit being used in this by stipulation. On the 27th of June, 1881, a decision was announced by Judge Lowell, sustaining the patent, upon which a decree was entered.

On the 14th of November, 1879, Mr. A. G. Tisdel filed in the Patent Office an application for a patent for a new and useful improvement in speaking telephones. On the 18th of November, 1879, Frank A. Klemm also filed an application for a patent for a new and useful improvement in telephone transmitters. These inventions were transferred by assignment to Ernest Marx and Frank A. Klemm, of New York city; — Levy, of Cincinnati; and Simon Wolf, of Washington. On the 6th of March, 1880, these parties entered into a mutual agreement, to the effect that each and all of their interests in said improvements and inventions, and the letters patent to be issued therefor, should be merged and consolidated as the common stock in a corporate body under the laws either of the State of Ohio or New York, or the general laws of the United States, relating to the formation of corporations in the district of Columbia, or in such other States and territories as might be found necessary hereafter. This agreement was recorded in the Patent Office March 10, 1880.

On the 6th of May, 1880, Edgar W. Chellis, a merchant, of Harrisburg, Pennsylvania, H. W. Jacobs, a lawyer of the same place, and Lysander Hill, a lawyer then residing in Washington, in the district of Columbia, made an arrangement with Daniel Drawbaugh, by which they were to become jointly interested with him in his alleged telephone inventions, each to have a quarter interest. Nothing was paid for this, but each of the parties was to have one quarter of anything that should be realised from the enterprise. On the 24th of May, 1880, Simon Wolf, one of the parties interested in the Klemm and Tisdel inventions, visited Harrisburg on business with Chellis in reference to telephone matters. On the 18th of May, six days before this visit, a patent was issued to Wolf and his associates upon the invention of Tisdel. While Wolf was in Harrisburg, negotiations were begun by Chellis for the transfer of the Drawbaugh inventions, and these negotiations resulted in a conditional contract on the 22nd of June, by reason of which Chellis, Jacobs, Hill and Drawbaugh went to Washington. There on the 21st July, 1880, Drawbaugh, claiming to have invented "new and useful improvements in the transmission of vocal speech, and the apparatus to be used for those purposes, for which I am about to make application for letters patent of the United States," assigned to Klemm, Marx, Wolf and Levy, the full and exclusive right to the said inventions as fully set forth and described "in the specifications prepared and executed by me, dated 21st July, 1880, preparatory to obtaining letters patent of the United States therefore." He at the same time and by the same instrument authorised and requested the Commissioner of Patents to issue the patent to his assignees, each as assignee of one quarter part. The specification referred to in the assignment has not been put in evidence in any of the cases. In the course of taking the testimony it was called for by the Bell Company, but the counsel for the opposite party declined to produce either the original or a copy from the Patent Office. The assignment was recorded in the Patent Office July 22nd, 1880, and in the official Digest of Assignments the following notice appears:—

About to make application. Specification dated July 21st, 1880.

On the morning of July 22nd, 1880, the following article appeared in the *Cincinnati Commercial*, a newspaper printed at Cincinnati, Ohio:—

"TELEPHONE COMBINATION.

"Special to the *Cincinnati Commercial.*

"Washington, D. C., July 21.

"An application for a patent was filed to-day, that in consequence of its vastness of interest, as well as wealth of prospect, renders it a subject of national interest. A company of leading business men has been formed that has bought up all the telephone patents antedating those now in use, and known as the Bell, Gray, and Edison patents. The company is composed of leading business men from all parts of the country, Cincinnati being largely represented and interested. The cash capital of the company is $5,000,000, with head-quarters in New York, and in about 60 days they will open up the telephone, which will certainly result in the driving out of all telephones in the market, save the ones they hold, or else in compelling the Gray, Bell and Edison lines to pay the new company a munificent royalty. It appears from the testimony now on file and in the possession of the new company, which is conclusive and exhaustive, that the inventor of the telephone is a poor mechanic, living near Harrisburg, Pa., named Daniel Drawbaugh. Owing to his poverty he was unable to push his patent on the market. The new company have secured and are sole possessors of this invention, antedating those now in use. They are also owners of four patents for telephones issued to Mr. Klemm, of New York. A large number of capitalists were here to-day to see the filing of the application, and they assert, with a positiveness that is almost convincing, that it will not be long till they have entire charge of the telephones, not only in this country but in the world, and that they will be able to establish lines by which messages can be transmitted for almost a song.

"Mr. Lipman Levy, of the law firm of Moulton, Johnson and Levy, of Cincinnati, was here to-day in the interest of the Cincinnati parties, who, as already stated, are among the most prominent financial men of our city."

Afterwards, on the 23rd of August, 1880, the following appeared in the *Journal of Commerce*, a newspaper printed in the City of New York:—

"*A New Telephone Company.*—A company has recently been formed in this city with a capital of $5,000,000 for the purpose of manufacturing telephones. The company is to be known as the People's Telephone Company, and a number of leading capitalists in this city and Cincinnati are interested in it. The telephones are to be manufactured under the patents of Frank A. Klemm and Abner G. Tisdel, and the application for patents of Daniel Drawbaugh, of Eberly's Mills, Cumberland County, Pa., filed July 21st 1880. It is claimed by those interested in the new enterprise that Drawbaugh is really the inventor of the telephone, and had completed one years before Prof. Bell or anyone else had manufactured one. He was, however, in very humble circumstances, and his neighbours, who knew of his experiments, looked upon him as a harmless lunatic. He continued improving his original telephone, and it is claimed that the one which the new company proposes to furnish is superior to any now in use. The company has fitted up a factory in Brooklyn, and in three months will be prepared to supply 1,000 of the new telephones. As soon as operations are actively commenced, it is expected that legal proceedings will be begun against the new company by the Gold and Stock Telegraph Company, which holds most of the existing patents, and a long and interesting legal fight is anticipated."

On the 30th of August, 1880, the People's Telephone Company was incorporated under the general laws of New York, with an authorised capital stock of $5,000,000, for manufacturing, constructing, owning, furnishing, letting and selling telephones and the apparatus used therewith under the inventions and patents of Abner G. Tisdel, Frank A. Klemm, Daniel Drawbaugh, and other inventions and patents which may hereafter be assigned to that company. On the 4th of September, 1880, Klemm, Loth, Marx and Wolf, in consideration of $4,999,550, represented by 99,991 shares of stock, assigned and transferred to that company all their interests in the Klemm, Tisdel and Drawbaugh inventions, those of Drawbaugh being described as "inventions in telephones made by Daniel Drawbaugh, of Eberly's Mills, Cumberland County, Pennsylvania, for which applications for patents were made on or about the 21st of July, 1880, and which were assigned to us on the 31st of July, 1880, as more particularly appears in the deed of assignment, recorded in the United States Patent Office." For the assignment from Drawbaugh to Klemm, Marx, Loth and Wolf, $20,000 was paid in money to Chellis, Jacobs and Hill, and they were allowed to have a certain amount of the stock of the proposed corporation then formed. What amount they actually got, Chellis, who was sworn as a witness in the case, declined to state, but he admitted it was large.

At this time and in this way the attention of the general public was called, for the first time, to the fact that Drawbaugh claimed to have anticipated Bell in the discovery of the telephone. Bell's success had been proclaimed more than four years before, at the Centennial Exhibition in Philadelphia. In the meantime inventions in aid of his discovery had been multiplied. According to the testimony of Park Benjamin, more than 100 patents had been issued and indexed under the word "telephone," and numerous interferences had been declared and considered by the Patent Office. Gray, Edison, Dolbear, and others had either claimed for themselves, or others had claimed for them, priority of invention and discovery, and Bell had thus far been sustained as against them all. Blake had perfected his microphone apparatus, and Bell's patent had become a great commercial success. The People's Company either began or threatened to begin operations under its charter, and on the 20th of October, 1880, the Bell Company brought suit against it in the Circuit Court of the United States for the Southern District of New York, to prevent any infringement of the Bell patent. In the Bill it was alleged that "telephone exchanges now exist in more than 275 towns and cities of the United States, and in every State thereof, and exist in substantially every city having more than 15,000 inhabitants, and in many smaller places. . . . . . That there are now in use more than 100,000 electric speaking telephones, licensed by and paying royalty to the Bell Company; that the owners of the Bell patents, and those who now are or heretofore have been licensees of them, have devoted great time and attention and large sums of money to the development of the telephone and the introduction thereof into extensive use, and to the proper construction of the most suitable telephone lines and systems, and telephonic appliances, and have constructed many thousand miles of telephone lines for use with telephones owned by the Bell Company, and licensed by it for such use; and nothing which the defendants, or F. A. Klemm, A. G. Tisdel or Daniel Drawbaugh have done, has contributed in any substantial way to the development of the telephone or the introduction thereof into use."

The Bill then avers that Klemm, Marx, Levy and Wolf, having become owners of these inventions, and having heard that Drawbaugh claimed that "he had made some experiments relating to electric speaking telephones (which experiments, if made, were incomplete, imperfect, unfruitful, and long before abandoned), entered into an arrangement with him to set up and claim that he was the first inventor of the electric speaking telephone, and to make application for a patent therefor; and that thereafter alleging and pretending that said Drawbaugh was the original and first inventor of the electric speaking telephone, and that electric speaking telephones had not before such application been in public use or on sale for more than two years with the knowledge and consent of Drawbaugh, did on or about the 21st of July, 1880, induce him to make and cause to be filed in the Patent Office of the United States an application for a patent, to issue to them as the assignees of the said Drawbaugh as the first and original inventor of the electric speaking telephone."

It was then further alleged that if Drawbaugh had ever made his pretended inventions they had not been, by him or any one claiming under him, introduced into public use, and "that knowledge thereof has been withheld from your orators and the public, except so far as they have been disclosed within the three months last past by certain newspaper publications."

To this bill the People's Company filed an answer in December, 1880, or January, 1881; the record does not show the precise date. In this

Digitized by Google

answer it was said that Drawbaugh was the original and first inventor and discoverer of the art of communicating articulate speech between distant places by voltaic and magneto electricity, and that long prior to the alleged invention by Bell, Gray, and Edison, he then and now residing at Eberly's Mills, constructed an apparatus which was a practical working electric speaking telephone, at said Eberly's Mills, and exhibited the same in successful operation to a great number of other persons residing in his vicinity and elsewhere; and that his telephones as then constructed and operated contained all the material and substantial parts and inventions patented in the patents of Bell, and also other important and valuable inventions in electric and magneto telephones, and were actually used for transmitting articulate vocal sounds and speech between distant points by means of electric currents; that he had the original instrument which he used and had exhibited to many others long prior to the said alleged inventions of Bell or either of them; that they are still in existence and capable of successful and practical use, and are identified by a large number of persons who personally witnessed their practical operation and use in the years 1870, 1871, 1872, 1873 and 1874, and several years prior and subsequent thereto; that certainly more than fifty and probably not less than one hundred persons, or even more, were cognisant of said Drawbaugh's invention and use of said telephone, and of his claiming to be the original and first inventor thereof prior to the alleged inventions of said Bell or either of them; that said Drawbaugh for more than ten years prior to the year 1880 was miserably poor, in debt, with a large and helpless family dependent upon his daily labour, and was from that cause alone utterly unable to patent his invention or caveat it, or manufacture and introduce it on the market; that said Drawbaugh never abandoned the said invention nor acknowledged the claim of any other person or persons thereto, but always persisted in his claims and intended to patent it as soon as he could procure the necessary means therefor. That said Drawbaugh never acquiesced in the public use of said Bell, Gray, Edison, Blake, or other telephones, nor in the claims of the alleged inventors nor gave his consent to such use.

It is then said that Drawbaugh, after finding by experiment that his invention was capable of successful working, conceived that its range and capacity for usefulness to the public might be greatly enlarged, and that many improvements of great value might be made and added to it, which without departing from its principle, might increase its value to himself and to the public; and therefore set himself to work to discover and invent such improvements; that he discovered and invented some such improvements prior to any alleged invention by the said Bell; and then, notwithstanding his embarrassed and impoverished pecuniary condition, and his utter want of proper mechanical tools, materials and appliances to conduct such work, he laboured with all reasonable diligence to perfect and adapt his said improvements, and did finally, in due exercise of such reasonable diligence, perfect and adapt the same; and that, in so far as the said Bell has incorporated such improvements in his said two patents, or either of them, he (the said Bell) has surreptitiously and unjustly obtained a patent or patents for that which was in fact first invented by said Drawbaugh, who was using reasonable diligence in perfecting and adapting the same; and therefore the patent or patents of the said Bell therefor is, or are, invalid and void.

It is then said that "the defendant, relying upon his legal rights, caused application to be made and filed in the Patent Office for the invention of the said Daniel Drawbaugh, with the intention of procuring interference proceedings to be instituted in accordance with the statute, against the patents of said Bell, and the pending applications of said Gray, Edison and others, in order that said Drawbaugh might be adjudged by the Commissioner of Patents to be the original and first inventor of the electric speaking telephone, and might be adjudged entitled to receive a patent or patents therefor."

The People's Company began taking depositions on the 19th of April, 1881, but Drawbaugh himself did not appear as a witness until December 7th, 1881. After that time others were examined, and when the proofs were closed, between three and four hundred witnesses had been produced whose testimony was taken and put into the record to establish the priority of Drawbaugh's invention. This testimony, as is now claimed, shows the story of that invention to have been as follows:—

"Early conception and experiments with a continuous current, 1862 and 1866 and 1867.

"Tea cup transmitter and receiver, 1866 and 1867.

"Tumbler, tea cup and mustard can, F and D, 1867 and 1869.

"Improvement on B, namely, C, 1869 and 1870.

"Further improvements on C and the more perfect magneto-instrument I, 1870 and 1871.

"Mouth-piece changed to centre and adjusting screw inserted (exhibit A), 1874.

"D and E, perfectly adjusted and finished magneto-instruments, January and February, 1875.

"L, M, G and O, February, 1875, to August, 1876.

"H, August, 1876.

"J, N and P, 1878."

This statement of the Drawbaugh claim we have quoted from the brief of counsel appearing in his behalf, and his success in the litigation has been based, as we understand it, both in the answer and in the argument, on the truth or falsehood of what is thus set forth.

The letters F and D, &c., in the statement refer to exhibits in the case, being certain instruments claimed to have been made and used by Drawbaugh in the progress of his work, and preserved until now. The original tea cup instrument was not produced, but Drawbaugh gave in his deposition what he said was a drawing showing how it had been constructed. F, B, C, D, I and A were neither of them in a condition for use when they were put in evidence, and none of the witnesses except Drawbaugh could tell how they were originally constructed, or what the process was by which sound was transmitted when they were used. All that any of the witnesses could say on that subject was that they had used one or more of the different instruments at Drawbaugh's shop, and heard sounds and sometimes words spoken to them, and that Drawbaugh told them the sound was carried on the wire by electricity. There was nothing whatever produced in print or in writing on the subject, nor even a memorandum or drawing of any kind, and there is nothing in the testimony to show that Drawbaugh ever told any one how his earlier instruments were made, or what his process was, until he was called as a witness in December, 1881, and explained it in his testimony. This was nearly twenty years, according to the present claim, after he had begun his experiments, nearly seven years after he had made and used D and G, perfectly adjusted and finished magneto instruments, more than five years after L, M, G, O and H had been constructed and connected in his shop, if his story is true. It was also nearly six years after the date of Bell's patent, more than five years after the success of his discovery had been proclaimed at the Centennial Exhibition in Philadelphia, four years after his invention had gone into public use, three years after it had become an established success, and two years after he had brought the first suit for the establishment of his right against Dowd, who represented the Western Union Telegraph Company, to a successful termination.

(To be continued.)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 31st*, 1888.

The annual meeting of the American Bell Telephone Company was held at Boston on March 27th. The statistics presented show a steady growth, nearly all the sub-companies having increased their plant and business. There are now 743 exchanges, or seven more than last year, and 444 branch offices, or two less than last year. There are 127,902 miles of wire and poles in telephone service all over the country, 9,458 miles of wire on buildings, 8,009 miles of wire underground, and 363 miles of submarine wire. The extra territorial lines now number 927, with 32,478 miles of pole line and 56,179 miles of wire. The exchanges employ a force of 6,182 people, and have 158,732 subscribers. There were in the hands of licensees 380,277 instruments, being an increase for the year of 26,759. The estimated number of exchange connections every day is 1,011,517, or the immense total for the year of 369,203,705. The daily number of calls per subscriber averages 6·37, being an increase over last year of 9 per cent., and the average cost to the subscriber ranges from 2 to 8 cents a connection, which in view of the convenience afforded is a very small outlay. The finances of the company are, it is needless to state, in excellent shape. The treasurer's statement shows gross earnings from all sources of $3,453,027, and expenses $1,242,430, leaving, with miscellaneous credits, a clear income of $2,237,608. The dividends paid during the year out of this sum amounted to $1,568,336, and there was a total surplus at the end of the year of just over $2,000,000. The report makes only a passing reference to the recent decision in the telephone case, and to the legislation attempted for regulating telephone charges. Speaking of the long-distance service, it is stated that there are now a total of 550 miles of pole lines and 10,000 miles of wire, the success, electrically as well as commercially, being beyond expectations. The income from these lines already has been more than sufficient to meet expenses, and a moderate profit is expected during the current year. The remark is made:—"The great cost of the plant is to be borne in mind in considering the direct profit from the long-line service, but the importance of the system as a safeguard to our business cannot be overestimated." The expense of completing the lines between New York and Boston, and extending from Albany towards Buffalo, as well as building the line from Chicago to Milwaukee is put at about a million dollars.

The above shows a state of affairs that must be very encouraging to the stockholders as indicating the stability of the concern and its remarkable earning capacity. At the same time, the sensitiveness of a stock that is based upon patent rights was strikingly shown last week, when upon news of the sudden death of Chief Justice Waite, of the Supreme Court, the quotations fell from 260 to 245, the reason of this being

Digitized by Google

that the reconstitution of the court with the new judge added to it might be hurtful to the Bell interests. The argument may seem rather far-fetched, but it was sufficient to "bear" the stock.

Reference has been made above to the long-distance telephone lines as being a "safeguard to the business." It is not easy to determine just in what sense the phrase should be interpreted, but the general idea amongst electricians is that the service is not so much a defence for the American Bell Telephone Company as an offence to the Western Union Company. The lines have reached all the important points in the East, work is to be begun actively in the West, and whether it be true or not there are plenty of reports to the effect that the Western Union Company views these advances with suspicion. It is even said that the Western Union Company watches closely as to the leasing of these long-distance lines to brokers and others, and in one recent case actually made one of its customers decide outright to use either the telegraph or the telephone, the result being that the firm in question did not adopt the telephone service as it proposed. The private line service of the Western Union Company is very profitable, and hence the care with which it is protected. But it is evident that the encroachments of the telephone upon the telegraph field do not stop here, and that, as the recent blizzard exemplified, the telephone can prove a very efficient substitute for the telegraph in all work. The promptness with which the connection is effected more than offsets the higher rate of charge. This condition of affairs in America has, of course, its direct bearing on the situation in England, and the movement there for the buying out of the telephone companies by the Government is watched with interest here by many.

Mr. Jay Gould has signalised his return from Europe in a very sensational way. As you may be aware, an effort has been made to indict him and Mr. Russell Sage for alleged misappropriation of railroad moneys to the extent of about five or six million dollars. Nothing practically, has been accomplished in the matter up to the present time, nor do I think it likely that anything will be; but Mr. Gould has come out with the charge that an attempt has been made to render him the victim of a blackmailing scheme, and that the "motives" behind the criminal prosecution are "a newspaper, a cable company, and a woman." People are very much interested to know what all this pother means, and what is actually at the bottom of Mr. Gould's accusations. The Commercial Cable Company says that it practically knows nothing about the indictment hanging over Mr. Gould, whose assertion is intended really, it thinks, to have an influence in England. The *Herald* may, of course, justify its attacks on Mr. Gould upon the ground of public policy, but how all the various anti-Gould elements are allied and mixed up in this matter nobody seems to know.

The bids for city lighting in New York for next year have just been filed, and it is cheering to note that as far as electric lighting is concerned they all strike a much higher average than they did last year, when cut-rate competition prevailed, and prices were reduced far below their proper level. The companies this year tender at from 32 to 59 cents per arc lamp per night, and the average of the bids seems to lie around 40 cents, which is generally regarded here as a fair price. No contracts have yet been awarded, but it is safe to expect that when made they will be on a better basis. When the bids were presented the mayor made an inquiry as to why one of the companies had failed to furnish lights under its contract, and was informed that the Board of Electrical Control had refused the company the privilege of putting up the necessary poles and wires; under these circumstances it was obvious that the company could not very well carry out its contract. This year, however, the deadlock will probably be broken. A good deal of opposition to the Subway Board is still shown in this city, and it found expression last week when the Postal Telegraph and Cable Company, and one or two others under practically the same management, obtained an injunction preventing the Board from selling them out, because they would not pay the amount assessed on them to meet the expenses of the Board. The taxation referred to is opposed on various grounds, the chief of which are that the expenses of the commission are far too high, and that the assessments are levied without being fairly divided up amongst the companies liable.

Dr. Norvin Green made an interesting statement this week before the United States Senate Committee on Inter-State Commerce, which now has in hand the Spooner Inter-State Telegraph Bill, of which I have already sent you some particulars. He mentioned the fact that the Western Union Company has contracts with 600 railroads for which free and half-price service was rendered in return for transportation, and suggested various amendments in the provisions proposed by the Bill to meet the conditions of the case in that respect as well as in others. He was desirous of seeing a clause to settle the liability of the company to produce telegrams under subpœnas from courts, &c., and was also wishful of having a limit set to the amount of damages that could be collected for the delay in the transmission of messages. Col. Robt. Ingersoll appeared before the committee on behalf of the Postal Company, and I judge from the tenor of the inquiry and the drift of things, that the agitation for Government telegraphs may simmer down this year into the adoption of the Inter-State Bill.

The effect of the Bell telephone decision has been to encourage the makers and vendors of acoustic telephones to new efforts, and to direct attention again to systems of telautography. Prof. Elisha Gray, for instance, is putting forward a telautograph which is to make amends to him for the telephone, out of which he considers himself to have been defrauded. He says that with this apparatus, which will not cost more than $15 or $20, and is easily kept in order, full written communication can be had through the usual switchboard arrangements, between any number of persons, as in a telephone exchange system. I hear that capitalists are looking into the matter, and that early practical developments may be expected. As you are aware, a device of this kind, known as the "writing telegraph," has been exploited here recently, and was introduced in Rochester, Pittsburg, and one or two other places, but I cannot ascertain anything that would establish it as a present great success. Evidently the thing is worth striving after, and the complete invention, giving easy means of conversation and record, would be very valuable, in America at any rate.

Strenuous attempts are still being made here by the Stock Exchange and legislators to crush out the "bucket shops," where gambling in fractional stocks is indulged in; but, like the telegraph schools, the bucket shops live on. The evil has lately made itself felt in Canada, and a Bill has been introduced this week in the Dominion Senate at Ottawa of a very severe character, proposing to inflict on anyone who may be engaged in bucket-shop transactions a fine of £1,000, or five years' imprisonment, and on frequenters of the places imprisonment of at least a year.

NOTES FROM STOCKHOLM.

(FROM OUR OWN CORRESPONDENT.)

The Malmö Electric Light Company, Malmö, Sweden, held its first annual meeting on Tuesday, April 3. The directors stated that the cost of erection amounted to 44,730kr., or about £2,500. There were two steam engines, each of 42 horse-power, and three dynamos, two with a capacity of 435 lamps, and one with a capacity of 140 lamps. As the installation had not been completed at the time originally intended (last autumn) only two arc lamps and 704 incandescent lamps had hitherto been taken in use, though additional subscribers for some 200 lamps were confidently reckoned upon within some little time.

The Electric Company (Limited), Stockholm (Elektriske Aktiebalaget, Stockholm) held its annual meeting in the Stockholm Exchange, on Wednesday, April 4th. The report states that the business of the company increases for every year. During the year 1887 the company's new installations comprised over 2,650 incan-

Digitized by Google

descent lamps, against a total of 5,300 incandescent lamps during the previous four years. The power at the works of the company at Arbaga is transmitted by dynamos, which is the only instance of the kind in Sweden. This arrangement has been in force for rather more than a year, and has given entire satisfaction. Last year's profits amounted to 10,036kr., which it was decided to add to the capital of the company. Mr. Ludvig Fredholm was re-elected as managing director, and Prof. J. E. Cederblain and Mr. Auz. Mueller as co-directors.

The Swedish Diet is experiencing some difficulty in arriving at a result with regard to the proposed telephone tax, one Chamber having voted in favour of it and the other against it. The matter will now be settled by a joint voting of both Chambers.

The Bell Telephone Company, of Gothenburg, passed on the 1st of April into the possession of the State Telegraphs, both as regards stations and wires within Gothenburg and the connections with places outside the town. Mr. V. Brusevitz will continue to manage the telephone station.

The Swedish Government has issued an order that all the pupils at the mine section of the military school at Karlskrona shall be instructed in practically tending electric lamps, both arc and incandescent. The necessary appliances and funds have been placed at the school's disposal.

CORRESPONDENCE.

SMALL DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have a small dynamo of the Gramme type, having 12 teeth in the armature, wound on the field-magnets with 6lb. No. 22 S.W.G. (R = about 30 ohms), and on the ring 7oz. No. 20 S.W.G. (R = about ·87 ohm). I can by no means obtain a current from this machine worth speaking of at 1,300 revolutions. Would someone more proficient than myself kindly point out the probable source of my error, and say if I ought to alter size or length of wire, speed, &c., and when altered and set up as it should be, the number of 10 candle-power lamps this machine *ought* to light? Hoping that my wants, which I know are many, have not led me to ask too much.—Yours, &c.

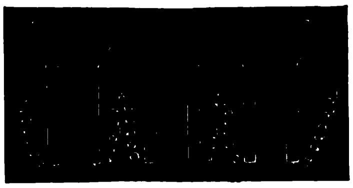
ONE OF THE UNPROFESSIONAL READERS.

[It is not possible to give a definite answer to our correspondent's inquiry from the meagre information contained in his letter. The machine is evidently intended to have the field coils connected in shunt with the armature—possibly he has joined them up in series. Other things being equal, the *current* obtainable depends solely on the heating of the armature, but this depends on several things besides size of wire. Probably about three amperes, or say three or four 10 candle-power lamps at 50 volts, would in this case be the maximum safe load. Whether the machine may be expected to give 50 volts at 1,300 revolutions it is impossible to say without further information. If, however, our correspondent cares to send us drawings, with detailed dimensions, we shall be pleased to go further into the question, and to communicate with him by letter.—ED. *E.*]

CONSTRUCTION OF RESISTANCE COIL BOXES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In one of your recent issues under the head of "Letters for Learners and Un-Professional Readers" the instructions are given for the construction of resistance sets in which the coils are represented as being connected to a rod or post attached to the block on the cover of the instrument, there being only one post to each block, and the two terminals of the two adjacent coils attached to this. I want to call attention to the error introduced by constructing boxes in this way, especially because I myself once had a box, made by makers of great reputation in the manufacture of electrical apparatus, in which the coils were so connected, and it led me into considerable trouble before I found it out. The difficulty is this, that when any one of the coils is used alone, the two posts enter as a part of its resistance, but when successive coils are used in series, only the first and last post enter into the resistance of the series, and the coils, therefore, do not sum up exactly, as they measure separately. The error, of course, is of little consequence except in the case of coils whose resistance is small, but in the case of ohms the error is quite appreciable, and even in 10-ohm coils the difference can be detected when measurements are made with extreme accuracy, and in case of 10-ohm coils the difference is a very considerable percentage of the whole.



The proper method of construction is to connect two posts with each block, and then connect the terminals of one coil to one post and of the other coil to the other, as shown in the accompanying sketch; and in the construction of resistance boxes for very accurate work the writer has made the posts for all the coils up to and including 10 ohms of German silver, in order that errors due to a variable temperature coefficient might not enter to change the values.—Yours, &c.,

April 2nd, 1888. WM. A. ANTHONY.

THE SALE OF TELEPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Swinton's letter in your last issue clearly refers to our advertisement, and, being very misleading, calls for a reply.

The armature used by Mr. Swinton in his receivers consists of an iron strip, fixed at each end to the two metal rings, between which the diaphragm is held. If the diaphragm be entirely removed, the armature will remain self-supporting. We understand it is on this point that the United Company attack Mr. Swinton's receivers.

It would be inferred from Mr. Swinton's letter that our receivers are similar to his own, but they are not. Mr. Moulton, Q.C., who has fought on the United Company's side in all or most of their battles, has given his decided opinion that the Stanhope telephone does *not* infringe Bell's patent, and his opinion is supported by other eminent counsel.

We fail to see Mr. Swinton's motive in writing the letter referred to, which would more naturally have come from the plaintiff company had there been any ground for it.—Yours, &c., JOHN S. SAWREY, Managing Director.

The Stanhope Company (Limited), April 10, 1888.

ON A GLASS CONDENSER.*

BY J. LEHMANN.

The author had noticed that a Leyden jar apparently required fewer turns of a frictional machine to charge it to a given potential after it had been standing idle for some time than when it had been frequently charged and discharged. He thereupon constructed a condenser of glass plates about 1 square inch surface and ·0008 inch (·02mm.) thick. These he coated on *both* sides with silver, and thus ensured that the metal was everywhere in intimate contact with the glass, thus avoiding a possible error due to air acting partially as the dielectric. The silver was removed round the edges of the plates with nitric acid and connections made by strips of tin foil. Three such plates were used and found to have a capacity of 0·023 micros. at 20deg. C.

The standard condenser with which this was compared was (apparently) a paper one, and had a capacity of 0·3 microfarad. The charging battery was 5 Daniell cells. The scale readings were proportional to a fraction of one division for from 1 to 10 Daniells. The following table shows the behaviour of the two condensers (after being earthed for 24 hours beforehand).

* Abstracted from the *Centralblatt für Elect. Tech.*

Digitized by Google

The mark * means that the charge was as instantaneous as possible, the discharge following immediately.

TABLE I.

Standard Condenser.		Glass Condenser.	
Length of Charge.	Throw.	Length of Charge.	Throw.
*	652	*	44
30 sec.	655	10 sec.	52
*	652	*	44
1 min.	656	1 min.	50
*	656	*	49·5
*	655	*	48
	etc.		etc.
*	652	*	44
2 min.	656	2 min.	50
*	655	*	49
	etc.		etc.
*	652	*	44
Maximum increase = 4 in 652 = 0·61%		Maximum increase 8 in 44 = 18·2%	

The author considers the results may be equally well explained on the theory of permeation of charge, or on Kohlrausch's theory of polarised molecules.

The glass condenser was then charged for varying times, discharged, insulated for ten seconds, and then the throw due to residual charge was taken.

TABLE II.

Time of Charge.	Throw of Residual.
*	4
1	5·5
2	6
4	10
6	11
8	12
10	12·8
15	13
30	14

There was considerable loss of charge due to conduction through the glass. The author goes into considerable detail on this point; suffice it to say that he found this loss at −3deg. to be from ⅓ to ½ that at +20deg.

A long series of tests then shows the relation between temperature and capacity, which we can only give in brief. For the higher temperatures one plate was used; for the lower set, three.

Temperature.	Discharge Throw.	Temperature.	Discharge Throw.
+20	16	+20	50
30	22	0	40·5
40	30	−10	35
50	46	−25	33·2
60	91	−35	32·9
70	178		
80	265		
90	394		
100	722		

The following table is curious, showing that at low temperature the residual appears to vanish:—

Temperature.		95°	50°	20°	0°	−10°
Charged for 10sec.;	throw =	425	40	15·3	12·5	11·5
„ 5sec.	„	335	38	15	12·4	11·5
„ *	„	195	36	13·8	12·2	11·5

Strong heating or cooling appears, says the author, to have an effect on the dielectric qualities of the glass which lasts for a considerable time. To this point he hopes to return in a future paper.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

4,844. W. P. THOMPSON. Liverpool. Improvements in or relating to holders for incandescent electric lamps by which they are made applicable as combined holders and circuit closers and breakers (N. E. Garczynski). March 31, 1888.

4,875. A. WILSON and J. F. SAFE. London. Improvements in machinery for raising and lowering submarine telegraph or other cables. March 31, 1888.

4,909. J. C. FELL. London. An improved telephonic apparatus (P. C. C. Otzen, Denmark). March 31, 1888.

4,929. W. GILLETT and G. HASELTINE. London. Improvements in magneto-electric generators. April 3, 1888.

4,940. T. PARKER. Manchester. Improvements in and relating to alternating-current dynamo electric machines. April 3, 1888.

4,964. A. J. BOULT. London. Improvements in apparatus for the changing and regulating of electric currents (S. Doubrava, Austria). April 3, 1888.

5,029. A. H. MOBSBY and A. F. DAVIES. London. Generation of electricity by tidal or river power. April 4, 1888.

5,069. C. A. RANDALL. London. A combined mechanical and electromagnetic motor. April 5, 1888.

5,082. R. P. SELLON and R. C. JACKSON. London. Electricity meters. April 5, 1888.

5,098. P. L. KRICBOOM. London. Method of and apparatus for electrical signalling or announcing in connection with telephone circuits. April 5, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the dates in italics, give notice at the Patent Office in the prescribed form of such opposition.*

April 7, 1888.

6,104. A. LE NEVE FOSTER and F. V. ANDERSEN, London. Improvements in electrical measuring instruments. April 26, 1887.

6,219. J. SWINBURNE, Chelmsford. Improvements in or connected with induction apparatus and the use of it in studying dynamo electric machines. April 26, 1887.

7,184. W. MACKIE, London. Improvements in electric arc lamps. May 17, 1887.

7,982. C. L. W. FITZGERALD, London. Improvements in or additions to telephonic instruments for enabling them to be used only on prepayment for such use. June 2, 1887.

7,950. D. J. SMITH and H. F. JACKSON, London. Improvements in or connected with telephones for indicating and recording the number of times that a telephonic instrument is used for ascertaining payments due or for other purposes. June 1, 1887.

8,159. W. SMITH, London. Improvements in effecting electric telegraphic communication applicable especially for telegraphing to lighthouses, either floating or on rocks, at a distance from the shore or for telegraphing to or from vessels. June 7, 1887.

2,179. M. WHEELER, London. Improvements in incandescent electric lamps. February 13, 1888.

2,246 H. H. LAKE, London. Improvements relating to dynamo electric machines (R. Eickemeyer, United States). February 14, 1888.

2,250. J. H. LINVILLE, London. Improvements in printing telegraphs. February 14, 1888.

2,308. C. COERPER, London. Improvements relating to dynamo electric machines. February 15, 1888.

PATENTS SEALED.

April 6, 1888.

747. F. WYNNE. London. Means or apparatus to be employed in the application of electricity to propel vehicles on roads with or without tram or other rails. January 17, 1887.

LEGAL INTELLIGENCE.

Avery v. National Company for the Distribution of Electricity by Secondary Generators (Limited).

This was an action to recover £250, money lent, and for an order compelling the defendant company to register the plaintiff as a holder of 200 Preference and 100 Ordinary shares, and also for an account of dividends and profits due.

Mr. Cripps and Mr. Ellis appeared for the plaintiff; Mr. Muir Mackenzie for the defendants.

The facts of the case were as follows:—The plaintiff is the administrator with the will annexed, and also a creditor of the late George Michael Maurice Yvers Le Fez, a Frenchman resident in London, who was a director of the defendant company, and at the time of his death credited in the books of the company with the sum of £250, money lent to the company, and also appeared on the register as the holder of 200 Preference shares and 100 Ordinary shares. Le Fez was acquainted with the Count and Countess de Rocquigny, who were then residing in London, and was their debtor. On October 15th, 1884, Le Fez wrote a letter to the directors of the defendant company resigning his directorship and authorising them to transfer the whole of the shares standing in his name into the name of the Countess de Rocquigny, and also assigning the debt for £250 to her. Le Fez committed suicide on October 17, leaving a will dated October 16, 1884, which was made according to French law and proved in Paris. After the death of Le Fez the above letter of October 15 was found in his room, and was taken to the directors on October 23 by Mr. V. Williams, who was then acting as solicitor for the countess. The directors refused at first to make the transfer, and the shares and debt were not transferred into the name of the Countess until February, 1885. The case now set up on behalf of the plaintiff was that the letter of October 15 was not a legal transfer of the shares, and was never delivered by Le Fez to the company, and that the transfer so improperly made should be set aside.

Mr. Justice MATHEW having summed up, the jury almost immediately returned a verdict for the defendants.

COMPANIES' MEETINGS & REPORTS.

The Telephone Company of Ireland (Limited).

The ninth ordinary general meeting of the proprietors of this Company was held at the offices of the Company, Commercial-buildings, Dean-street, Dublin, on Monday last.

Mr. V. B. DILLON, solicitor to the Company, was in attendance.

Mr. JOSEPH BOND MORGAN, in moving that the High Sheriff, Alderman Winstanley, should take the chair, said they regretted exceedingly that they had not amongst them their late chairman, Mr. Edmund Dwyer Gray. The Telephone Company would miss him immensely, for he was a great power not only in that Company but also in respect of the assistance which as a member of Parliament he rendered to telephone interests generally. He took a very active part in a special committee ordered by Parliament to consider the position of the telephone companies in relation to a Bill in which they sought to obtain the power of way-leaves. His action in the matter had been of great service to telephone interests, and the matter was now being pressed with great vigour, and they trusted that material benefits would result to the companies.

Mr. HERMANN G. ERICHSEN, in seconding the motion, said he would only repeat what had been said in the public prints of Mr. Gray—namely, that he was a most honest, honourable, amiable, and, he would add, able man.

Alderman WINSTANLEY, having taken the chair, moved the adoption of the report, which has been already published, and the accounts. He could not do so without alluding to the great loss which that and other telephone companies had sustained by the death of their late lamented Chairman. He was a man the like of whom they seldom met. Not only was he an excellent man of business, but he was a man well known throughout the entire of the United Kingdom. In his business capacity, as a literary man, and as an orator, he adorned everything that he touched, and brought to whatever he undertook an amount of intelligence, perseverance, and industry that guaranteed success. They had always found him an excellent member of the Board of that Company, for whenever they found themselves in a difficulty they had only to refer to him in order to be assisted through, and enabled to carry whatever they had in hand to a successful issue. Much had been said of him in the public press of England, Ireland, and Scotland, but not a word more than he deserved. With regard to the report, the figures which it contained spoke for themselves, and showed that the Company had been fairly successful during the year. They obtained 73 new subscribers during the year, but lost 52 by deaths and other causes, which left a net increase of 21. During the first couple of years they did not write off any bad debts; in fact, they thought their business would not lead to any, but they found it impossible to avoid them. From deaths, failures, and one cause or another they made something over £100 a year of bad debts, and these accumulated to £323. 7s. 6d.; but in the year 1887 they had not only written off the whole of that amount, so as to be able to start fair in 1888, but they had also been able to put 10 per cent. of their earnings to their reserve fund and to carry a considerable sum forward. They had also made such arrangements as would, he believed, enable them to avoid bad debts in future, or at all events to incur very few. Arrears were no longer allowed to accumulate in the Post Office royalty, which was payable in advance. Their business was now on a sounder basis than it had been in any previous year, and all doubtful proposals were declined, except on such terms as would ensure the Company against loss. It was a matter of congratulation to the shareholders that the gross revenue of the Dublin exchange for the past year had been upwards of £10,000. In the year 1884 it was under £5,000, so that in three years it had increased at the rate of 400 per cent. That was a satisfactory and remarkable development, and it would be more pronounced but for the obstruction which they still received from the Postal Telegraph Department. The Directors would have long since established call offices at all the suburban railway stations and at the suburban post offices where no telegraph existed, but for the refusal of the Post Office to give their consent—a policy which he considered wholly inexplicable. It was to be hoped, however, that the Postmaster-General would soon give them a fair field, and that the heavy tax of 10 per cent. on their gross revenue would be removed, and every possible facility given for their operations, for it was a scandal that what had become a necessity for all business pursuits should be subject to the existing tax upon it. It was also very hard that the Government should arbitrarily refuse the Company leave to have call offices at the railway stations merely because the former claimed exclusive rights for telegraphic purposes. In addition, if the Telephone Company wanted to cross a railway or to go along its banks they were charged an extra tax besides the 10 per cent. royalty on their gross income in consequence of this claim of the Government to the exclusive use of the railways for telegraphic purposes. In this connection the Company would greatly miss the energy and ability of their late Chairman, who was deeply interested in the removal of the obstructions placed in the way of the development of the telephone system, in which he took an absorbing interest, and who had done great service not only to that Company, but to the telephone world in general by his action in Parliament and the interviews which he had with the Postmaster-General on various occasions.

Mr. ERICHSEN seconded the motion, which was unanimously agreed to.

The CHAIRMAN moved a resolution striking a dividend at the rate of 1 per cent. per annum on the ordinary share capital of the Company, and confirming an ad interim dividend of ½ per cent. per annum struck last August.

Mr. ERICHSEN seconded the motion, which passed unanimously.

On the motion of Mr. MORGAN, seconded by Mr. DUDGEON, the retiring directors, Mr. Erichsen and Alderman Winstanley, were re-elected.

On the motion of Mr. HOPKINS, seconded by Mr. JAMES M'GOLDRICK, the retiring auditor, Mr. John M'Kean, was re-elected, and the remuneration of the two auditors was fixed at 50 guineas for the year for both.

The proceedings then terminated.

Oriental Telephone Company (Limited).

Report of the Directors for the year ended 31st December, 1887, to be presented at the eighth ordinary general meeting of the Company, to be held at the City Terminus Hotel, Cannon-street, E.C., on Wednesday, the 25th inst., at 1 o'clock.

The revenue account for the year exhibits a balance to credit of £5,854. 15s. 10d., which has been transferred to the profit and loss account. To this amount has to be added the sum of £4,769. 11s. 3d. brought forward from last year, making a total sum to credit of profit and loss of £10,624. 7s. 1d. In accordance with previous balance-sheets the Indian guarantees for the year, viz., £2,406. 18s. 11d., have been debited to this account.

The Directors have deemed it advisable to reduce the item of preliminary expenses, and have consequently written off a sum of £1,128 in respect of these. They have further written off £259. 7s. 10d. for depreciation of stores at the various branches, and £121. 3s. 3d. in final settlement of losses on shipments of instruments to Australia on joint account, dating from 1882, with the Consolidated Telephone Construction and Maintenance Company (Limited).

The nett balance, therefore, to credit of profit and loss, after deducting the above items, is £6,708. 17s. 1d.

The Directors recommend a dividend for the past year of 2½ per cent., free of income-tax, on the paid-up capital of the Company other than the vendor's shares. This dividend will absorb £3,106. 1s., and leave £3,602. 16s. 1d. to be carried forward.

The Telephone Company of Egypt continues to make satisfactory progress, and the dividend of 6 per cent. declared by that company for the past year on its preferred capital has been brought into the present accounts.

The revenues of the Indian subsidiary companies are maintained. The Deferred shares held by this Company will this year rank for dividend as well as the Preferred shares.

The China and Japan Company has, as was anticipated in last year's report, been able to finally extinguish the deficit arising on previous years' workings, pay its debenture interest and carry a small sum forward.

The exchanges worked by the Company all show a profit for the year. In order to give the most efficient service at Rangoon, the Magneto system is now being introduced. This completes the change of system throughout the Indian exchanges.

The retiring directors are the Right Honourable G. A. F. Cavendish-Bentinck, M.P., and B. St. John Ackers, Esq., both of whom are eligible and offer themselves for re-election.

Messrs. Deloitte, Dever, Griffiths and Co., the auditors of the Company, retire and also offer themselves for re-election.

Montevidean and Brazilian Telegraph Company (Limited).

Directors' report to be submitted at the ordinary general meeting to be held at the Company's offices, 2, Tokenhouse-buildings, London, E.C., on Monday, the 16th inst., at one o'clock:—

The percentage of gross revenue receivable from the Western and Brazilian Company shows a slight increase, being £2,508. 9s. 1d., as compared with £2,370. 6s. 5d. in 1886.

The Directors had hoped from the improved condition of trade with South America that they would have been able to report a more favourable result to the shareholders.

The Directors are glad to observe that, so far as can be judged from the published returns of the Western and Brazilian Telegraph Company, there appears some prospect of a greater improvement in the traffic during the current year.

The shareholders will remember that the debentures issued in 1876 were made redeemable on the 1st of July, 1896. There being a balance of £10,280 still unredeemed, it will be necessary to set aside annually a larger sum for the purpose of redemption than hitherto, and the Directors therefore propose to appropriate £1,000 for that purpose for the year 1887, which leaves a balance of £474. 7s. 11d. available for division.

The Directors recommend the payment of a dividend at the rate of 1s. per share on the Preference shares of the Company, which will absorb £415. 14s. 0d., leaving a balance of £58. 13s. 11d. to be carried forward to next account.

The Directors regret to inform the shareholders that Sir Thomas Gore Browne, K.C.M.G., C.B., who so long occupied the position of Chairman of the Company, died in the month of April, 1887.

Mr. James Joicey, M.P. (whose interest in the Company as a shareholder is larger than that of any other gentleman), was appointed a Director of the Company, to fill the vacancy left by the death of Sir Thomas Gore Browne.

The retiring Director is Dr. Charles Cameron, M.P., who being eligible offers himself for re-election.

The auditor, Mr. W. S. Ogle, chartered accountant, also retires, and offers himself for re-election.

NEW COMPANIES REGISTERED.

TUNBRIDGE WELLS ELECTRIC LIGHT COMPANY (LIMITED).—This company was registered on the 29th ult., with a capital of £30,000, in £5 shares, to carry on, at Tunbridge Wells, the business of an electric light company, in all branches, and also the business of a telephone company. The subscribers are:—

	Shares.
H. T. Chetwynd Stapylton, J.P., 72, Warwick-square	10
W. H. Hodkin, Tunbridge Wells, banker	1
G. Chaverton, Tunbridge Wells, chemist	1
E. Durant, Tunbridge Wells, grocer	1
E. Waymark, Tunbridge Wells, draper	1
B. C. Colls, Tunbridge Wells, tailor	1
E. A. Hallingham, Tunbridge Wells, veterinary surgeon	1

The number of directors is not to be less than 3, nor more than 7; the subscribers are to appoint the first, and are to act *ad interim*; qualification £50 in shares or stock; the remuneration of the board will be £50 per annum, and such further sum as may be determined by the company in general meeting.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—This is a reconstruction of the Kensington Court Electric Lighting Company (Limited), upon the basis of an agreement of the 23rd ult., between Granville Richard Ryder and Douglas Eyre. It was registered on the 29th ult., with a capital of £250,000, in £5 shares. The subscribers are:—

	Shares.
E. W. Cox, 1, Gayton-crescent, Hampstead	1
W. Eacott, 9, Gore-road, South Hackney	1
Samuel Jordan, 36, Gertrude-street, Fulham-road	1
H. Gibson, 4, St. Mary-axe, solicitor	1
E. W. Loyd, Lancaster-road, Upper Norwood	1
G. Hamlin, 43, Somerleyton-road, S.W.	1
B. W. B. Ulph, 1, Findon-road, Uxbridge-road	1

The number of directors is not to be less than three nor more than nine; the first are G. R. Ryder, A. Sohier Bolton, Sir Charles Grant, and Roger William Wallace; qualification, £100 in shares; the company in general meeting will determine remuneration.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 6th, 1888, amounted to £4,503.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of March was 4,919, estimated to produce £3,800, against 4,775 messages, producing £3,727 in the corresponding month of last year. The traffic receipts for the month of December, estimated at £3,300, realised £3,373.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—This company announce the numbers of 276 Five per Cent. Australian Government Subsidy Debentures, which have been drawn for payment on 1st July next, full particulars of which will be found in our advertising columns. The traffic receipts of this company for the month of March, 1888, amounted to £39,670, and to £38,177 in the corresponding period of 1887, showing an increase of £1,493.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of March, 1888, amounted to £54,376, and to £49,797 in the corresponding period of 1887.

GREAT NORTHERN TELEGRAPH COMPANY.—This company announces the opening of new stations in China on the Island of Formosa at Taiwan, Takow, and Anping. The rate from all places in the United Kingdom is 8s. 9d. per word. The latest traffic returns of this company are as follows:—Receipts in March, 1888, £22,000; from January 1st to March 31st, 1888, £63,800; corresponding months, 1887 and 1886, £61,200 and £58,680 respectively.

INDO EUROPEAN TELEGRAPH COMPANY.—The directors, after adding £10,000 to the reserve fund, recommend a dividend for the six months ended the 31st December, 1887, of 17s. 6d. per share, making with the interim dividend already paid 6 per cent. for the year and a bonus of 20s. per share, making in all 10 per cent. for the year, carrying over £2,694. A year ago the distribution was the same and £1,093 was carried forward.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The directors of this company, after placing £15,000 to the renewal fund, and £10,000 to the debenture redemption fund, have decided to recommend at the forthcoming meeting of the company that a dividend of 9s. per share (free of income-tax) be paid. This, with the interim dividend already paid in October last, makes a total distribution for the past year of 4½ per cent. per annum, as compared with 3½ for the year 1886. The traffic receipts of this company for the week ended April 6th, 1888, after deducting the "fifth" of the gross receipts payable to the London-Platino-Brazilian Telegraph Company (Limited), were £3,554.

REMOVAL.—We are informed that Messrs. W. F. Dennis and Co. have removed from Leadenhall House, 101, Leadenhall-street, London, to 11, Billiter-street, London, E.C.

ELLIOTT BROTHERS,

101 & 102, ST. MARTIN'S LANE, LONDON, W.C.

TELEGRAPH ENGINEERS AND MANUFACTURERS OF ALL KINDS OF ELECTRICAL TESTING AND TELEGRAPH INSTRUMENTS.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 518.—Vol. XX. FRIDAY, APRIL 20, 1888. Price 4d.

NOTES.

The action brought by the Edison-Swan Company against the makers of the "Victoria" lamp is based upon the same two patents as formed the subject of a suit brought by the present plaintiffs against Messrs. Woodhouse and Rawson two years ago, and also since that time against Shippey Brothers. The two patents in question are :—(1) of Edison, No. 4,576, of November, 1879; and (2) of Cheesborough (the agent for Sawyer-Man in this country), No. 4,847, of November, 1878. The defendants in this action, though nominally William Holland and the Jablochkoff Company, are actually the Anglo-American Brush Corporation. The names of the former merely appear as clients and users of the Brush Company's Victoria incandescent lamps, selected for the purpose of a test-action to determine the right of the Edison-Swan Company to restrain all users of the incandescent lamps in this country (upon the strength of the judgments already delivered in favour of the Edison-Swan Company) from using any other than lamps manufactured by the latter company.

It will no doubt be remembered that in the Woodhouse and Rawson case judgment was given for the plaintiffs for both patents by Mr. Justice Butt; on appeal, the decision of Mr. Justice Butt was upheld on both patents, the three judges being unanimous in the view taken of the Cheesborough Patent; Lord Justice Cotton, however, putting a different construction to that of his brother Lords Justices, Bowen and Fry, in respect of the Edison Patent. As regards the latter, the whole issue resolves itself into the use, by Edison, of the term and claim for "filament." Singularly enough, this is the first occasion on record of the word "filament" being used to denote the illuminating portion of an incandescent lamp, and this fact affords a subtle but none the less powerful weapon when ably handled by brilliant counsel and skilful scientific experts. Edison, after describing various processes of manufacture of what are indifferently referred to in the body of the specification as "wires," "sheets," "strips," and "filaments," concludes by making four claims. The last two are claims of detail, and are of no importance for the purposes of the present action, so that the fight virtually centres round the first two, and more particularly the *second* claim, which is for the "combination of a carbon filament within a receiver entirely of glass, through which the leading wires pass, and from which the air is exhausted." The point upon which the Court of Appeal in the Woodhouse and Rawson action differed, was as to whether this claim should be construed to signify "a carbon filament" however made, or "a carbon filament" made as described in the body of the specification. The majority of the Court, however, put the former construction upon the claim, and it is this construction which in a great measure is being argued in the action now proceeding. The expression "filament" is a kind of *lusus naturæ*, to define and set bounds to which has taxed the ingenuity of the four judges who have up to the present endeavoured to cope with it. At one moment it is something which is "resilient," and "elastic," and "flexible;" at another something wherein the ratio of length to diameter is something considerable; at one time it is to possess the essential feature of "high resistance;" at another it is that which is "formed into filamentous form before carbonisation;" and finally it is "that which has succeeded where previous attempts have failed." In the present action all these characteristics and a great many more are being exhaustively discussed, and if the accumulated talent of the Bar, and of the the electrical, chemical, and physical worlds can assign boundary lines to this hitherto indefinable quantity, some such result may be looked for as the outcome of the present action.

As regards the Cheesborough Patent the position is less complicated. The patent is one for the process known as "flashing" among incandescent lamp manufacturers, and is alleged to cover the process of electrically heating in hydrocarbon gas to produce uniformity of resistance and candle-power among incandescent lamps. In this case the issue is not of primary importance, for under the improved knowledge existing at the present day as to various processes in manufacture, "flashing," though a convenience and largely resorted to, is not indispensable.

The surveyor of the Chelsea Vestry considers himself entitled to be highly amused because ten different electric lighting companies have given him ten different estimates avowedly based upon as many different constructions of his "specification" for the lighting of the Chelsea Vestry Hall. But since the "specification" specified nothing whatever except the number of lamps required we do not think that the surveyor is legitimately entitled to indulge in sarcastic observations at a result which was simply inevitable. An expenditure of only a small part of the trouble which he has since taken in "standardising" the estimates would have enabled him to draw up a general statement as to what was and what

Digitized by Google

was not expected to be included in the tender. Such a general statement need not necessarily be of a technical character, but it would, doubtless, have saved much time and trouble in preparing the estimates. On the other hand, the surveyor would probably have found the results not only less funny, but less instructive also. Surveyors are, as a rule, shrewd men, and this is a point which is not always absent from their consideration.

In these Chelsea estimates there is one fact which will certainly awaken some curiosity. Out of the ten estimates eight are for isolated installations; of these eight seven either provide for or recommend the use of secondary batteries. The remaining tender, from which batteries are excluded, came from a firm who are supposed to know more about the subject than any other private firm in the country. We are, however, informed that the firm in question were under the impression that batteries were not to be tendered for.

Apropos of secondary batteries, we are sorry to have to report—upon unimpeachable authority—that at an installation which has been described (we believe correctly) as the largest isolated plant worked with accumulators in this country, the batteries proved so unsatisfactory that their use has for some time past been entirely abandoned. The secretary of the institution in question, in reply to a letter of inquiry, writes as follows:—"We have abandoned them [the batteries] for our office illumination for some time. We now run the lights direct from the dynamos day and night, and find the result much more satisfactory." It is only fair to add that in this case the batteries were not supplied by the manufacturers whose names are most intimately associated with the construction of accumulators.

The St. James's and Pall Mall Electric Light Company, whose prospectus has appeared this week, may be warmly congratulated on the strikingly advantageous bargain which they have made with the eminent firm of Latimer Clark, Muirhead and Co. We gather from the prospectus that a provisional contract has been entered into, whereby the latter firm guarantees to provide "every requisite" for the installation of 10,000 lamps within an area of 450 yards radius from the central station, upon a low-tension direct-current system of distribution, at an estimated cost of £18,500. The Lighting Company anticipates that the profits to be derived from the installation will enable them to earn a dividend of 12 per cent., and we are more than half disposed to think that under the circumstances this ought easily to be done. But how Messrs. Latimer Clark, Muirhead and Co. can afford to carry out their part of the bargain we are totally at a loss to conceive. If, for instance, we compare the figures given by Mr. Crompton for a plant of the same output (*Electrician*, April 13th, p. 636), upon either the alternate-current or the battery system, it will be seen that the estimate for the equipment of the generating station alone with dynamos and engines considerably exceeds the figure above mentioned. Assuming that the direct-current plant costs about the same as the alternating-current central-station plant—and it is difficult to see where any considerable unbalanced economy comes in on either side—the estimate would amount to no less than £29,000 for the station alone, without taking the conductors into consideration. It should, moreover, be remarked that Mr. Crompton obtains his figures by revising the work of an earlier writer, and knocking several thousand pounds off the original estimate. If, therefore, the St. James's and Pall Mall Company can actually get the work efficiently carried out at £1. 16s. per lamp, we think that they will have abundant cause to be thankful.

Some correspondence has recently appeared in the *St. James's Gazette*, complaining of "The superfluity of educated persons" in France and in Austria. Similar complaints are of long standing in respect to Germany. In Austria, we are told, "every boy who shows any aptitude at school considers that a university career is the only one for which he is fitted." If he acts upon his convictions and attains to the grade of "Privat-docens," he usually finds that he cannot earn even the smallest pittance; and mention is made of one who, although sometime lecturer at the Technical College and the ablest mathematician of his year, was forced to become a ticket clerk on a railway. It does not surprise us, therefore, to learn that this glut of educated labour is attended with extreme scarcity of skilful artisans—those who would have become intelligent artisans being now "learned men out of work." For practical purposes, a superfluity of *un*educated persons might be preferable, and certainly would be less pitiful.

On this subject a note of warning comes to us also from America, where, it appears, numbers of English electrical students are arriving possessed of a good deal of learning, very little money, and no handicraft. The *Electrical Engineer* of New York strongly advises any who may be tempted to follow this example not to do so, lest a worse fate befal them than they have to face by remaining in their own country. Whatever the young man's educational attainments may be, one thing is absolutely essential to his candidature for a situation in the States, namely, that he "must know how to do work with his own hands, and skilfully at that, or he will find there is no room for him in an American establishment." The moral of all this is that it is high time the world's educational machinery were directed to the useful purpose of teaching people to *do* something, instead of to the superfluous task of multiplying those who can offer an opinion as to how *other* people ought to do it. Our contemporary's remarks on this subject will be found further on.

A Glasgow correspondent sends us the following extract from a local journal. As a specimen of newspaper science it would be hard to beat:—"Voltaic electricity is not intense enough for motive power; frictional, though really less powerful in proportion to means used in production, is more concentrated, hence its adoption for driving machinery, while the other, having more body if less 'go,' is used for transmission of messages over wires thousands of miles long."

The report of the Committee of Investigation appointed by the shareholders of the Pilsen-Joel Electric Lighting Company

Digitized by Google

is one of the most astounding documents which even the chequered history of electric lighting has hitherto produced. Until the directors have been heard in their own defence it would certainly be unfair to assume that some of the more remarkable features of this indictment are not capable of explanation; we therefore postpone for the present any comment upon the financial aspects of the case, referring our readers for details to the report itself, which will be found in another page. Meanwhile, however, it is difficult to see how the directors are to escape censure for the extraordinary laxity with which the details of their administration seem to have been characterised. It may or may not have been justifiable to value Pilsen arc lamps in stock at 5s. 9d. apiece (the list price being £12, and scrap value of the metal 5s. 2d.), but it is certainly wrong to allow a central station to run short of coal because the secretary is away for the Easter holidays. The loan of £2,100 to a private firm at 1¼ per cent. per annum may possibly turn out to have been effected under such special circumstances as would render it a sound commercial transaction; but we cannot admit the wisdom, under any conceivable conditions, of running a central station, *en permanence*, without a single boiler in reserve. However, the shareholders seem fairly entitled to the consolation of believing that the financial position of the company either is, or could easily be made, somewhat more satisfactory than appeared from the recent balance-sheet.

ONE sentence in this report strikes us as peculiarly worthy of attention; it sums up in few words the whole duty of the directors (of a patent-owning company); it should be printed in illuminated letters and hung in every board room throughout the land. These are the words of wisdom:—"Under good management the value of the goodwill of the business should increase in at least the same ratio as that of the diminution of the value of the patents." This may not always be an attainable ideal, but whensoever realised it may surely be taken as *primâ facie* evidence that sound, shrewd, and honest dealings have characterised the conduct of that company. But where, alas! amongst the purveyors of electric light shall we find the limited liability concern whose directors are prepared to submit their work to such a test as this?

How little reliance can be placed on the advice of financial organs is shown in the fact that one of them, which was foremost in "bulling" the telephone stock on the strength of the Postmaster-General's speech at Wolverhampton, is now chuckling at the discomfiture of buyers in consequence of his speech in London last Friday. The first effect of this latest deliverance was to send down telephone stock rather heavily. It has since, however, almost recovered the shock, partly because it is believed that the companies can work their property in the next three years so as greatly to enhance its value; but largely, no doubt, because a State purchase in any case is always confidently expected to be advantageous to the vendor. It may be so, and we trust it will; but the opinion of financial newspapers on this point is to be received with much caution.

IN reviewing a certain work not long ago we said that the "first half of the book was fairly good and practical all through,' but proceeded to show that the second half was very much otherwise. The publishers appear to have taken the same view of our criticism, and are now using the first half of it for advertising purposes as follows:—

"Practical and good all through.—*Electrician.*"

Capital Punishment by Electricity.—The New York Assembly has passed a Bill substituting death by electricity for hanging in capital cases, by 87 votes to 8.

London, Brighton and South Coast Railway's Electric Lights.—The London and Brighton Railway Company have now fifteen trains lighted by electricity, two running between London and Brighton, and thirteen local trains.

Spanish Tenders for Telephone Service.—The Madrid *Gazette* of Saturday last contains a Royal order for tenders to be invited for the establishment and working of a telephone service in the manufacturing town of Sabadell (Barcelona).

Tenders Required for Supplying Lighting Plant.—We would direct the attention of those interested to the notice in another column of the House-to-House Company, who are asking for tenders for the supply of engines and dynamos for a central station at Kensington.

Glasgow.—The contract for the electric lighting of the New Municipal Buildings in this city which have been in course of erection for several years, has been let to Messrs. Muir, Mavor and Coulson, who will supply the current from their central station, from which also they supply the lighting current for the Glasgow General Post Office.

Royal Meteorological Society.—The usual monthly meeting of this Society was held on Wednesday evening, the 18th inst., at the Institution of Civil Engineers, 25, Great George-street, Westminster, Dr. W. Marcet, F.R.S., president, in the chair. Amongst other Papers, one on "Lightning in Snowstorms" was read by Prof. A. S. Herschel, F.R.S.

The Brussels Exhibition.—We have received from M. Bandsept, who is the electrical engineer in charge of the lighting of this Exhibition, a detailed plan showing the number and position of the lights which are to be employed. So far as it is possible to judge from this plan, it would seem that the arrangements will be of a highly efficient character.

Forthcoming Works.—Dr. William Pole is making progress with his "Life of Sir William Siemens." A selection of Sir William Siemens' scientific papers is also in the press. Prof. Tyndall has been at work on a new edition of his "Researches on Diamagnetism and Magne-Crystallic Action, including the Question of Diamagnetic Polarity." The volume in its revised form will be issued by Messrs. Longmans in a few days.

Electrolytic Reduction of Zinc Ores.—Referring to a recent note in this journal on Mr. Watt's process for the reduction of zinc ores by electrolysis, *L'Electricité* says that the same thing has been done for some years past at Saint-Denis, but that they have been unable to obtain any information as to the exact method which is followed. It is also said that successful experiments of the same kind have been made at the works of MM. Sautter et Lemonnier at Paris.

The "Otto" Gas Engine.—Messrs. Crossley Bros. have issued a new catalogue of their well-known "Otto" gas engine. This list will be found of special interest to electricians, and it describes several types of intermediate size to those hitherto built. The 20 horse-power engine has met with a large demand of late for isolated electric lighting plant. Messrs

Digitized by Google

Crossley Bros. are also making a special feature of their combination plants, such as engine and pumps, engine and dynamo, engine and hoists, &c.

Sheffield.—At the last meeting of the Sheffield Town Council the Town Clerk read a letter from Messrs. John Tasker and Co. asking the Council to adopt the electric light in the leading thoroughfares of the town, and saying they would be pleased to do it without much profit as an introduction. The Town Clerk thought that in view of the Local Government Bill giving enlarged powers to the town, the Council would hardly sanction any such arrangement as that suggested at present. On the motion of Mr. F. P. Rawson the communication was referred to the Watch Committee.

Cables for Alternating Currents.—The Grosvenor Gallery Company have recently been testing an anti-induction electric light cable, in an underground conduit, in which were also several telephone wires. The results were most satisfactory. The cable contains a 19-strand wire, well insulated; around this is a copper sheath, which is also highly insulated; the strands and the sheath form the lead and return wires. When the copper sheath was *not* used as the return there was great induction, but the telephone remained absolutely silent when the copper sheath was utilised.

Arc Lamps in Lanterns.—In connection with a Paper read by Mr. Norman Lockyer before the Royal Society on the 12th inst. a small "Brockie-Pell" arc lamp, taking a current of about 5½ amperes, was used for projecting the illustrations. Notwithstanding the small current used on this occasion, the experiment was a marked success, and the absolutely steady, silent light given by the lamp was greatly admired by those present who take an interest in such matters. The apparatus was supplied by Messrs. Drake and Gorham, and the current was obtained from the accumulators used for lighting the hall.

Taunton.—At a meeting of the Taunton Town Council on Tuesday it was proposed to light the whole town by electricity. A memorial signed by 700 of the inhabitants was presented in favour of the scheme. It was explained, however, by the chairman of the Finance Committee that in view of the extra expense which would be incurred by the sewage works the increased lighting could not be provided without materially adding to the rates, and this view was adopted by several members present. The proposal of the Lighting Committee to extend the electric light was ultimately defeated by eight votes to seven.

University College, Bristol.—This college reopens on 25th April. The work in the engineering department during the coming term will be largely of a special character. Prof. Ryan will lecture on Civil Engineering, Mining Engineering, and Electrical Engineering. The last-named course will comprise electric lighting, dynamo electric machinery and transmission of power. Civil engineering students will attend Prof. Lloyd Morgan's practical Geology classes in the field, and Mr. Selman's outdoor exercises in Surveying. Electrical engineers and others will occupy themselves in the chemical, physical, and engineering laboratories of the college.

The Telegraph Service.—In the House of Commons on Friday last Mr. Raikes, in answer to Mr. Handel Cossham, said he did not propose to reduce the ordinary attendance of civilian male telegraphists from 50 to 48 hours per week, or to pay them extra for work done on Sunday. Their present pay was fixed so as to include remuneration for 50 hours' work a-week, namely, 48 hours on week days and two on Sundays. In reply to Mr. A. O'Connor, Mr. Raikes said that at the present time there were over 60 vacancies in the first class of telegraphists at the Central Telegraph Office, 40 of which were due to an augumentation of the establishment since the estimates were prepared. Promotions had recently been made, and further promotions would be made in due course during the financial year. The expenditure for salaries paid to telegraphists at the Central Telegraph Office would, he believed, approximate very closely to the estimate.

Paris Universal Exhibition, 1889.—A circular, issued from the Mansion House, states that the applications from intending exhibitors for space in the British Section of this Exhibition ought all to be sent in before the end of the present month, addressed to the Offices of the Section, 2, Walbrook, E.C. They have been asked for thus early in order that the executive council of the section may be able to form an approximate idea of the actual amount of space which they should take over from the French authorities. Applications received after the 28th inst. will not be refused; but they can only be entertained subject to the possibility of space being found for them, and the total area required for the British Section will be calculated on the amount applied for before that date. Up to the present a satisfactory number of applications have been received, and the executive council anticipate that the whole of the space which can be placed at their disposal will be fully occupied.

Communication with Lighthouses.—On the 12th inst., at the Board of Trade, Sir Michael Hicks-Beach received a deputation from the Associated Chambers of Commerce. The object of the deputation was to solicit Government aid in the establishment of national harbours of refuge, the abolition of light dues, and improved communication with lighthouses.—Sir Michael Hicks-Beach, in replying, said he had understood that the important question they intended to bring before him was the question of the effect of communication with lighthouses, lightships, and telegraph stations. He found that the United States, at any rate, had no such communication. In Germany there were only three places in communication, and there was no communication with lightships. Still, he did not mean to say that this precluded them from taking measures in this direction. He knew of no instance of telegraph communication having led to the saving of life or property. Attention had been called to the acquisition by Lloyd's of signalling stations. They had not heard of this proposal this year, or he would be disposed to look upon it favourably. He certainly believed there was a great danger as to life and property through the present difficulty of obtaining sites for stations.

Thermal Variation in Daniell Cells and Accumulators.—The February number of *Wiedemann's Annalen* contains a paper on this subject by G. Meyer. The author finds that the E.M.F. of a Daniell (H_2SO_4) cell increases with the temperature. The temperature-coefficient, E.M.F./temperature, depends on the degree of concentration of the fluids in the cell, increasing as the solution of H_2SO_4 becomes more concentrated, until the solution attains a strength of 30 per cent., when it reaches a maximum, and diminishes when the acid solution becomes still further concentrated. The temperature-coefficient increases steadily as the concentration of the $CuSO_4$ solution increases. In the case of the $ZnSO_4$ cell, the E.M F. falls as the temperature rises, and the result of diluting the $ZnSO_4$ solution is that the temperature-coefficient, which is negative for a moderately concentrated solution, passes through zero, and attains a positive value. Increasing the concentration of the $CuSO_4$ solution has the same effect as in the case of the ordinary H_2SO_4 cell. With regard to accumulators, the author finds that there is no perceptible change in the E.M.F. when the temperature is varied. The method of measurement adopted did not enable him to deter-

Digitized by Google

mine whether the E.M.F. varies with the concentration of the acids, owing to the complication introduced by the fact that as soon as the charging current ceases the E.M.F. begins to fall rapidly at first and afterwards much more slowly. Streintz and Aulinger have shown that this is due to oxidisation of the lead plates.

St. James's Vestry and the Electric Light.—At the last meeting of the St. James's Vestry the Lighting Committee recommended that the consent of the Vestry be given to the St. James's and Pall-mall Electric Lighting Company applying to the Board of Trade for a licence under the Electric Lighting Act, 1882, subject to the company agreeing to the modifications made by the committee in the draft licence, and to any alterations being made in the clauses relating to technical questions which the Board of Trade may require. Mr. Winnett hoped the Vestry would pause before adopting this recommendation. Again and again electric lighting companies had tried to get possession of the area which this company also desired to be compelled to light. Why was it that this part of the parish of St. James was always so much coveted by these companies? Because it was the most valuable for electric lighting of any district in London. When the companies were asked to include other parts of the parish under the compulsory clauses they always politely but firmly declined. The Vestry had received very short notice of this matter, and it behoved them to inquire closely into the constitution of the company before handing over to it a valuable district with the exclusion of others. It was all very well for a company to propose to light this district; it was quite another thing to do it. One company which had applied to that Board had spent a hundred thousand pounds on the endeavour to make this kind of electric lighting supply a commercial success. Yet they had failed. What probability was there that this new company would be more successful? He trusted the Vestry would at least take more time to consider the proposal. Mr. Tapping took the same view as Mr. Winnett. Mr. W. Jenkins defended the action of the committee. Mr. Dixey moved, and Mr. Osborn seconded, that the matter be referred to a committee of the whole Vestry for further consideration. This was carried.

"Don't."—The following editorial appears in the current number of the *Electrical Engineer* of New York:—"The great activity prevailing in this country at the present time in the principal electrical industries is very naturally attracting the attention of many young men abroad, especially in England, who after graduating from some technological institution, and providing themselves with unexceptionable letters of introduction to some one in New York, speedily find their way across the Atlantic, in full confidence that remunerative employment awaits them immediately upon arrival. Our transatlantic contemporaries cannot do many of these young gentlemen a greater service than to pursuade them, if possible, to accept and act upon the celebrated advice of *Punch* to those about to marry. While it is true that most of these persons ultimately find employment in some capacity or other, yet not a few have been compelled to undergo experiences which are, to say the least, exceedingly humiliating to a sensitive soul. Many of them are supplied with barely more than enough money to land them in New York; they then learn, to their dismay, that almost all the electrical establishments of importance are situated at distances varying from 200 to 1,000 miles or more from the metropolis, and can only be reached by an expensive railway journey. They further find, usually to their very great astonishment, that their letters of introduction and of recommendation, so indispensable in Europe, are of little more account on this side of the ocean than so much waste paper. A man in this country always expects to apply for a situation on his own merits. 'Influence' goes for little or nothing. If an employer happen to have a vacancy, and the applicant appear to be capable of filling it, he is likely to have a chance to try, even though he may be an utter stranger. If he were backed by a personal letter from the President of the United States it would, as a rule, make very little difference. One thing is absolutely essential—the candidate must know how to do work with his own hands, and skilfully at that, or he will find there is no room for him in an American establishment. We do not say this to discourage our English cousins, for we are well aware that many of the most successful electrical engineers in America have come here as young men from across the seas. But it will save much disappointment if those who may come hereafter start with a definite conception of the industrial conditions and customs of this country, which differ so widely in many respects from those to which they have been accutomed at home."

An Early Inventor in Electric Lighting.—The Rev. G. H. Staite, vicar of Sutton Cheney, Hinckley, writes to the *Pall Mall Gazette* as follows:—"Knowing your love of fair play and readiness to ventilate hidden grievances, I venture to ask the insertion of this letter, in the belief that if the facts were known some among your many readers would be inclined to entertain the claims of the family of a man who spent his life and fortune on a recognised public work of the greatest importance. My father was the originator of electric lighting, his exhibitions extending from 1847 to shortly before his death in 1854. During that interval he expended a considerable fortune, and left his family penniless. There are at the present time his widow, aged eighty, two daughters, and myself. That our claims to recognition are not unfounded will be seen from the following testimony:—Prof. Tyndall—'Fragments of Science,' Vol. II., p. 424: 'To keep the carbons at the proper distance as under regulators were devised, the earliest, I believe, by Staite.' 'Haydn's Dictionary of Dates,' later editions, 'Electric Light:' 'Apparatus for regulating the electric light were devised in 1846 and shown by Staite and Petrie in 1848.' Urquhart, 'Electric Light:' edited by Webb, 1880, p. 161: 'Staite and Edwards patented an electric regulator based upon the heating and expansion of metals by the current to be regulated. This idea, beautiful in tself, is really the original of the regulators used to-day, and the self-same principle is employed by Mr. Edison.' And 'Dr. Siemens,' page 173: 'Staite as early as 1847 patented a lamp in which the lower carbon is controlled by a movable soft iron core acted on by a hollow electro-magnet.' Fontaine and Du Moncel gave similar testimony. The priority of the principle of automatic regulation, the *sine quâ non* of electric lighting, was decided in my father's favour by the French Academy of Sciences, as recorded in *Le Courrier Français*, February 4, 1849. Of his many patents and improvements no use could be made by his family; practically, as far as they were concerned, they died with my father, although they were and are still available for subsequent workers in the same field. His family feel that they have entirely lost their fortune through his public enterprise. All their money, consisting of thousands of pounds, was sunk, and by the premature death of the inventor in his forty-second year his and their hopes of any pecuniary return were irretrievably lost. It is this combination of facts which induces me to write this appeal, every point of which I shall be most glad to substantiate should any one be kindly induced to notice it."

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

(*Continued from page 593.*)

The next subject which claims attention is the method of experimentally measuring the *power* taken up in inductive circuits traversed by periodic currents. There are amongst others two instruments especially useful for measuring periodic currents. One of these, the Cardew voltmeter, depends upon the principle that when a wire traversed by a current either steady and unidirectional or steadily periodic is placed in an enclosure, the walls of which are approximately at a constant temperature, the wire will itself after a short time attain a constant temperature. This constant temperature is reached when there is a state of equilibrium between the rate at which heat is radiated by the wire and the rate at which the walls of the enclosure radiate heat back to it.

The wire has a definite length corresponding to each temperature, and means are provided for measuring this elongation with great accuracy. The total amount of heat generated in the wire per second is dependent upon the rate of generation at each instant. This instantaneous rate of heat development is by Joules's law equal in mechanical units to the product of the ohmic resistance and the square of the instantaneous current strength.

If the wire is traversed by a simple periodic current, and we construct from the current curve diagram another curve, whose ordinates are equal to the square of the corresponding current ordinates, we have a curve every ordinate of which is proportional to the instantaneous rate of generation of heat in a wire traversed by the periodic current. Since the horizontal line measures time, it is obvious that the whole area of the outer curve, or heat curve, represents the total work done per semi-period by the current in producing heat, and that the same total work would be done by a steady current whose value was the square root of the mean of the squares of all the ordinates of the periodic current curve.

This square root of the mean of the squares of all the ordinates of a simple periodic curve has, however, been shown on p. 284 to be numerically equal to the value of the maximum ordinate of the periodic curve divided by $\sqrt{2}$. It follows that the total heat generated per second in the wire is a numerical measure of the half the square of the maximum value of a simple periodic current. A fine wire stretched out in the manner of a Cardew voltmeter wire has a very small inductance, and hence, when acted upon by a simple periodic electromotive force, the current produced in it is very nearly proportional to this impressed electromotive force. It follows then that when a Cardew voltmeter is subjected to a simple periodic E.M.F. the needle takes a definite position, corresponding to a definite expansion of the wire, which is that which it would take if the wire were subjected to a steady electromotive force equal to $\frac{1}{\sqrt{2}}$ of the maximum value of the periodic electromotive force.

The Cardew voltmeter is not adapted to measure any but very small currents. The instrument generally employed to measure periodic currents of moderate and large magnitude is some modification of Weber's electro-dynamometer. In the best-known practical form of Siemens there are two coils of wires in series, one fixed and the other movable, and so placed that the currents in the movable coil circuit are traversed at right angles by the lines of force due to those in the fixed coil. When a simple periodic current traverses the coils in series, a force is brought into existence due to the electro-dynamic action, and which is proportional to the instantaneous value of the square of the current strength. From instant to instant, however, the current strength varies. If the time of free vibration of the moveable coil is very large compared with that of a complete period of the electrical vibrations, and if the movable coil is brought back by a restoring force due to a spring or bifilar suspension or gravity, &c., into a fixed normal position, then, during one complete electrical period, we may consider that the movable portion receives a number of small impulses which are in magnitude represented by the square of the ordinates of the current wave. Hence, the total impulse on the movable coil is equal to the magnitude of the integrated area of a wave curve whose ordinates are respectively the squares of those of the current curve, and the mean force on the movable coil will obviously be proportional to the mean ordinate of this force curve. If the movable coil is so heavy that its time of free vibration is very long compared with the time in which the periodic forces on it run through a complete cycle, it will experience a displacement exactly that due to the mean of the forces acting upon it—that is, to the square root of the mean of the squares of these instantaneous currents—or to $\frac{I}{\sqrt{2}}$, where I is the maximum value of the current during the period. The periodic force on the movable coil is equivalent to a steady force, when this periodic force runs through all its values in a time very short compared with the time of free vibration of the coil. Hence, if a simple periodic current has a maximum value I, when it is sent through an electro-dynaommeter it will cause a deflection equal to that which would be caused by a steady current equal to $\frac{I}{\sqrt{2}}$.

Let us suppose a coil of constant inductance L and resistance R to be traversed by a simple periodic current of frequency n (where $2\pi n = p$). Let an electrodynamometer be inserted in series with it, and let a Cardew voltmeter be connected to the extremities of the inductive circuit. Under these circumstances many persons have and do suppose that the product of the readings of the voltmeter and dynamometer gives the *power* taken up in the induction circuit. From what has gone before we now see that this cannot be the case, for even *assuming for the moment* that the Cardew voltmeter gives a reading indicating truly the square root of mean of the squares of the periodic potential differences between the two points to which it is connected, the product of Cardew reading and the dynamometer reading does not give the power, since it takes no account of the difference of phase of the current and impressed E.M.F.

We have above seen that if E and I are the maximum values during the period of the impressed E.M.F. and current in an inductive circuit, then the *power* taken up in that circuit is equal to $\frac{EI}{2}\cos\theta$, when θ = angle of lag of current behind the E.M.F. But the reading of the Cardew voltmeter when connected to the ends of an inductive circuit is very nearly proportional to $\frac{E}{\sqrt{2}}$, and the dynamometer reading in that circuit is proportional to $\frac{I}{\sqrt{2}}$; therefore, the product of these readings is proportional to $\frac{EI}{2}$, and takes no account of the difference of phase. For this reason we can derive no information from the use, in this manner, of these instruments. A very small error, in practice negligible, is introduced by disregarding the inductance of the wire of the Cardew instrument. On this account strictly speaking currents in the wire cannot be taken as accurately proportional to potential differences at the extremities, but this is in ordinary usage a neglectable error.

(*To be continued.*)

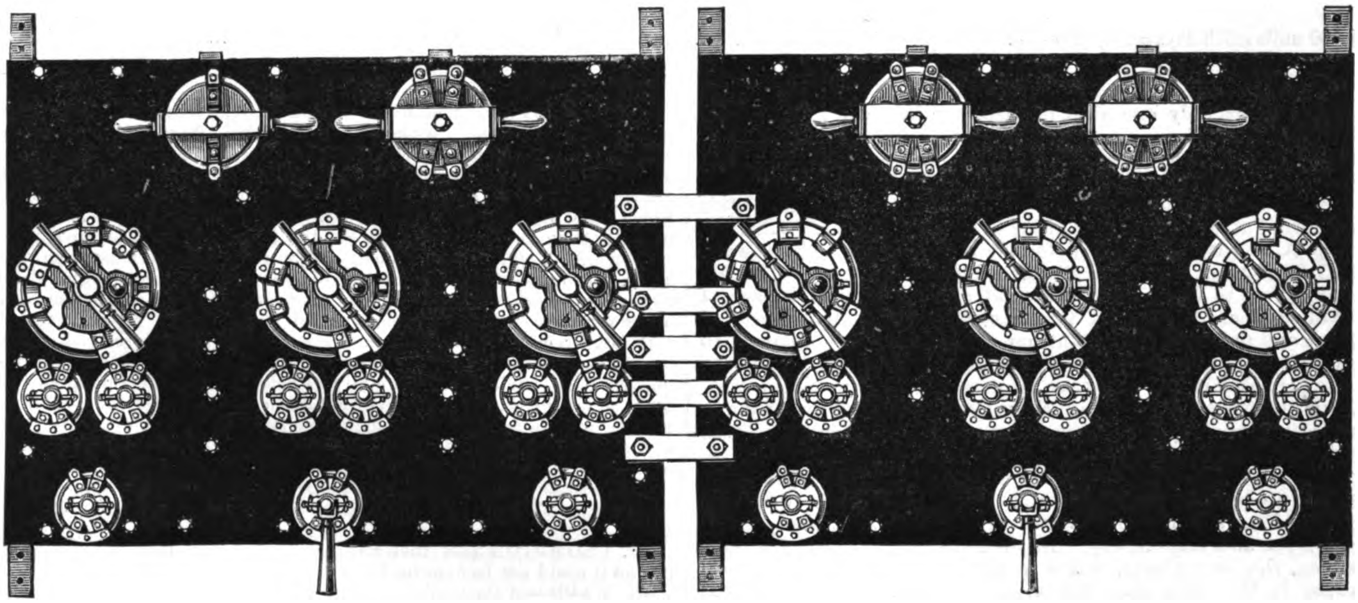
LARGE SWITCH-BOARDS FOR DISTRIBUTION WORK.

We have recently had the pleasure of examining a very large switch-board which the United Electrical Engineering Company (Limited) have constructed to the order of the Aluminium Syndicate, who are introducing the process of Dr. Kleiner, by which the direct electrolytic reduction of the metal from fused cryolite is effected. The switch-board has been built, under the direction of Mr. Nevile, to distribute the current from a group of four dynamos. One of these four machines is of

Digitized by Google

higher E.M.F. than the others, and is used for starting the operation upon any one of the eighteen separate crucibles which the switch-board is intended to control. At a certain point in the process, when the cryolite has become fused, a lower E.M.F. is sufficient to carry on the reduction.

The switches are mounted upon a slab of slate measuring 11ft. in length by 4ft. in height, and raised 5in. from the wall by means of side battens. The large switches seen at the top are one double-break on and off switch for the high-tension dynamo, to carry 500 amperes, and three two-way switches for 1,000 amperes each. The six crucible switches below are of special design, and are constructed to transfer a crucible from the high-tension to one of the low-tension dynamos, at the same time connecting the high-tension dynamo to a resistance, and removing a resistance from the low-tension dynamo, the object being to keep the load upon the engine gearing and dynamos approximately constant. The 18 lower switches are close-contact two-way switches, each controlling one crucible and allowing the current to each crucible to proceed to it either direct from the dynamo or by way of one of the above special switches. By this arrangement 18 or more crucibles can be controlled six at a time by means of the special switches. Provision is also made for an addition either to the number of dynamos in use or to the number of crucibles operated by each machine. The switches, which are of very substantial make, are furnished throughout with Drake and Gorham's adjustable ring contacts, and all of them are of the double break type. The whole of the details have been carried out in a manner which reflects the highest credit upon the United Electrical Engineering Company.



Large Switchboard for Distribution Work constructed by the United Electrical Engineering Company.

CENTRAL STATION LIGHTING.—TRANSFORMERS v. ACCUMULATORS.*

BY R. E. CROMPTON.

(Concluded from page 637.)

Comparison of Working Cost and Maintenance; Coal Bill of the A.T. System.—The generating plant on the A.T. system has to run continuously—that is to say, that the larger engines will be run for an average of three hours per day, and if it be found practically possible to subdivide the plant into a number of engines, and work them parallel, as is the case with the direct-current system, we may be able to credit the engines and dynamos with an efficiency of 75 per cent. during these hours. In order to meet the average demand of 2,100 units per day, the load diagrams show that they will vary during these hours from 400 to 720 kilowatts. We have as yet been furnished with no actual data as to the actual efficiency of the alternating-transformer system at various rates of output—that is, the E.H.P. actually delivered to the lamps, divided by the E.H.P. at the terminals of the dynamos. It must be recollected that, as the transformers must be large enough to supply the maximum demand of each house, whereas the maximum demand that the station can supply is probably not more than one-third of this, the transformers during this period of three hours cannot be more than one-third loaded, and therefore it is not probable that their efficiency is more than 70 per cent. It follows that, during the hours when the plant is working at 500, 400, and 300 kilowatts, the total efficiency—that is, E.H.P. delivered at the lamps, divided by the I.H.P. in the engine cylinders, including loss in mains, will not be above 54 per cent. Supposing that the steam engines can work at 2½lb. of coal per I.H.P., the net quantity required per E.H.P. will be 4·65lb., or 6·21b. per kilowatt. The output during these hours may be considered as 60 per cent. of that of the whole day, or, say, 1,260 kilowatts, therefore about 70cwt. will be used during these three hours. During the remainder of the 21 hours the transformers will be working at a very small rate of output. It is probable that their efficiency will be reduced to 30 per cent., and the efficiency of the steam engines and dynamos to 50 per cent., or a total efficiency—that is, E.H.P. at the lamps, divided by the I.H.P. of the engines—of 15 per cent. only; therefore, during this period it seems probable that 17lb. of coal will be used per E. H.P. or 22·5 per kilowatt. Therefore, the coal used in producing the balance of the daily output of 840 kilowatts will be about eight tons eight cwt., or, making a small allowance for the lighting up of boilers, 12 tons per day. The oil, water, and petty stores may be calculated at 7s. 6d. per hour for three hours during the day, and at 1s. per hour during the remainder of the time. Therefore, the total cost of material used in running this station will be £4,849. The B.T. system, on the other hand, will show great saving on this. For the output of 2,100 units, it will be sufficient to work the generating plant for about five hours at approximately its greatest rate of efficiency. I have had ample experience with this class of plant, and know that we can in actual practice produce the E.H.P. at the terminals of the dynamo with the expenditure of 3½lb. of coal. Taking the maximum loss in the accumulators, the efficiency of the system—that is, the E.H.P. at the lamps—divided by E.H.P. at the terminals of the dynamo, will not be less than 80 per cent.; therefore, we may say that each unit at the lamps can be produced for 5·75lb. of coal, or five tons eight cwt. per day, or allowing a 25 per cent. margin for contingencies, 2,550 tons per annum. The water and petty stores may in this case be taken at 5s. an hour for 1,400 hours; the total cost of the material for producing 2,100 units by the B.T. system will be £2,517, or only about 57 per cent. of the cost of material by the A.T. system. *Turning now to the labour in the engine room,* the table before you shows that, as in the case of the A.T. system, the hours are continuous, three shifts of men will be required, it is necessary to have two foremen, six engine drivers, and nine firemen, whereas in the B.T

		4,683 5 0		4,086 10 0
		11,939 13 0		8,598 10 0
2,100 units × 365 days = 766,500 units. Cost per unit		3·75d.	...	2·7d.

system there is only one shift of men, one foreman, four drivers, and three firemen are employed. I have only estimated for two extra men in the engine room for the A.T. system, but for the B.T. system I have allowed for four accumulator foremen in charge of the four accumulator stations, and two messengers. The totals thus arrived at for labour for working the systems are £1,389. 8s. 8d. for the A.T. system, and £975 for the B.T. system. The salaries are £1,220 for the A.T., and £1,020 for the B.T. system. The last item we come to is one for *repairs and renewals*. In both cases I have allowed at the rate of 10 per cent. on the motive power of engines and dynamos, 5 per cent. on the buildings and fittings, 10 per cent. on transformers, 15 per cent. on accumulators, 7½ per cent on the insulated mains that have to carry 2,000 volts, 2½ per cent. only on the bare copper mains, the majority of which only have to carry 110 volts, 10 per cent. on all regulating appliances. Thus, nearly the heaviest item, the *maintenance*, comes to £4,683. 5s. in the A.T. system, and £4,086. 10s. for the B.T. system. The gross cost of producing 776,500 units by the A.T. system would be £11,939. 13s., and the B.T. system would be £8,598. 10s., or 3·75 and 2·7 per unit respectively. In order to make a fair comparison between the two plants, when worked in the most economical manner, if the generating station of the B.T. system is worked longer hours it can actually produce the daily average of 3,600 units named by the writer in *Industries*, and in order to do this the sole increase in the working expenses would be in the materials, to which £1,800 would have to be added. The cost then, of 1,314,000 units, would be £10,398. 10s., or 1·9 per unit by the B.T. system.

It will be seen, therefore, that while by both systems there is a probability of a fair return on the capital expenditure, yet in almost every respect the B.T. system is a more economical one. This arises from the fact that the main cause of expense in the A.T. system, depending, as it does, on continually moving machinery, is the heavy cost of material, labour and superintendence during the long hours in which the machinery is working very lightly loaded. The B.T. system shows very favourably in this respect, as even at the latter increased output of 3,600 units per day the machinery need not work on the average more than ten hours, so that one shift of men can do the work, and there is ample time for repairs and inspection of machinery.

———

DISCUSSION. THURSDAY, APRIL 12.

Mr. KAPP thought that if the makers of batteries had searched from one end of England to another they could not have found a better advocate than Mr. Crompton, because he thoroughly believed in accumulators. Even when some years ago the Victoria installation was planned, he intended to use them, but they had not been put in because they were not reliable at that time. He (Mr. Kapp) was very glad to hear that they were reliable now, though it was a surprise to him. He congratulated the makers of accumulators on the paper, because it would give contractors for, and users of, the electric light more confidence in these appliances. Although he differed from Mr. Crompton, he admired the very able and plucky way in which he had fought the battle of the accumulators against the transformers. Mr. Crompton said that 3,600 units per day was too much for a plant which could supply a maximum of 600 kilowatts at the lamps. According to the London diagram it was so, but the Boston diagram showed 3,000 or even 3,600, and the Cincinnati diagram was not very far from that figure. The reason why the London diagram was smaller was that there were very few offices on, and probably not many theatres and public halls where the lights were on for many nights in the year. He quite agreed with Mr. Crompton that people had generally overlooked the fact that a conductor consisted of something more than copper. The cost of the insulation itself ought to be carefully calculated, but Mr. Crompton had gone too far the other way, having put down a higher cost for insulation and laying than necessary. A high-class lead-covered cable of half-square inch section cost about 13s. per yard, and for the double conductor £130 per 100 yards. Such a cable could be laid straight into the ground; the only protection necessary would be to cover it with rough plank and fill the trench. That would bring the cost up to a total of £155, and not £187.

Mr. CROMPTON said that £187 was what had been paid for doing it, and it could not be done for less.

Mr. KAPP said the insulation of a lead-covered cable would be reckoned by hundreds of megohms per mile, while the insulation of Mr. Crompton's mains could hardly be 1,000 ohms per mile. A Berthoud-Borel cable of 155 square millimetres costs at the present advance in copper £40, or £80 for the double main, and £105 for the main laid. Mr. Crompton's main of only a slightly larger section cost £100. There then was a saving of 5 per cent., but was it worth while for so small a saving to give up a main the insulation of which was measured by megohms, and adopt one in which it was measured by hundreds of ohms only? Of course if Mr. Crompton's system was absolutely perfect it might be worth while, but he (Mr. Kapp) would not care to be the engineer in charge, and be responsible for the maintenance of these mains. He was opposed to the plan of having a network of high-pressure mains throughout the whole district; he preferred a network of low-pressure mains, with only a few high-pressure feeders going to stated points. In that way, instead of 20,000 yards of high-pressure cable, there would be only a comparatively short system of such feeders, and along the network of distributing mains there would be a certain number of transformers—ten or twelve. Mr. Crompton took distributing mains of ¼ square inch section, and fed them from four local batteries, which were to be installed in mews as near as possible to the line of lighting; but in that case there were either too few batteries or there was too small a section of main. It was evident that the fewer the points at which the network of mains was fed the larger must be the section to be able to take the currents without serious loss of potential. Mr. Crompton had mentioned four volts as the maximum variation allowable. That was too much. He doubted whether the British householder would put up with the same variations of light as he used to do with gas. A little latitude—say, one volt—must also be allowed the imperfections of the regulating apparatus. We thus get 5 per cent. variation in pressure, and this is objectionable, because it means 10 to 15 per cent. variation in light. The speaker thought something like two or three volts should not be exceeded. It was a very difficult matter to settle what size of main was necessary in a given district. It depended

Digitized by Google

on the configuration of the place, because advantage must be taken of the carrying capacity through cross streets. It was impossible to say offhand whether a ¼in. main was enough for a 600-ampere current or not, but taking Bradford as an example, they would find by consulting the specification that about 3,000 lamps would be installed, and the whole current would have to be supplied through three feeding centres, making 1,000 lamps depending on each. The main to be used there was ·177 square inch area, and the variation permitted was two or three volts. With a main of a quarter square inch it would be possible to supply 1,400 lamps, or 4,200 from three centres. To supply 10,000 lamps continuously burning nine or ten feeding centres would be required, and in Mr. Crompton's system advantage could not be taken of the interlacing of the network, as in a simple two-conductor service. To make up for the loss of carrying capacity of cross connections Mr. Crompton would have to use more local centres, and install at least ten battery stations if he wished to retain the quarter square inch mains and not exceed the variations of pressure, which in the case of Bradford Mr. Shoolbred had limited to about two or three volts. For such a number of centres six more attendants would be required, and at £100 a year each there would be an extra £600 working cost. If Mr. Crompton wished to retain the four-battery centres, then, instead of a main of a ¼ square inch he would have to use one of 1½ square inch. That would come to about £200 per hundred yards, so that the estimate would have to be increased by £20,000. The maintenance would also have to be increased by £1,532, and it would probably be cheaper to subdivide the battery into ten local centres, and have more attendants. He wished to ask Mr. Crompton whether, in his estimate, he had included rent of rooms for the accumulators? He had told them that he could not put a drain pipe through private property, but he wanted to put on private property a whole set of batteries containing sulphuric acid. The rent would cost at least £500 annually, and the wages of the six additional men would raise the amount to £1,100 a year. But if the ¼ square inch main were adopted, and the accumulators were fed by alternate transformers, ten in number, each capable of supplying a maximum of 1,000 or 1,200 lights, the rent would be insignificant, and nothing would have to be paid for attendance. Mr. Crompton said he was ready to supply batteries at the figures he had quoted, and he (Mr. Kapp) knew there were many people who would be willing to supply 10 transformers, each of 1,000 or 1,200 lights, for £3,000, as against the estimate of £7,500. The space occupied by each transformer would not exceed about 20 cubic feet, and it would not be very difficult to find accommodation for it in a chamber lined with cast iron under the footway, or in a small fireproof room on mews property. He was rather inclined to think that the author had underestimated the cost of batteries. His authority for this statement was Mr. Crompton himself. A few months ago he asked that gentleman what in his opinion would be the cost to be allowed for batteries which should have a very rapid discharge; and from the figures then supplied he found that the cost would be £30 per kilowatt, but according to the paper it would only be £15 to £16. Was there any maker who would supply a battery giving for a short time and without being injured 10 kilowatts at £160? Mr. Crompton's comparison of the two systems as regards efficiency was very unfavourable to the alternating transformers, assuming, as he did, that a transformer one-third loaded could not have more than 70 per cent. efficiency. That was merely an assumption, for Prof. Ayrton had given them the results of some experiments with a two horse-power transformer which when working at 318 watts, or a fifth of its full output, gave 80 per cent. efficiency, while at one-third of the full output the efficiency was 85·8 per cent. It was not necessary to work transformers at less than one-third of their output. If 20 per cent. loss were allowed in the feeding mains (which would be a very economical way of working) there would then be the 20 per cent. to draw upon when the transformers were working with smaller output, so that there was a tendency for the loss in one apparatus to be balanced by the gain in the other. If they worked with a reasonably large output it would not be found so bad as Mr. Crompton made out. He wished to ask a question about the regulation. When batteries were worked in private installations 2½ volts per cell were allowed for charging and 2 volts were obtained in discharging. How could Mr. Crompton insure constancy of potential whether he was charging or discharging? As far as the speaker knew, there were two methods available. They could either couple the lighting circuit to the local centres through rheostats, which must continuously be adjusted in accordance with the demand—and this method, as they all knew, is in use in the Edison stations, but it, of course, entails a certain waste of energy—or they could change the number of cells coupled between the lighting circuit, and thus they could regulate the pressure. But, in that case, some of the cells would get charged and discharged differently from the others, and he wanted to ask Mr. Crompton how he would protect those cells from injury under this treatment?

Mr. PARKER (of Wolverhampton) said he had listened to Mr. Crompton with a great deal of pleasure, especially to his efforts to make clear the cost of the cables and various parts of installations. He was not a recent convert to batteries, and as his firm was turning out 5,000cwt. of batteries per year he had had considerable experience with them. He did not take much exception to the figures which were given in the paper as to the cost of batteries, but though Mr. Crompton alluded to Vienna he did not say what was done there. A matter of 400 or 500 volts did not appear to be a sufficient pressure to work the batteries with if a comparison was made with the other system. The effort made some years ago at Colchester seemed to have fallen out of notice. The reasons as to the failure of that installation did not seem to have been carefully studied. The first reason appeared to be the insufficiency of the number of lights attempted, and the second the mode of insulation used in the cells, which were not so good then as now. He would like to send some cells from Wolverhampton to be tested against anything Mr. Crompton could find. He had just lately been able to carry out some improvements which would shortly be made public, and which would enable them to give much more life to accumulators, and to discharge at a more rapid rate. He did not think more had been done at Vienna than at private installations. The manipulation of a battery station was the difficulty, and he did not see that the cost stood in the way at all. The battery system could be carried out very much at the same cost as an alternate-current system, and possibly might be preferable. Perhaps one of the most unique experiences was at Eastbourne, where the installation of alternate-currents had been running for nearly two years, and there had been no accident or mishap, and the machine had run without any stoppage or cessation of light. He had mentioned these points, not with the view of throwing up any fireworks, but as Mr. Crompton had described what he had done he thought it as well to state what others had done.

After a few observations from Mr. W. H. PREECE the discussion was adjourned until the Thursday following (last night), with the understanding that Mr. Preece would then resume his speech.

(To be continued.)

REPORT ON LIGHTING THE CHELSEA TOWN HALL BUILDINGS WITH ELECTRIC LIGHT.

The following is the full text of the report presented to the Chelsea Vestry Hall Building Committee by Mr. G. R. Strachan:—

"Ten electric lighting companies were asked to give estimates of the cost of laying plant and providing the necessary lamps, apparatus, &c., for lighting the Town Hall with the electric light; and, for their guidance, the following standard of light was given:—

Town Hall	3,200 candle-power.
Council chamber	350 ,, ,,
Platform ante room	Light in same proportion to above.
Committee room	
Lower hall	
Main corridors	

In all other matters the firms were given a free hand to tender as they deemed best. The whole of the firms responded to the invitation. Eight of them proposed to supply the light by a separate installation on the premises, and two of them—the local companies—proposed to supply the current from a central generating station. Of the eight who proposed to supply a separate installation, two proposed the use of gas engines and six the use of steam engines to drive the dynamo.

"If a separate installation is laid it will be necessary to have an engine and dynamo working on the premises. Some amount of vibration will be experienced in working them, but with first-class machines and a solid foundation it may be reduced so as not to be an annoyance. One of the firms—Messrs. Drake and Gorham—have tendered for a duplicate set of engines and dynamos, so as to have provision at hand in case of a breakdown. The other firms have either included accumulators in their estimates, or have expressed the opinion that they should be provided. An accumulator acts the part of a gasometer for the electric light. The energy is stored in it, so as to be at call when a breakdown occurs. It also ensures steadiness of the light. Insulated wire cables would be laid from the accumulators and dynamos to the rooms to be lighted to convey the current to the lamps. Switch-boards would be fixed to enable the currents to be turned on to the different rooms at will. In the Town Hall itself the lamps would be connected to two circuits, so that, in the event of an accident to either of the circuits, half of the lamps would be in lighting. The cables and wires would be provided with cut-outs. These are, practically, short pieces of metal, which fuse if the wires or cables get heated, and so cut out the current before danger from fire could arise. The lamps used would be incandescent lamps, and would be provided with a switch, by means of which the light could be turned on or off at pleasure. If any lamp failed it would not disturb the light in the other lamps. One of the firms—Messrs. Crompton and Co.—have estimated for providing new electroliers and fittings throughout, but the others have estimated for combining the electric lighting to the present gas fittings. This would be done without interfering with the use of the gasaliers for gas lighting.

"If the electric current is taken from the local companies it would be passed through an accumulator, and will be at command like gas. A meter for measuring the current will be fixed, and the Vestry will pay for what is used. The description given as to the cables and lamps, &c., would apply to this method.

"The prices for which a separate installation is offered vary from £1,935 to £800; but these figures afford no guide whatever to the determination of which of the tenders is the most desirable. A study of them resolves itself into a question of what is not included in the sum. Some include accumulators; some fittings and electroliers; while some exclude wiring, builders' and decorators' work, foundations for engines, &c. Quality of work and workmanship have, no doubt, something to do with the difference of price. In the comparative list given hereafter I have added to each of the tenders a sum equal to that which would have to be spent to complete the installation and the work, so as to reduce—or rather, enlarge—them to something like a standard.

"The amount of light asked for is somewhat in excess of that usually provided. Some of the firms have pointed this out, but have estimated for the quantity specified, while others have reduced the quantity to that they deem necessary. Hence the tenders vary from 306 to 234 lamps of 16 candle-power. I have in every case added a sum to the tenders of those who have lessened the light to allow of the light reaching that specified, in order to facilitate a comparison.

Digitized by Google

"The firms have each supplied an estimate of the annual cost of running the light for 1,000 hours a year, and maintaining it. These estimates vary from £558 to £246. The sums stated are not comparable, and afford no hint as to the most economical installation. One firm includes £182 a year for labour and superintendence, while another does not include any sum for these items, although they call attention to the fact that something will have to be added for them; one firm puts the lamp renewals at £90, while another allows £10; one firm estimates the life of the lamps at 2,000 hours, while another says 1,000 hours; one firm puts coal at 20s. per ton, while another puts it at 16s. per ton; one firm allows £150 for depreciation, while another allows £36.

"It is impossible to reconcile these differences; they are as amusing as they are perplexing. I have, therefore, as a rough means of arriving at a comparative statement, reduced them to a standard. In each case I have allowed £78 for labour; 1,000 hours as the life of the lamps, and 300 as the number necessary, or a sum of £63. 15s., which equals their value; coal has been calculated at 20s. per ton; oil, waste, &c., have been put at £20; depreciation has been calculated on the total sum, including such added sums as are necessary to complete the installations, at the rate of 7½ per cent.; while interest on the capital has been calculated at 4 per cent. The estimates, after being crushed into this mould, are scarcely recognisable; but the result affords a safer guide than the estimates themselves.

"In all the estimates the lighting has been taken at 1,000 hours per year, so as to have a common basis. The present gas bill for this time would be £180. The cost of gas is 2s. 5d. per 1,000 cubic feet. One thousand feet of gas give 3,200 candle-power per hour, or a cost of ·145d. per 16 candle-power per hour. An addition to this sum must be made for gas burners, globes, &c., making the net cost equal to ·15d. per 16 candle-power per hour, or about one-seventh of a penny. These figures do not include any charge for capital or depreciation of the gas fittings, as these are necessary in any case. In the present stage of electric lighting it would not be desirable to do without the means of lighting by gas.

"At the same time it is well to point out that a sum of £726 is sunk in the gas pipes and fittings. This, at 4 per cent. interest, equals £29. 1s. per year, and, allowing £20 a year for depreciation, it equals a charge of £49. 1s. per year. Working this out at 1,000 hours a year it equals a charge of ·04d. per hour per 16 candle-power, which, when added to the ·15d. per hour, makes the total cost of gas equal to ·19d. per 16 candle-power per hour. This latter sum does not represent the cost saved by using the electric light, for the capital in the gas pipes and fittings would not be recovered in the change. It represents the cost of gas for comparison with electric light if the Town Hall had neither gas fittings nor electric light fittings, and the Vestry was bold enough to do without gas. The cost for comparison is ·15d. per 16 candle-power per hour.

"The following is a table of the annual costs of the systems tendered for when the estimates have been standardised:—

	Annual Cost. £	s.	d.		Cost of 16 candle-power per hour. d.
The Chelsea Electricity Supply Co....	583	7	0	...	·467
The Cadogan Electric Light Co.	536	8	4	...	·429
Messrs. Drake and Gorham	516	5	6	...	·413
Messrs. Siemens Bros. and Co........	502	7	0	...	·402
Messrs. Edison, Swan and Co.........	483	11	9	...	·395
Messrs. Crompton and Co.	462	4	0	...	·369
Mr. Ronald Scott	453	15	0	...	·363
Messrs. Smith and Co.	450	13	0	...	·361
The Anglo-American Brush Co.	444	5	0	...	·355
Messrs. Holmes and Co.	440	14	0	...	·353

"It may be taken that the cost by a separate installation will be from 2⅓ times to 2⅔ times the cost of gas, and the cost from a central station will be three times that of gas.

"The following were the estimates sent in by the selected firms:—

"CHELSEA ELECTRIC COMPANY.

"This company proposes to supply the current from a central station, and to charge for the electricity by meter. Their estimate for providing conductors, wires, casings, switches, cut-outs, eight circuits, 291 16 candle-power incandescent lamps, and plain electric fittings, is £507. 10s. They propose to supply the current at 8d. per Board of Trade unit, which is between ½d. to ⅓d. per 16 candle-power per hour. The company has not a central station yet. They estimate the annual cost, allowing 1,000 hours for the life of the lamps, at £543. 4s. This estimate standardised is:—

	£	s.	d.
Lamps and current	£543	4	0
Interest on £507 at 4 per cent.	20	3	0
Depreciation on fittings	20	0	0
	£583	7	0

Or ·467d. per 16 candle-power per hour.

"CADOGAN ELECTRIC COMPANY.

"This company proposes to supply the current from a central station, and to charge for the electricity by meter. Their estimate for providing conductors, wires, switches, cut-outs, six circuits, 235 16 candle-power lamps, adapting the gaseliers to the electric fittings, &c., is £566. 19s. They would provide and keep in order at their own cost an accumulator to hold current for six or seven hours. The charge for the current will not exceed 7d. per Board of Trade unit, which they say is as near as possible ⅓d. per 16 candle-power per hour. (According to the usual means of calculating the cost the price would have to be less than 7d. per unit to reduce the cost to ⅓d. of a penny per 16 candle-power lamp per hour.) The annual cost would be:—

	£	s.	d.	£	s.	d.
300 lamps for 1,000 hours each, at ⅓d. per lamp per hour..				£426	13	4
Depreciation				20	0	0
Interest at 4 per cent. on	£566	19	0

PETITION IN FAVOUR OF LORD THURLOW'S ELECTRIC LIGHTING BILL.

At a recent meeting of the Electrical trade held at the offices of the Anglo-American Brush Electric Light Corporation (Limited) it was decided to petition in favour of Lord Thurlow's Bill now before the House of Lords to amend the Electric Lighting Act of 1882, and the following petition has been extensively signed by the principal electrical companies and firms and by gentlemen representing the scientific interests of the industry :—

"IN THE HOUSE OF LORDS,
"SESSION, 1888.

"ELECTRIC LIGHTING ACT (1882) AMENDMENT BILL.

"PETITION IN FAVOUR OF THE BILL.

"*To the Right Honourable the Lords Spiritual and Temporal in Parliament assembled :—*

"The most humble petition of the companies and persons being traders and persons interested commercially and scientifically in the subject of electric lighting in the United Kingdom whose seals and names are hereunto attached and subscribed.

"1. A Bill is now pending in your Lordships' House, intituled 'An Act to amend the Electric Lighting Act, 1882,' and having for its especial purpose the extension from 21 to 42 years of the period limited by the aforesaid Act of 1882, after the expiration of which local authorities may

Digitized by Google

have an option of purchasing electric lighting undertakings within their district, and being in respect of the aforesaid extension of time based upon the report from the Select Committee of your Lordships' House on various Electric Lighting Bills in the year 1886.

"2. Your petitioners claim to represent the commercial and scientific interests of the United Kingdom on the subject of electric lighting, and are of opinion that the proposed extension of the aforesaid period and other amendments of the existing law proposed by the said Bill will so far lessen the restrictions which have hitherto prevented the industry from developing as to enable at least some progress to be made in its development.

"3. Another Bill has been introduced into and is now pending in your Lordships' House, intituled 'An Act to Amend the Electric Lighting Act, 1882,' and bearing the short title of 'Electric Lighting Act, 1882, Amendment (No. 2) Bill,' the object of which is to effect far-reaching changes in the existing law, which, while they might very possibly attain the object in view, raise weighty and complex questions connected with the powers of local authorities; and your petitioners are very apprehensive that the discussion of these questions must necessarily lead to further delay in affording relief of which the public desirous of having the advantage of electric lighting and the electric lighting industry is so urgently in need. Your petitioners therefore respectfully submit that the Electric Lighting Act, 1882, Amendment Bill firstly hereinbefore referred to, which is based as aforesaid upon an exhaustive inquiry which has already been held, ought not to be delayed pending any inquiry which may be considered necessary into the proposals contained in the Electric Lighting Act, 1882, Amendment (No. 2) Bill, and that if the proceeding with the last-named Bill would have this effect it should not be proceeded with.

"Your petitioners therefore most humbly pray your Lordships that the Electric Lighting Act, 1882, Amendment Bill, may be allowed to pass into a law in the course of the present Session, and that the Electric Lighting Act, 1882, Amendment (No. 2) Bill, may not so far as its proceeding will delay the passing into law of the previous Bill be allowed to proceed.

"And your Petitioners will ever pray."

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April 7th*, 1888.

In my last letter I made reference to the troubles which had arisen between Mr. Gould and certain of his opponents, Mr. Gould claiming that certain lawyers were trying to blackmail him in connection with railroad matters, and that among their allies were the *New York Herald* and the Commercial Cable Company. This gentle accusation was, of course, denied, but it was followed up on Sunday last by an open letter published in nearly all the newspapers, including the *Herald*, from Mr. Gould to Mr. Bennett. This letter has caused an immense sensation. In it Mr. Gould traces Mr. Bennett's bitterness and opposition to him back to some early negotiations connected with the American Cable Company and the American Telegraph Company. Mr. Gould alleges that the *Herald* then demanded lower rates than were paid by other newspapers, and a precedence over them in the transmission of news. "In other words, you were attempting to use the corporation of which you were a trustee not only for your personal profit and advantage, but to the injury of your rivals. I stated, further, that your attempts were so persistent and so offensive that at the first opportunity your name was dropped from the Board." In support of this statement, Mr. Gould prints a memorandum made at the time by one of the directors, which further alleged that the bitterness of the *Herald* had been intensified since the refusal of the "cable pool" to allow the French Company to renew its contract with the *Herald*, at special rates, at about half the price the other papers were being charged; the failure of this effort leading to the establishment of the Commercial Cable system. At this point of the letter Mr. Gould waxes warm, and apparently losing self-possession, pitches into Mr. Bennett with some of the most extraordinary personalities that ever found their way into New York journals, which are not noted for squeamishness in this respect. Mr. Gould, in fact, tells some piquant stories about Mr. Bennett's debaucheries and sprees, and winds up with a horrible yarn about Mr. Bennett landing some yachting guests at the Morgue, and himself tumbling into one of the coffins there. I need go no further to indicate the nature of the letter, having said enough to show why all New York, and for that matter all the United States, is talking about it. These personalities certainly "have nothing to do with the case," whether it be the railroad litigation or the cable war, but their presence is taken as an indication in electrical circles that we are not likely soon to see the cable compromise which was so confidently expected not long since.

Now that the great telephone litigation is practically settled, some of the newspapers are promising us a big lawsuit between Mr. Edison and Mr. Bell regarding priority of invention in the phonograph and graphophone field, it being alleged that while Mr. Edison has brought out the phonograph, Prof. Bell was the first to give it its practical shape. The New York *Sun* published a few days ago quite a long article, in which it stated, with all circumstantiality, that the suit in question was, however, to be only collusive, that the graphophone and phongraph interests would join hands, and that simply one type of machine would be presented to the public for patronage. This story hardly coheres with some of the facts of the case, for it is well known that both phonographs and graphophones are being made to-day, and if there is to be any sort of immediate understanding, one machine or the other would be dropped. The article in question states that it is the intention to build a thousand of the graphophones, and that three hundred have already been made. These instruments are to be handled on telephonic business principles—that is, they are not to be sold outright—but to be leased, and the rate is to be not less than $60 dollars each per annum. The machines are said to be in good shape, and to be easy to manipulate. The instrument complete is somewhat smaller than the ordinary typewriter, and the ordinary wax tube which takes the impression is about seven or eight inches long, and an inch in diameter, having a capacity for about 250 words. Those who are handling the invention say that it will supersede stenography, which is very much doubted by the stenographers.

Another ingenious device of quite a different character is that which has just been put upon the market by a company manufacturing under the patents of Mr. P. B. Delany, whose synchronous multiplex telegraph system has been adopted by the English telegraph department. This device is intended as a protection for linemen and others against electric shock. It consists of a pair of broad linked bracelets, which encircle the wrists, and another pair which, like garters, clasp the leg just above or below the knee. These are connected in such a way that the wearer may be said to have a flexible lightning rod down his back. The claim is made that by this electrical *bijouterie* large enough portions of dangerous currents can be shunted to save life, the portion of shunted current depending, of course, on the moistness of the skin and the closeness of contact between the bracelets and the arms and legs of the wearer. It is proposed, I believe, that the connections shall be concealed under the coat of the lineman, who otherwise would probably be the object of very marked attentions as he proceeded to answer duty's call along the busy thoroughfares of the city. Experts who have seen it consider that the device has no small merit, and think that the only trouble would be in getting the average lineman to deck himself out in this glittering splendour and shawl strap paraphernalia.

I learn Professor Forbes leaves here to-day, and his present visit to the United States has been most agreeably, and I trust, profitably spent. There is a report current, by the way, that he has made an advantageous disposition of his meter, or the patents thereof, for this country.

An important hearing has been had this week before Judge Wallace in the United States Circuit Court for this district in the equity suit of the Edison Electric Light Company against the United States Electric Light Company. This suit dates back to the beginning of 1885, and affects six of Mr. Edison's leading electric light patents. The decision that is asked for from the Court does not touch the direct and main issues, but is relative to the effect which the limitation and expiration of foreign patents has upon the United States patents. As you are doubtless aware, it has already been decided in one or two cases that, under Section 4,887 of the United States Revised Statutes, the term of a United States patent is limited by the shortest term of any corresponding patent which had "previously" been taken out in a foreign country. It is contended,

Digitized by Google

however, that the section referred to has never been properly and thoroughly interpreted, and that its muddy and confused language must not be construed in any way to injure the American inventor in his own country, or those who may hold from him. In the present case it is argued that there is no evidence to show that the foreign patents—Italian, Austrian, &c.—or the original terms thereof, have expired. The question is raised whether the section, after all, has any application at all to the American inventor or patentee whose invention was made and reduced to practice in the United States, and who has in every respect complied with the law; and, next, whether an opportunity should be afforded to any inventor, who has assigned his invention, to deliberately defraud anybody, as he might, by getting a foreign patent in such a way as to invalidate rights which he had already sold, leaving the field open for new rights and a new sale on some modification of the thing invented. I could go into the matter in more detail, but have said enough to indicate the importance of the subject. There is a very general feeling that this principle of limiting the term of American patents so arbitrarily, even if it be found embodied in the present law, is a very bad and harmful one, and that, if necessary, the law should be changed. In order to avoid the uncertainty which thus, under existing conditions, cloud patents taken out abroad as well as at home, in this particular respect, American attorneys and patentees are put to very great trouble, inconvenience, and embarrassment—the counter good to which nobody can perceive. This big question has never been adjudicated upon by the United States Supreme Court, but will probably reach it upon appeal in the present instance, whichever way the decision goes in the lower court. It will undoubtedly be a great relief to have the points settled definitely and finally, though, if the settlement be left to the Courts, and no change be made in the law, should it require it, we must wait at least three or four years.

There is no little activity at present in electrical literary circles. You have already noted from time to time the extension of the field of electrical journalism in the United States, and may now add the announcement that another electrical publishing company has been formed in Chicago. In regard to books, I may mention the appearance of a very handy little book giving instructions to dynamo tenders, in the construction, maintenance and operation of electric light and power plants. It is publised by the *Western Electrician* Company, of Chicago. The author is Mr. F. B. Badt, who was at one time, I believe, an officer in the Prussian army, and is now connected with electric lighting in Chicago. Another book, which is in fact of the first importance in many respects, is that by Carl Hering, on "The Principles of Dynamo Electric Machines." It is the first book of the kind published in America, if we except such works as that of Prescott, and the translation made by Keith, of Schellen. It deals with the designing and construction of dynamos, and contains an appendix of no mean size, embracing articles on several allied topics. The book is published by Mr. J. Johnston, and will, I suppose, reach you in due time for review. I hear that a large sale is expected for it in this country. This month has seen also the appearance of no fewer than three electrical articles in the leading magazines. In the *Century*, Mr. Frank L. Pope has a very interesting illustrated article on "The American Inventors of the Telegraph," with special reference to the work and services of Alfred Vail. In the *North American Review* Mr. T. C. Martin has a picturesque article on "Gilbert's Tables," in which, dating from the first exhibition of the Morse telegraph in New York, in 1838, he traces, with striking details and statistics, the practical development of electricity in this country. A third article on "The Dawn of Electricity," by Dr. Park Benjamin, appears in the *Forum*, in which the writer gives a remarkably able and vivid sketch of the career and work of Dr. Gilbert. This article strikes one as having been a labour of love with Dr. Benjamin, for it is a masterly rehabilitation of the character and achievements of the old English worthy. It is said that the author has made some very exhaustive studies in early electrical literature, and if the present article be a sample of the results it is to be hoped that he will soon give us some more of them.

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-NIGHT) FRIDAY, April 20th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "The Speed Trials of the latest addition to 'The Admiral' Class of British War Vessels." By Mr. DAVID S. CAPPER, M.A., Stud. Inst. C.E.

ROYAL INSTITUTION.

9 p m. Lecture, "Antagonism." By the Right Hon. Sir WM. R. GROVE, M.A., LL.D., F.R.S., M.R.I.

SATURDAY, April 21st.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Later Works of Richard Wagner" (2). By Mr. C. AMBRUSTER.

MONDAY, April 23rd.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture V. "Milk Supply and Butter and Cheese-Making" (3). By Mr. RICHARD BANNISTER.

INVENTORS' INSTITUTE.

8 p.m. Ordinary Meeting.

TUESDAY, April 24th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read, with a view to discussion, "The Distribution of Hydraulic Power in London." By Mr. E. B. ELLINGTON, M.I.C.E.

SOCIETY OF ARTS.

8 p.m. Applied Art Section. "Craftsman and Manufacturer." By Mr. LEWIS FORMAN DAY. Mr. J. SPARKES, Principal of the National Art Training School, will preside.

ROYAL INSTITUTION.

3 p.m. Lecture, "John Ruskin" (3). By Dr. C. WALDSTEIN.

ROYAL VICTORIA HALL (Waterloo Bridge-road, S.E.).

8 p.m. "Soap Making." By Mr. W. P. BLOXAM.

WEDNESDAY, April 25th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "The Physical Culture of Women." By Miss CHREIMAN. Dr. RICHARDSON, M.A., F.R.S., will preside.

CITY AND GUILDS OF LONDON INSTITUTE (Central Institution), Exhibition-road, S.W.

7:30 p.m. Meeting of Old Students' Association. Paper on "Solution." By Mr. H. CROMPTON.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

7 p.m. Paper on "Railways for Rural and Undeveloped Districts." By Mr. J. B. WALTON, M.I.C.E.

THURSDAY, April 26th.

SOCIETY OF TELEGRAPH-ENGINEERS.

8 p.m. Extraordinary General Meeting at the Institution of Civil Engineers. "On the Risks of Fire Incidental to Electric Lighting." By Mr. W. H. PREECE, F.R.S., Past President.

ROYAL SOCIETY.

4:30 p.m. Ordinary Meeting.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Chemical Arts" (3). By Prof. DEWAR.

FRIDAY, April 27th.

ROYAL INSTITUTION.

9 p.m. "Electrical Influence Machines." By Mr. JAMES WIMSHURST, M.R.I.

SATURDAY, April 28th.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Later Works of Richard Wagner" (3). By Mr. C. AMBRUSTER.

PHYSICAL SOCIETY OF GLASGOW UNIVERSITY.

Paper on "Theory of Gases." By Mr. W. COLQUHOUN, M.A.

PHYSICAL SOCIETY (LONDON).

3 p.m. "On Electromotive Force by Contact." By Mr. C. V. BURTON. "A Theory Concerning the Sudden Loss of Magnetic Properties of Iron and Nickel." By Mr. H. TOMLINSON. Note on "The Graphic Treatment of the Lamont-Frölich Formula for Induced Magnetism;" Note on "The Conditions of Self-Excitement in a Dynamo Machine;" and Note on "The Conditions of Self-Regulation in a Constant Potential Dynamo Machine." By Prof. S. P. THOMPSON.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

CONTENTS OF THE CURRENT NUMBER.

LORD CRAWFORD'S BILL.

The Electric Lighting Act (1882) Amendment (No. 2) Bill, which has been brought into the House of Lords by the Earl of CRAWFORD, and was read a second time on Tuesday last, introduces several provisions of a novel and important character; and although in the main we fully agree with the views expressed by Lord THURLOW, that the Bill is altogether too complex and crowded with detail to stand a chance of becoming law at an early date, yet there are several points in Lord CRAWFORD's measure which will repay careful consideration. One of the greatest difficulties encountered under the present Act, and one which Lord THURLOW's Bill does nothing to remedy, lies in the fact that not only is the cost of a Provisional Order, and of the Parliamentary procedure consequent thereon, very considerable indeed, but moreover this course of action can only be taken during a certain limited portion of the year, so that a project in every way commendable may have to be held over for six or nine months before Parliamentary powers can be obtained. Lord CRAWFORD proposes to remedy this by providing an additional method of procedure, under which the local authority would have power to enter into an agreement with and to grant permission to the undertakers to carry out their works without obtaining confirmation from the Board of Trade. But, as was pointed out by the Earl of ONSLOW, electric lighting companies are in this respect no worse off than gas, tramway, or railway companies, who labour under precisely the same disadvantages; and it would be difficult to introduce an entirely new principle affecting the relations of local authorities with public companies on the one hand and with the Board of Trade on the other hand, unless they were prepared to make this principle of entirely general application. We fear that this objection is an unanswerable one.

Clause 3 of Lord CRAWFORD's Bill contains a proposal of a decidedly startling character. It stipulates that the right of supply shall be subject to the observance of certain installation rules which are to be laid down by the Board of Trade. It is, perhaps, a little singular that after explaining this clause Lord CRAWFORD immediately made reference to the rules issued by the Phœnix Fire Insurance Company, stating that he was informed that no extra premium was charged on buildings containing installations put up in accordance with these rules, the inference apparently being that the Board of Trade should adopt and enforce the rules of the Phœnix Fire Office. This would at least tend to afford

Digitized by Google

a solution of the existing deadlock in connection with Fire Office rules. Upon the whole, however, we fear that such a solution would give rise to very considerable jealousy and heartburnings, though we need scarcely regard it at present as coming within the realm of practical politics. A succeeding clause deals with the question of telephones, and is intended, we are informed, "to protect them from all possible damage by an electric lighting undertaking." We should like to have the exact terms of this clause before us before expressing a decided opinion upon its merits. We are not altogether satisfied that the Telephone Companies ought to be allowed to have things entirely their own way, and this for two reasons. In the first place, a divergence may be effected in a telephone line at a very small fraction of the cost which would be required to effect a similar divergence on an electric lighting circuit. In the second place it is well to remember that the Telephone Companies have always the power to protect themselves against all external inductive interferences simply by the adoption of the complete metallic circuit.

It is further provided that within five years from the passing of the Act all cables or mains shall be placed underground. This is one of those stipulations of which the full signification and bearing can at present only be surmised. The Bill, however, contains no provision for the infliction of a penalty upon any company which might fail to carry out this requirement. Lord CRAWFORD also proposes that "when the undertakers are not a local authority, but a company or private individuals, they shall contribute a certain sum per annum to the relief of the rates for the privilege of being allowed to use the streets." He also intimated that a rate of about £20 a mile would probably be considered fair, and that if the Bill got into Committee he should then be prepared "to state the amount which that rate would realise if London were properly dealt with," adding the somewhat cynical observation that "their Lordships would be surprised to learn to what an extent the rates of London would be relieved if this were done." We fear that this remark will tend to damp any dormant enthusiasm on the part of electric light promoters in favour of Lord CRAWFORD'S Bill. The cost of placing mains underground is already so enormous that even the prospect of being enabled to effect an extensive reduction of the rates will scarcely reconcile the promoters to the proposed additional tax. In concluding his speech, Lord CRAWFORD stated that he knew of his own knowledge that "if the law were made somewhat on the lines of this Bill, within six or eight months large sums of money would be thrown into the country and employment provided for a great number of working men." He believed that under these conditions at least 40,000 men would speedily be employed in preparing these works and upon the business of electric lighting. Although we are scarcely able to share the roseate anticipations of the noble lord quite to this extent, we have yet no doubt whatever that the passage either of Lord THURLOW'S Bill in its present shape, or of Lord CRAWFORD'S Bill with such excisions and amendments as we have hinted at, would give an enormous impetus to the electric lighting industries of this country.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The report of the Directors states that the total earnings for the year ended 31st December, 1887, amount to £159,789. 11s. 1d., an increase of £21,123. 10s. 3d., compared with the twelve months to 31st December, 1886, and that the working expenses for the year, exclusive of renewals of cable, amount to £64,315. 19s. 5d., as against £62,604. 0s. 1d., an increase of £1,711. 19s. 4d. The Directors recommend the payment of a dividend of 3 per cent., free of income-tax, making, with the interim dividend of 1¼ per cent. paid on 15th Oct., a total of 4¼ per cent., carrying forward £3,464. 8s, 7d.

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

This action for the infringement of the patent of Edison's (No. 4,576, of 1879) incandescent lamp, and Cheesborough's patent 4,847 (of 1878), for a mode of making uniform the carbon thread which forms the light-giving portion of the lamp, came on before Mr. Justice Kay on Tuesday last.

The Attorney-General (Sir R. Webster, Q.C., M.P.), Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Bremmer appeared for the plaintiffs; Sir Horace Davey, Q.C., Mr. Finlay, Q.C., M.P., and Mr. J. C. Graham for the defendants, who are Mr. Wm. Holland, of the Albert Palace, the Jablochkoff Company, the General Electricity Company, and the Anglo-American Brush Company.

The ATTORNEY-GENERAL, in opening the case, described the patents in question, and claimed that Edison had solved a problem which for forty years electricians had striven to elucidate. In consequence of his invention electric lighting at once leapt from the laboratory to practical commercial use, and these courts would always be a constant record of that fact. If Mr. Street and Mr. Barry had been originally asked whether they had provided for electricity at the time of commencing the courts they would have said that electric lighting was about as far off as it possibly could be.

Sir FREDERICK BRAMWELL, F.R.S., in reply to Mr. ASTON, Q.C., said he had given particular attention to the construction and use of lamps employed in electric lighting very nearly since the introduction of the incandescent method of lighting. He was one of the original shareholders in the Edison Company, and was one now. From time to time during the last ten or twenty years, when various improvements had been made, these lamps had come under his notice. Besides having a professional experience of these matters, he had taken a great practical interest in them. During one of his visits to America in the very early days of electric lighting, he saw what he believed was the first station for distributing light from a central point; and he then also saw the manufacture of the lights. He had made himself acquainted with Edison's patent of the 10th November, 1879, which was the subject of this action. Asked what was the state of public knowledge as regards incandescent lamps at the date of the patent, witness said the very earliest attempt at their construction was by King in 1845. King proposed two modes of making an incandescent lamp—one by means of a platinum strip, which was to be made incandescent in ordinary atmosphere, and the other by means of a piece of carbon made by a saw or file and enclosed within a Torricellian vacuum. There was an enlarged chamber, as it were, at the head of a barometer, which was big enough to contain this portion, and the whole thing was about 30 inches in length. The chamber was made of glass, and he had no doubt the shank was on glass, but the closure at one end of the chamber was mercury. Leaving out of consideration the arc lighting, in 1852 a gentleman of the name of Roberts proposed to use a piece of carbon about half an inch by half an inch, and as thin as it could be made, in a lamp exhausted by an air-pump fitted with a metallic sheet, from which proceeded a pipe with a stop-cock to make the connection with the air-pump, the upper part of the lamp being of glass, secured in the same way to a metallic base. In that way there was a chamber entirely of glass, and, as in King's case, the carbon was cut out of a piece of a carbon already existing.

Mr. Justice KAY suggested that it would be for the defendants to deal with the early history of electric inventions, and that the plaintiffs could then call rebutting evidence, but that they need not go into that matter now.

Mr. ASTON then asked witness whether he had read and considered the various specifications, and made himself acquainted with the specification of the patent of the 10th November, 1879.—Witness said that he had, and that he considered the specification of Edison sufficient to enable an incandescent lamp to be made in the manner proposed by Edison.

As far as you know, what do you say as to the knowledge of incandescent lamps described and proposed to be used by Edison at the date of his patent?—So far as I know, it was new.

So far as your own knowledge and experience go, are you able to point to any successful incandescent lamp which was used prior to the date of Edison's patent?—No. I mean no commercially successful lamp.

Asked whether he meant a lamp which would satisfy the wants of the people who used the electric light in the ordinary way, witness said he had a recollection of platinum incandescent lamps being exhibited and giving a fair light, but since the carbon filament lamp he did not know that anybody had attempted to go on the lines of the platinum lamps. The platinum lamps were used with the ordinary atmospere at a temperature below that which would fuse the platinum. He believed that incandescent lamps were now made with carbon filament, with this exception—that there might be lamps of enormous size which were incandescent and also carbon; but then the question would arise whether the thing could be looked on as a filament in the ordinary sense of the word. Lamps of the size used in lighting the courts, the streets, and clubs and hotels were what he would call carbon filament lamps. At the Athenæum the lamps ranged from 8 candle-power up to 32. He had examined some of the lamps which had been stated to be of defendants' manufacture, and some of them had broken up. The result of his examination was that the lamps were in a very vacuous condition before they were broken, and it was established that they were incandescent lamps possessing a resistance when cold varying from 60 ohms, in two cases, up to 195 or 200 ohms. When heated the resistance would be lowered to perhaps some 60 or 50 per cent. of the original. So far as could be judged by the eye the filament was undoubtedly a carbon filament.

Digitized by Google

Taking it as a carbon filament which was carbonised after the filament was formed, what do you say with regard to it, bearing in mind the description given in Edison's specification ?—I do not distinguish any difference. I do not conceive any difference.

May we take it that the filament was flashed ?

Mr. Justice KAY: What does that mean ?

Witness: That the filament had been treated by the Cheesborough process.

Mr. FINLAY said that it must not be taken that he admitted that it was flashed.

Mr. ASTON (to witness): What had been done to the filament in order to bring it into the condition in which it was when you examined it ?—I believe that it had been heated by the passage of electric current through it while it was surrounded by some carbonaceous liquid or carbonaceous gas, such as coal gas, the effect of which would be to deposit carbon upon it in the greatest quantity where it was hottest.

The fragments of a lamp which had been broken by the witness in his experiments were then produced, and Sir F. Bramwell said that he could not see any difference between that lamp and the incandescent lamp described in Edison's specification, except in points of very minor detail. He thought the sort of secondary wire spoken of by Edison between the carbon and the wire loops was not there, but the carbon was attached direct to the leading wires. He had no doubt from their appearance that they were platinum. Until some difference was pointed out to him he was able to say that that was a lamp which was an incandescent electric lamp wholly of glass in a highly vacuous condition, containing a carbon filament made, he believed, into that form before carbonisation—a filament, according to his belief, of less than 100th of an inch in diameter—he thought it was 6½ thousandths—a filament which he believed had had deposited upon it carbon from out of a surrounding carbonaceous liquid or gas, pointing to internal heat by electric current. Referring to Cheesborough's specification, counsel asked in what way was carbon produced in gas retorts suitable for the purpose mentioned in the specification. Witness said he had no doubt that it was produced by deposition from the gas in the retort itself. He knew a special instance of it very many years ago, where it was done with an object. In a gasworks it was an accident, as it were, of the manufacture, but some years ago, in order to render the coal gas for a balloon light, the gas was passed through retorts to obtain a deposition of the carbon out of the gas, leaving out the lighter gas. He recollected seeing the apparatus. Asked whether the carbon so deposited was in any way used for electric lighting, he said he thought that King referred to it, and that it had been used, as Cheesborough stated, for arc lighting. Cheesborough also stated that a better kind was made by powdering the material, and there were varieties of specifications for purifying the material. Cheesborough went on in his specifications to say that neither the one nor the other quality of carbon—neither that melted nor the one from the gas retort—was suitable for electric lighting by incandescence. The sub-divisions of the material and the pressure necessary to produce a perfect article were practically unattainable. He could not say that he had ever experimented in that direction, but he certainly would expect, as Cheesborough said, that carbon of the ordinary sort when heated by the electric current would exhibit points and lines of unequal brilliance. Asked why he should expect this to occur in carbon of the ordinary sort, even when it was scraped and shaped, witness said it was because carbon of the required homogeneity would have varying powers of conduction, and there would be parts where the resistance would be greater than at others, and where the resistance was greater the parts would be hotter and would glow with more intensity.

The patentee goes on to say, "It has been found that a pencil of carbon immersed in hydro-carbon gas or liquid, and heated to an extremely high temperature with a voltaic current, is not itself attacked, but decomposes the surrounding matter, the carbon of which enters and fills up its pores to an extent impossible except with matter in a very attenuated state; it deposits a perfectly homogeneous layer, generally of a bright grey colour, on the exterior surface, and as the carbon increases in size more current is required to maintain its temperature, and if the current is increased according to the demand made upon it, there is apparently no limit to the increase in mass of the homogeneous exterior deposit." I agree with that. Carbon pencils may be cut from this deposit, and may be used in the lamps. The witness then went on to say that he had had his attention called to the various specifications which were relied upon by the defendants as anticipating Cheesborough's patent. Counsel was proceeding to examine witness upon the novelty of this patent, but Mr. Justice Kay suggested that that should be left till after the defendants' case, when, if necessary, plaintiffs could call rebutting evidence. Witness, in continuation, said that he considered that Cheesborough's specification was a sufficient one. As regarded the filament of the defendants' lamp, which he had examined, he had reason to believe that it was treated by a process such as Cheesborough pointed out.

As far as you know, is the term "flashing" a term commonly applied to the processes which Cheesborough described ?—Yes.

Cross-examined by Mr. FINLAY, witness said he believed that lamps had been made according to the patent of Mr. Edison now in question for commercial purposes and used commercially apart from any subsequent improvements. He could not, however, say of his own knowledge. Only one improvement occurred to his mind, and that was making the vacuum after a current had been put through. With that exception, as far as he knew, the lamps in the court were what he should call thorough Edison lamps.

Do you say that the lamps in this court are lamps made under this patent of Mr. Edison's now in dispute ?—I should think they undoubtedly were.

I appeal to your knowledge ?—You see that that involves my putting an interpretation upon the patent. According to my judgment they are. You tell me they are not; but still that is my opinion, if the patent be what I think it is. If I am wrong, then they may not be according to the patent.

In all electric lamps that have been made since then have not additional processes been applied, some of them secret processes, necessary for the perfection and efficiency of the lamp ?—Not to my knowledge. I know of secret processes employed in the manufacture of the lamp for the purposes of economy and of securing a better light, but I know of no secret processes which have been employed for the purpose of improvement.

Can you give me of your own knowledge any case of an electric lamp manufactured simply under this patent in dispute ?—With the exception of the final exhaustion I should say every lamp almost, according to my point of view of the patent.

What is your view of this patent ?—That there is disclosed there an incandescent carbon filament lamp, the filament being formed to shape before carbonisation, the lamp being wholly of glass and containing a high vacuum, and the leading wires being fused through the glass.

Is the stress laid upon the filament in the view you take of the patent ?—I am not aware that I lay stress upon any particular part of it. I think the filament a very highly important part, and I should say one without which the lamp would not be commercially successful.

Witness was then examined upon the provisional specification, dated 17th June, 1879 (No. 20,402), which, by the use of platinum or metallic wires, secured "pyro-insulation." His recollection was that there was some protective matter on the surface of the wires. Pyro-insulation meant that the wire was introduced into some such substance as oxide of magnesia.

The word filament is used in the specification, and you have used it more than once. What sense do you attach to the word in your evidence and in the specification ?—I think the best illustration is to take the actual cotton thread of carbon. I do not think it may be called a rod of small sectional area. The word rod hardly implies it to my mind.

Asked whether he would call what was shown on the drawing annexed to the specification a thread, witness said there was no scale attached to it. He had to imagine a scale by assuming that that lamp was some such sized lamp as was now known, and, assuming that, he should say it was a very large thread and a very stout one; indeed, more like packing twine or something of that sort. But he paid no attention to that detail in the drawing, having regard to what was stated in the patent, "a cotton thread."

Mr. Finlay here wanted to cross-examine the witness upon the specification of 15th December, 1879, No. 5127, but the Attorney-General objected that that was a specification of later date, and they could not construe a filament in the specification in question by a later specification.

Mr. FINLAY then asked witness whether in this specification the carbon filament was not a tolerably substantial piece of carbon ?—Witness said he did not know whether any directions were given as to the size of this at all, by reference to the patent under consideration, but there was a case where apparently the term filament was applied to something which had a flat section.

Taking it that the leading idea of this patent was the small sectional area for the purpose of increasing the resistance to the electric current, there was nothing novel in that, was there ?—I think there was not by taking any kind of conductor, but I believe there certainly was by taking the carbon.

Take first the platinum—that idea had been developed by Mr. Lane-Fox ?—Yes, I think so. It is perfectly clear from Mr. Lane-Fox's specification that he was fully aware of the value of high resistance in incandescent lamps.

And producing that high resistances by diminishing the sectional area of the conductor ?—I have no doubt; and by using that which to begin with was as highly resisting a metal as he could probably get.

And also with a small sectional area ?—No doubt. The next patent of Lane-Fox, dated 9th October, 1878, looks something like a pyro-insulation. Lane-Fox there proposed to use a material which was asbestos saturated with carbon, but what that may be I do not know.

Witness was then examined upon Mr. Lane-Fox's patent of 1878, No. 4,626. He said he thought that a most elaborate description was given of the carbon lamp in the provisional specification, but that it was dismissed in the most cursory manner in the final, and that there was no drawing whatever of the lamp suggested. The carbon lamp was a lamp which could be opened, and the light was to be made by the contact of a vertical pencil and the carbon at its upper end against the piece of carbon. It was a sort of semi-arc semi-incandescent lamp. Witness was then taken to the Pulverman provisional specification. He said that related to lighting by the voltaic arc. When the patentee came to incandescent lighting he used a fine platinum wire.

Reference was then made to the provisional specification granted to Lane-Fox in 1879; and witness was asked in what particulars that was not an anticipation of the patent now under discussion.

Witness said that Lane-Fox proposed to make a compound material of carbon and a certain non-conducting material pounded finely and mixed together; but there was no suggestion of carbonisation after the materials were so mixed and the bridge was formed. There was to his mind, both as regards material and the mode of manufacture, an important distinction.

Is your first point that it was not carbon alone ?—It was not carbon alone; it is a mixture of carbon and some con-conducting material mixed as a powder. I should think he would have enormous difficulty in making sure that they were equally proportioned throughout the length of the bridge, and if they were not, he would have more and less luminous parts upon it; but even if he could succeed in mixing them up in absolutely the same proportion throughout the length of the bridge, even then there is no carbonisation after the bridge—that is to say, the glowing part—is formed, as there is in the plaintiffs' patent.

Digitized by Google

In the first place it is not carbon alone, but there are two substances mixed as powders; and in the second place the bridge is not carbonised after formation ?—Yes; and I think that is a very important distinction.

In further cross-examination, witness admitted that Mr. Edison in his patent proposed to adopt, not merely simple carbon, but carbon together with a non-conducting, non-carbonisable substance, and that would answer the first of his two points, if that was the only mode in Mr. Edison's patent.

Take the second point, do you put it that the essential point, or an essential point of Edison's patent, is carbonising after the formation of the filament ?—I think so. In Lane-Fox's specification there is a thing I do not understand. Lane-Fox is an extremely able man, but I do not understand his suggestion at the bottom of page 94, No. 1,122, of 1879, where he says:—"In order that the luminous bridge may be as much as possible equal throughout, I make it narrower at and near the ends and in the middle." That does appear to me to be a misdirection.

Is there any other point of difference between this patent and Mr. Edison's ?—It is not clear to my mind that this glass vessel is very fully described. I think, if we did not know a very great deal about it, we should hardly get it from that specification.

In the patent under discussion about six different ways are suggested of making the luminous portion of the lamp. Have you tried to make a filament by the directions given in this patent ?—I have not.

Have you seen the operation of making a filament according to any of the directions given in this patent of Mr. Edison's ?—Yes; I have seen the process of making a thread.

"Properly carbonised and placed in a sealed glass bulb exhausted to one millionth of an atmosphere offers from 100 to 500 ohms resistance to the passage of the current; that if a thread be coiled as a spiral and carbonised," and so forth—Is that the description that you have seen carried into effect ?—Yes.

Then the whole description of the process which you have seen carried out is "cotton thread properly carbonised ?"—In the United States, at Edison's own factory, I have seen them making it direct from the bamboo. As far as I know, that was not under the subsequent patent. The specification here says, "any fibrous vegetable material." I think I saw it made from the bamboo in 1882. It certainly was not before 1882. When I have said that I have seen a filament made out of carbonised thread, I should like to say that that thread was treated, before carbonisation, in a particular way.

How was the thread treated before carbonisation ?—It was treated with sulphuric acid. I do not mind saying that much. But there are certain things done afterwards which, unless his lordship says I ought to say, I would rather not mention.

Was this preliminary process a matter of some importance ?—It was of importance compared with the bare thread.

Then you did not see a filament manufactured simply according to the direction in this specification ?—No. I have not seen a mere untouched thread of cotton or flax forthwith carbonised; but I believe you could be satisfied on that point.

You have not seen any filament manufactured under the directions of this patent of Mr. Edison ?—I must again say that, according to my judgment, that which I saw in New York was certainly made under this specification, which says, "any fibrous vegetable substance," and that thing which I saw being made in New York was most certainly a fibrous vegetable substance. I cannot therefore agree that I have not seen anything made under this specification.

Then you regard this subsequent patent as unnecessary ?—That is a question of patent law. I can quite understand that a man may have a patent, and then have a patent for details afterwards.

The Court then adjourned till the next day.

Wednesday.

Sir FREDERICK BRAMWELL, in further cross-examination by Mr. Finlay, on Wednesday, said that the cotton thread he saw prepared had been treated with sulphuric acid.

What was the process of carbonisation applied to the cotton thread ?—It was put into a vessel surrounded by pounded charcoal and heated. It was either linen or cotton thread. I did not follow the same thread through all the processes, but I saw the various processes.

Was the thread stretched upon a sort of mould ?—Yes. There was a certain thing in connection with the carbonisation which I do not wish to mention, but the thread was so placed as to retain its shape during carbonisation. By this means the amount of "wasters" was diminished, and a larger number of useful filaments was obtained than you would otherwise get.

The object bring to prevent distortion ?—Not to prevent distortion, but to prevent waste by breakage.

Were the filaments tied down to this mould ?—Only by being passed round. I am not quite sure whether the vessel used was formed of plumbago or iron.

His LORDSHIP: A crucible ?

WITNESS: Crucible shape, but not crucible material. It was packed with powdered carbon.

Was a little paraffin or any substance of that sort put in ?—I have no reason to suppose so.

Is not the absolute exclusion of air an essential feature in this process of carbonisation ?—I should say so. Otherwise you run the risk of burning instead of carbonising.

Had the carbonisation of filaments ever been carried on before, to your knowledge, in England ?—Not to my knowledge before the date of Mr. Edison's patent.

Mr. FINLAY: Do you think that any ordinary intelligent workman, in 1879, would have known that it was necessary to pack the jar in the way you have described with powdered carbon ?—I think he would have known it was necessary to pack it either with that or sand or some material which would form an effectual barrier to the access of air.

Would sand be effectual ?—I think you will find that certain prior patentees have used it.

Then you think that the direction in the specification for "proper carbonising" is sufficient, because an ordinary intelligent workman would have recognised that exclusion of air was necessary ?—I think so; so far as I know all carbonising is done by exclusion of air, from the very burning of charcoal in a forest, to the burning of charcoal for gunpowder, which is very carefully done. I do not know whether there is any definition in a book, but carbonisation to me conveys the idea of heating matter containing carbon to a large extent, which is inflammable in the open air, but heating it in such a manner that the air does not get to it.

Is the necessity for the stretchers or the interposition of plates a matter that would have occurred to any ordinary skilled workman at the time of this patent ?—Probably not immediately, but directly he began to manufacture on a commercial scale I think it would be adopted. I may say that the bamboo filaments are not wired. They are simply packed together in a mould.

If the cotton thread were treated in the way you describe without being subjected to the preliminary stage of parchmentising by sulphuric acid, would it yield a filament that would work ?—I believe so.

Questioned as to whether the rubbing of a fibrous vegetable material with a plastic compound (which was one of the processes in the specification) would not result in a filament which would be so friable as to be useless for the purposes of electricity, witness said he believed, as a matter of judgment, that it would not.

"If the carbon thread is liable to be distorted it is to be coiled between copper wire." Does not that indicate that the heat to be employed was lower than the point at which copper would fuse ?—I presume so; that is the heat of carbonisation, not the heat of the lamp.

Before you got to the heat of the lamp the copper would have been removed by the acid ?—Yes.

Is not the temperature used and necessary for carbonisation something approaching 3,000 F. ?—I do not know whether it does not vary with the time. I am not at all clear that by continual application of a lower heat you do not attain the same result as by a shorter application of a higher heat.

For the successful manufacture of a lamp of this kind, is it necessary that the gases in the carbon filament should be occluded ?—I think it is highly desirable, for commercial success; that is to say, a lamp with that process is certainly better than a lamp without it.

The filament would otherwise wear away ?—I have no doubt the life would be materially shorter.

By combustion ?—Either by combustion or by washing, probably by washing.

Is the effect of that combustion that there is a deposit on the bulb ?—Yes.

In the bulb itself there is a certain amount of moisture adhering to the glass even after a vacuum is produced ?—I believe there is an extremely small amount.

What is the advantage of using a filament for the purpose of an electric lamp ?—It enables the ordinary lamps that are required for domestic purposes or in this court to be supplied by a current of comparatively high electromotive force, thereby diminishing the size of the conductors, which is what the patentee states. As an illustration, there are now laid throughout London hydraulic mains for the purpose of supplying power for lifts and things of that kind. The pressure is 700lb. to the inch. Supposing you diminish that pressure to 100lb. you would require seven times the volume of water, and mains competent to deliver seven times the quantity.

That was thoroughly understood before Edison's patent was taken out ?—Yes; it is quite clear that Lane-Fox understood it. It is equally clear that Edison did not know that anybody else knew it. I do not think it was common knowledge.

Was it not generally known to electricians of experience in this country ?—With the exception of Lane-Fox I do not think anybody had got the idea that it was desirable to get a lamp of high resistance.

Did not electricians of experience know that by increasing the resistance you could diminish the main ?—Oh, certainly; or rather that by increasing the electromotive force you could get the same effect with smaller mains.

And the advantages of increasing the resistance by diminishing the sectional area have been pointed out by Lane-Fox and by Edison himself in previous patents ?—I am not clear about Edison, but Lane-Fox certainly.

Then is not the only new feature in Edison's patent now under discussion the use of carbon of small sectional area ?—I cannot say it is the only new feature. I should say that the feature of the patent is that he made the first commercially successful carbon lamp to carry that desideratum into practice.

Had not Swan, in 1879, before the date of Edison's patent, produced electric lamps with carbon burners ?—So I am informed; a lamp, or lamps.

Did Mr. Swan produce lamps before the date of Edison's patent with carbon burners, sometimes in the form of a carbon stick and sometimes in the form of a filament ?—Yes, as regards the latter part of the question; and no, as to the other.

A lamp was produced and handed to witness, and he said it looked like the lamp which he had seen before.

The ATTORNEY-GENERAL hoped it would be carefully handled, as it was the only one.

Mr. FINLAY: In that the filament or rod, or whatever you choose to

Digitized by Google

call it, is straight. In other lamps which Swan made was not the pencil or rod of carbon thinner and in a curved form?—I have no knowledge of any other.

Now take that lamp produced, with a carbon pencil straight between two points, what do you say is the difference between it and a lamp made under Edison's patent?—In my judgment that carbon rod or pencil has been made after carbonisation—that is to say, it has been formed out of a piece of charcoal, and I believe it to be a lamp of very low resistance; incompetent, therefore, to attain the end that Edison desires to attain.

What leads you to the conclusion that the filament there was formed out of carbon already made?—It is one of these straight sticks which I should expect would result from such an operation.

Is that your only reason?—I think that is my only reason. It is a stick perfectly competent to have been made out of a piece of prior existent charcoal. I do not know whether, by examination with a microscope anything could be seen that would alter my answer.

What leads you to the conclusion that that is a lamp of low resistance?—The large diameter and the short length. I can only judge by that. But assuming the diameter to be even as little as one twenty-fourth, yet a common diameter of one of these filaments is one-thousandth of an inch, which would give one ten-thousandth as the area, and the resistance would be inversely to the area.

Then what is the difference between Swan's lamp and Edison's lamp?—The difference is that in Edison's lamp you have this small sectional area.

Then it comes to this—that Edison patented a process for making a filament with a small sectional area?—I would rather not say that. He obtained a process for making a filament that would attain the end he wanted, and I think that was done by him for the first time.

Here are some specimens of conductors which I suggest were made by M. Carré in pursuance of a process that he had practised long before Edison's patent, and used by Swan and Stern; do you recognise them?—No; I know nothing about them.

Would you say that the filaments had been formed before carbonisation?—Their appearance is certainly consistent with that.

Carbon had been in use for incandescent lamps?—It had been proposed by King and by Scott.

Would you call those burners of M. Carré's filaments?—I do not know. They are very large filaments. Two of the long ones might be called filaments. I do not know where the term would begin or end.

Now, with regard to Cheesborough, have you seen the process, as used by the defendants, of flashing?—Yes. It consists in placing the filament in a vessel filled with coal-gas, and then passing an electric current through the filament, until the point of decreased resistance is reached, occasioned by the deposit of carbon on the filament, which is indicated on the galvanometer.

Is not the only object of that process the making of all the filaments of the same total resistance?—I do not think so.

That is one object, is it not?—It is one result.

Is there any other object?—I think so; the obtaining of a filament which in itself gives a uniform light, and having a deposit of carbon of very good quality.

Are not the filaments made by the defendants' process such as not to require the flashing for the purpose you have just mentioned?—I do not know. I have had no means of testing it.

It is a form of carbon deposit, a sort of graphite, is it not; by the application of heat to carbon in coal gas it is decomposed, and there is a carbon deposit in the form of graphite?—I believe so, but I would rather leave that to the chemists.

It has been known for a very long time that by the application of heat a deposit of carbon of this kind could be obtained from such a gas as coal gas?—Yes; I knew it as long ago as the date of the Nassau balloon—forty or fifty years ago.

King's patent of 1845 says that the form of carbon found in gas retorts which have been long in use is well suited for this purpose, and may be worked in the form of pencils. Is not that form of carbon the same substance as is deposited by this process?—I should doubt it. At all events Cheesborough does not think so, because he refers to this kind of carbon as unfit for the purpose.

It is like it?—I would rather leave that to the chemists. Cheesborough says he is going to cure it.

In Harrison's patent, he says that one of his improvements consists of placing a piece of metal in a gas retort for the purpose of receiving a deposit of gas carbon. That is the same form of deposit, is it not, but effected by the application of external heat instead of a current of electricity?—Yes.

It is done by the application of furnace heat?—Yes.

But it is the same process?—Certainly not. It departs so entirely from it that I cannot assent to its being the same process.

The chemical process is the same; it is a deposit of hydrate of carbon?—I cannot assent to its being the same process.

Referring to Jacquelin's patent, No. 2,556, that is the same chemical process, using external heat, is it not?—It seems to be the same as the previous one, except that he takes a purer material—he uses heavy oils.

And the same process is explained in a paper by M. Sidot?—He employed sulphate of carbon and a variety of other things. He succeeded in making charcoal so dense as to be sonorous, and he made a bell of it.

That is by the application of external heat?—Yes. There appears to be this distinction between this process and any you have previously referred to, that the change of wood into carbon, and the deposition of carbon, are going on simultaneously. Whether that has any effect I do not know, but if carbonisation is done first we do not get this sonorous carbon, and when we do it simultaneously we do get that result.

In a paper by M. Deprez published in the *Comptes Rendus* in 1841, this process is described as taking place by electricity, is it not?—Yes, as regards portions of it; he tried it in the arc.

Experimenting for the volatilisation of carbon he found this result accidentally?—Yes; his sole object was to find whether he could fuse or volatilise carbon by heat generated by an electric current.

In the course of that paper he describes the obtaining of exactly the same result as pointed out in Cheesborough's patent, does he not?—I think he does. I am not clear whether he does it by Cheesborough's process or not. Deprez tried experiments sometimes by passing an electric current through and sometimes by subjecting the thing on which he was experimenting to the heat of an electric arc, his object being fusion. He then tried a vacuum and azote, and then hydro-carbon. Whether it was heated by a current through wire or in the arc I do not know. It seems to me a matter requiring consideration.

Subject to that it is the same thing?—Yes, but there is nothing there to disclose the advantage for electric lighting purposes. It appears to me that there was not that gradual application of the current which Cheesborough points out. Deprez only desired destruction, and there was no reason why he should do so by gradual steps.

What do you say there was new in Cheesborough's patent?—The disclosure that by electrically heating carbon in a proper liquid or gas atmosphere, you cured the defect that he points out as existing in retort and other carbon for incandescent electric lighting purposes.

He mentions beeswax, balsam and oils; do you treat those as hydrocarbon?—I presume so, but I would rather leave it to the chemists.

He says almost any hydro-carbon would answer; what do you understand by "surrounded by carbonic gas of a very high temperature"?—Such carbonaceous gas as would result from the heating of hydro-carbon. Carbonic gas was what Deprez was trying to obtain—that is, the vapour of pure carbon.

He says the invention is not confined to the treatment of carbon alone, since it is obvious that many fusible substances, non-conductors of electricity, might be heated so as to cause them to be conductors; what does that refer to?—It seems to me to be a sort of guarding clause.

Re-examined by the ATTORNEY-GENERAL, Sir Frederick Bramwell said that he did not find in any other patents that Mr. Edison's patent had been anticipated. He did not think that any practical person acquainted with carbonisation would have any difficulty in carbonising in accordance with the terms of Edison's specification.

Do you think that for practical purposes, even now filaments could be usefully made except by forming them before carbonisation?—No.

You stated that the application of furnace heat was not the same as the application of internal heat—what is the effect upon the deposit?—Where heated from without, no matter what may be the varying section of the thing heated, it is heated uniformly, and the deposit is uniform. When heated from within, the heat is greatest at the thinnest parts, where it is most required, and the increased deposit goes to make greater uniformity throughout.

In Cheesborough's specification it is stated that carbon of the ordinary sort heated by the electric light exhibits lines of unequal brilliancy, and as the carbon was increased in size more current is required to maintain its temperature. In any one of the alleged anticipations do you find any remedy pointed out, or any directions to cure those unequal points of brilliancy by heating with an internal current?—No, not in any one of them. I think I am right in saying that among all the anticipations relied on there are only two wherein there is internal heating by electricity.

Sir HORACE DAVEY: Which are those?

WITNESS: One is Sir William Groves, who heated a metallic wire; and the other is Deprez, assuming that when he did give this heat he used the hydro-carbon gas, which there is much doubt about, as he was heating for purposes wholly unconnected with electric lighting.

Would anybody be led by Deprez's process who desired to find a carbon for electric lighting?—No; I do not think there is any disclosure in that process that would ever lead to an improvement in carbon for an electric plant.

Dr. JOHN HOPKINSON, who was the next witness called, stated that he had given great attention to electricity for many years, and had followed the development of incandescent lighting from the very first. He believed that one or two of the first incandescent lamps that were brought into this country were sent to him. Dealing with the provisional specification of the patent No. 4,576, of 1879, which was the one relied upon by the plaintiffs, he considered that the descriptions given were undoubtedly sufficient to enable a workman to construct the lamp. He agreed generally with Sir Frederick Bramwell's evidence with regard to the various points in the specification.

With regard to this invention having rendered electric lighting practicable on a large scale, what is your opinion?—I do not think there is a shadow of a doubt about it. Before this patent there was no commercial incandescent lamp at all, and immediately after it, or almost immediately after it, incandescent lamps were sold in considerable quantities.

And the electric lamps that have been made and sold generally since the patent, are they made in accordance with the invention?—I think practically all of them are made in accordance with it; no doubt in some cases with improvements in detail.

Now, with regard to the difficulty that has been suggested of carbonising so small a body of carbon, in your opinion would a competent workman find any difficult in doing it?—No; I think it had already been disclosed that one way was to enclose the body to be carbonised in plumbago, and then apply to it a higher temperature; and that is a tolerably obvious way of doing it.

In your opinion would the necessity of some care in carbonising so small a body be obvious?—Yes; it is very clear that with so small a body as a thread the presence of even a small quantity of oxygen would burn it. You must therefore provide something that would combine with it, such, for example, as plumbago or powdered charcoal of any kind.

Do you agree with Sir Frederick Bramwell's evidence as to the effect of

Digitized by Google

coiling and the novelty and utility of the patents relied on by the plaintiffs?—Yes.

Cross-examined by Sir HORACE DAVEY: The first incandescent lamps were shown to him before the time at which the original Edison Company was formed, and certainly subsequent to Edison's patent. If the Edison Company was established in 1882, it was in 1881 that he saw the first lamps.

Do you not know that all through 1880 and 1881 Mr. Swan was making and selling lamps?—I believe he was. I do not know that I saw them, but it is possible.

Perhaps you were at the Electrical Exhibition in Paris in 1881; did you see Swan's lamps there?—I was there, but I do not remember seeing Swan's lamps there. I saw Edison's.

Mr. MOULTON: Do you suggest that Swan's lamps were sold in 1880?

Sir HORACE DAVEY: Yes, and exhibited. Will you tell me, Dr. Hopkinson, if you ever in the course of your life saw a single lamp made exclusively from the directions in the patent without the aid of subsequent inventions or subsequent directions?—Yes. I think that a lamp has been shown to me that was made from a composition of tar and lampblack, or something of that kind, at the time of the last action. I do not know whether it was put in evidence, or whether it can be produced now.

Sir HORACE DAVEY: I should like to see it.

WITNESS: I have not got it.

You do not know how the burner was made?—Not of my own direct knowledge, but I was told how it was made.

You do not know how the burner was attached to the conducting wires?—That I do not distinctly recollect, but my impression is it was attached in the same way as described in Edison's specification.

With the exception of that lamp did you ever see any lamp made exclusively from the directions in the specification?—I do not know that I have seen any lamp without some of the subsequent so-called improvements being introduced.

The burners in the lamps which the Edison Company are selling now are not made in any of the ways pointed out in this specification, are they?—They are made in the ways pointed out in this specification with the addition of improvements in detail.

They are made of parchmentised threads, are they not?—I believe that is so.

Treated in the way that Sir Frederick Bramwell referred to, and did not wish to explain fully?—Yes.

You never saw them made with a thread of cotton simply carbonised?—I do not recollect it, but I may have seen it.

Did you ever try to carbonise a thread from these directions?—No; I have never attempted to carbonise a thread or anything else.

Was there any experience prior to the date of Edison's patent of carefully carbonising threads and fibres?—Not that I know of.

So that your view is that it was a new manufacture?—Yes.

And therefore I suppose there would not be workmen engaged in carbonising threads?—Certainly not.

Do you find in Edison's patent any directions to workmen except the bald direction that they are to carbonise?—No; I think not.

Would not the effect of carbonising a thread of cotton or linen or fibre, such as he refers to, in a close vessel and applying great heat, without any further operation, merely be to distort or crinkle it?—Unless you fill up the space in the closed vessel in some way, no doubt the filament would be actually burnt.

Would it not require experiment and thought, and the application and some mental process for the workmen to find that out?—No experiment and very little thought.

Some thought?—No doubt some thought.

He would have to try what was the best material to use?—No; I think the quality of materials in that respect is very well known. The slightest knowledge of chemistry would tell a man that there would be sufficient oxygen in the vessel to burn that filament, and he would fill it with some carbon, I should imagine.

You do not agree that sand would do?—No; I doubt it. I think it would leave too much oxygen. It might do for a coarse filament, but for a fine filament, such as we have here, I do not think sand would do.

Supposing that a workman tried sand first?—He would find that his filament would be burnt if it was a very fine one. You might use plumbago powder.

Amongst other materials which Edison proposed to use were strips of paper?—Yes, paper coiled in various ways.

Would you say that this imaginary intelligent workman would know how to properly carbonise this strip of paper?—Yes, if he was a bit of a chemist I think he would.

Do you assume that the intelligent workman is a bit of a chemist?—Surely.

Mr. Edison did not think so, because he took out another patent a few months later for the very purpose of instructing him?—I have not looked at his patent for a very long time, and I do not remember.

Refer to his patent of 1879. Does not that contain particular directions for carbonising paper?—Yes; he tells you to pack them with tissue paper between to get them in a small space.

Sir Frederick Bramwell tells us he has seen the making of the bamboo burner?—Yes, I have seen the same in Berlin.

That Edison considered to require a patent?—I am not quite sure that he took out a patent for the bamboo fibre, but here is a patent with 44 claims, and I think it is highly probable he includes the bamboo in one or other of them.

Does not the wording of the patent of 1879 show that at that date Edison was not able to give, and therefore did not give, the necessary directions for making burners?—I certainly think he did; but it is even now an open question whether a structural carbon or one perfectly homogeneous is not better.

Was not Edison's mode of connecting the wires to smear them with putty, and then carbonise the whole thing?—Yes; my impression is that the lamp of which I have spoken was done in that way.

As to this lampblack and putty, mentioned at the bottom of p. 3 of the specification, was the lampblack to be put on before or after the material was carbonised?—I should say it would be rubbed on before it was carbonised.

What do you understand Mr. Edison to mean by saying that the resistance of fibrous material may be high or low according to the quantity of lampblack put upon it?—I understand it to mean that the more lampblack you put on the lower resistance you would get. He speaks of 2,000 ohms. If he has a burner of a higher resistance he can make it to whatever he pleases by smearing this stuff upon it.

I am told you could not carbonise fibrous material at all if it was smeared with lampblack?—I do not think that is the case.

Would it not be burnt or destroyed?—That would depend upon the dimensions of the fibrous material; and even if it were burnt you would still have the lampblack left.

Now, as to this somewhat apocryphal lamp?—It is not apocryphal to me. I saw the lamp. I have no doubt about that.

Have you ever seen a lamp made with this tar and putty?—No.

Have you ever tried the experiment whether tar and putty drawn out in a thin wire and then carbonised would produce a workable practicable filament?—No. I have never tried it myself.

Did you ever know anybody who did?—The lamp which you call apocryphal was, I was told, made in that way.

Are you prepared to say it is a useful or practicable mode?—Oh, yes, it is practicable.

Is it not a fact that an attempt to produce a carbon in this way would produce a piece of carbon that could not be lifted out of the crucible?—No, the lamp which was shown to me had not that property at all.

What is the alternative process that is employed?—The so-called Swan lamps are made from cotton thread.

Parchmentised?—Yes.

That is not in this patent?—Parchmentising is not. Edison now uses wood splints.

Treated in the manner described in the subsequent patent?—Yes, but these are merely matters of detail. He would be able to make them in the way described here.

But he does not describe it there?—He does not describe the cheapest way of making them.

Does not that make the difference between success and non-success?—No; these various improvements have brought out a number of lamps which have nothing in common except that which Mr. Edison describes.

Then the whole point is whether he has given sufficient indication to construct the present make of lamp?—I think he has; but the expression may be somewhat loose.

There are a good many loose expressions in this specification, are there?—Yes; but you can understand what they all mean.

When this burner is carbonised it would be no longer flexible?—It would be flexible, but it would spring back again.

What do you say as to oxide of zinc and camphor?—Oxide of zinc would burn at the temperature of carbonisation, but camphor might be carbonised.

The witness was examined at considerable length as to what was a filament, and he expressed his inability to define it. There was an extreme at one end which was, and an extreme at the other which was not, a filament; but when it came to the border line he could not fix any limit.

A large Edison incandescent lamp of about 800 candles was handed to the witness, but he declined to say whether the burner was a filament or not.

The principle of high-resistance lamps was known to electricians and to Lane-Fox before the date of the Edison patent?—Yes, it was known as a desideratum.

For the purpose of a single lamp there is no advantage in a high-resistance lamp?—There are one or two advantages. You can use smaller wires.

But the chief advantage in a high-resistance lamp is that you can use it in a multiple arc or a series?—In a multiple arc, but not in a series. You may use a low-resistance lamp in series, because you have not to take a large current to any one lamp.

Questioned as to Lane-Fox's provisional specification of March, 1879, in which mention was made of magnesia, zirconia, lime, steatite, and other earthy matter, witness said that in that case it was proposed to mix non-conducting material with conducting material, which would increase the resistance vastly. It would make a thicker conductor with a higher resistance.

Does not the latter part of that describe a vacuum?—Yes; but it is possible he might contemplate filling it with nitrogen.

His LORDSHIP: The principle of the high resistance of the carbon conductor was not disclosed before the date of Edison's patent?

Witness: No.

Sir HORACE DAVEY: But the scientific principles which rendered high-resistance valuable were known before?—Yes, as a desideratum.

And it was also known that in order to get high resistance you must reduce the size of your cross-section?—Yes.

The case was adjourned till the following day.

THURSDAY.

The cross-examination of Dr. Hopkinson by Sir Horace Davey was resumed.

Sir HORACE DAVEY asked if Lane-Fox's specification of his patent

Digitized by Google

of 1878, No. 4,626, did not exactly describe one of Edison's modes of making his filaments, in which he coated it with a non-conducting, non-carbonising substance, so far as the position of the burner was concerned.

WITNESS said it did, no doubt, so far as regarded the covering with non-conducting material. Lane-Fox referred to the burner as a strip or wire. He did not, however, understand that the burner was to be necessarily in the form of a strip or wire, but that was his opinion. Looking back to the specification of 1878, he agreed that the object of the inventor was to obtain a burner of high resistance, as it undoubtedly was in the earlier patent.

Is "strip or wire" one of the expressions used by Mr. Edison himself in his specification?—I think he uses the expression.

I think in the third claim he used the word filament or strip?—No doubt.

So that "strip or wire" is one of the many words which Mr. Edison uses in the course of his specification for denoting his burner?—He describes it so; but, of course, wires may be of various sections.

A little round lamp of the Edison Company was then handed to witness. He said he considered it contained a filament. The resistance of that lamp he thought from its appearance might be five or ten ohms. He would not be surprised to hear that it was only two ohms. Notwithstanding the low resistance, he would speak of the thread as a filament, as that was a term independent of resistance entirely, as used by Mr. Edison in his patent.

In the second claim he does not say anything about high resistance, does he?—No; but it runs through the whole patent.

Then you would interpolate into the second claim the words "a carbon filament of high resistance"?—Yes; I think I should.

A second lamp was then handed to the witness, who said he had the same answer to make with reference to the filament. He imagined it to be a lamp of very low resistance. He considered the two lamps in question to be made in accordance with Edison's patent. He would call two ohms low resistance. Witness did not remember that he was present at a scientific party given at the late Mr. Spottiswoode's house, in London, on 1st December, 1880, and could not, therefore, say whether on that occasion Mr. Spottiswoode's house was lighted with Swan lamps. He had been told that Mr. Edison first publicly exhibited his incandescent lamp in America in 1881; perhaps it might have been a little before that date.

It was not until some considerable time after he took out this patent of 1879?—That I cannot say.

Witness was then asked to look at the carbon of the lamp used by Mr. Swan in his lecture on electric lighting in 1879, and whether he had formed any opinion as to the way in which the carbon used in that lamp was made, and replied that he could not say.

Is there anything in the appearance of it to your practical eye which is inconsistent with its having received its present shape before it was carbonised?—No; there is nothing to suggest it.

It is very similar, is it not, to the carbons which are said to have come from Carré?—Yes. This must have been considerably changed by the passage of the current through it; so there is no telling from the appearance of it in what way it has been made.

Witness was then referred to the Cheesborough patent, and to a statement to the effect that carbon suited for electric lighting was produced in gas retorts. Witness admitted that the filaments (as Sidot calls them) formed on the side of gas retorts were formed by the same chemical process as that described in the Cheesborough patent, but in this broad sense that they were deposited from the hydro-carbon vapour upon a highly heated surface.

To put it in a popular form, it is the decomposition of coal gas coming into contact with the highly heated side of the retort?—Yes.

I do not want to call these products by any name that would prejudice them, but they are filaments in the form of little flakes?—They are described as filaments.

Mr. JUSTICE KAY: I want quite to understand—you mean that what is produced in the gas retorts is in the form of filaments?—It is the deposition as the air condenses of carbon on the surface of the retort.

Sir HORACE DAVEY: They have been called flakes?—The surface may possibly be flakey, but broadly speaking the mass is very solid and compact.

Mr. JUSTICE KAY: You are speaking of a gas retort?—Yes; of course, one has practical experience of them.

Sir HORACE DAVEY: I believe a suggestion was made for using these pieces of carbon from the sides of gas retorts as conductors in incandescent lamps, was there not?—Yes.

As long ago as the time of King, in the year 1845, a suggestion was made to use these carbons procured from the sides of gas retorts and adapted to incandescent lighting?—Yes.

What do you say to the statement made with reference to the Cheesborough patent that the heat required to produce the proper character of carbon is as high as 7,000°F.?—I should say I have very great doubt as to whether 7,000°F. is a terrestrial temperature at all. It is rather high.

You would say it is rather a large order?—Yes, most decidedly. We have no measures at all anything like so high as that.

You have no experience of heat of that kind. Probably you would not like to have?—I hope we never shall have [laughter].

But Cheesborough here contemplates that heat of that magnitude is necessary to produce the proper character of carbon, does he not?—No doubt he does.

Do you not infer from that passage that he contemplated that in his process a heat as high as 7,000°F. would be used?—He so describes it, no doubt. No doubt he had an impression that a temperature of that kind could be produced.

I want to make one thing clear. This specification does not contain any directions for gradually applying and increasing the temperature?—Yes.

I presume you will agree with this statement of fact, that as the carbon increases in size more current is required to maintain its temperature? That is known to every electrician?—Yes; but he does emphatically call attention to the necessity for it.

Sir HORACE DAVEY proceeded to read from the specification:—"Carbon pencils may be cut from this deposit (in the retort), or the original pencil with its coating may be used in the lamps." Was not Cheesborough there contemplating a process by which he could create as large an amount of carbon as he required?—No doubt.

Have you compared the description of carbon which he obtains here with the description which Deprez gives of the carbon which was the result of his process?—Yes; they are extremely alike, even in the language of description. So far as the deposition of graphite is concerned I should say they are the same. As regards the position of deposition and so on I should say they are different.

Is that because flakes were deposited by Deprez?—No; I think Deprez had referred to the electric arc.

In answer to further questions witness said that, so far as material went, the material which Deprez found in the course of his experiments, after he had wiped off the sooty deposit, was identical with the material produced by the Cheesborough process. One material might be a little harder than the other, but, broadly speaking, they were the same. The greater hardness would, no doubt, result from the better or more careful application of the process. Cheesborough did not confine his process or his material to carbon.

Have you had your attention called to this passage: "The invention is not confined to carbon alone, since it is obvious that many infusible substances, which are non-conductors of electricity, may be heated in carbon liquids or gases so as to render them conductors of electricity." Is that obvious to your mind?—No.

Is it true that you can do it?—Yes, I think you can do it. I have not tried it.

Might there be a deposit on a non-conducting substance, as, for instance, fireclay?—Yes, if you had a conductor within it.

Sir HORACE DAVEY: But would there be a deposit of carbon on a non-carbonisable substance?—Oh, yes; if you had a conductor through it so as to be able to raise to high temperature so that you could deposit carbon upon it.

You say you can get a deposit on non-conducting material—steatite, for example?—Oh, yes.

Mr. Justice KAY: If heated to a certain temperature?—Yes.

Sir HORACE DAVEY: Then suppose you took a tube of lime enclosing a pencil of carbon through which the electric current is caused to circulate, a tube of lime would be a non-conducting, non-carbonisable material?—Yes.

Did you ever try the experiment?—No.

Do you expect that you would get any deposit of carbon whatever in the lime?—I should doubt it; possibly on the surface.

Now suppose you took your pencil or rod which you thus obtained and put it into an incandescent lamp; have you ever tried that experiment?—No.

What do you think would be the effect of the great heat passing through the conductor upon the line?—It would depend, of course, upon what temperature you push it to. No doubt you could get it to work, though not efficiently, according to the standards of the present day.

Would it not have this effect—that the oxygen in the lime would combine when more heat was applied?—I do not know what the heat passing through a conductor would be, it would be very high.

Would not the effect be that the oxygen of the lime would act upon the carbon, or the carbon would act upon the oxygen, and the carbon would in a short time be destroyed altogether?—I do not think so. Of course, I am only speaking from a general knowledge, not from expert knowledge as a chemist.

You observe that in his first claim he describes his method as a method of preparing the illuminating part of an electric lamp. Do you confine that to incandescent lamps?—I have always read it so.

Witness also stated that he understood by a carbon gas or liquid, a gas containing carbon from which carbon could be deposited; broadly speaking, a hydro-carbon. But the term hydro-carbon was generally used with a somewhat broader signification. Without being enough of a chemist to speak positively, he was under the impression that at a sufficiently high temperature the necessary deposits could be obtained. With reference to prussic acid, he was not sufficiently chemist to answer.

(To be continued.)

JUDGMENT OF THE SUPREME COURT OF THE UNITED STATES IN THE TELEPHONE APPEALS.

(Continued from page 642.)

THE CONDUCT OF DRAWBAUGH CONSIDERED.

Under these circumstances it becomes important to consider the conduct of Drawbaugh in reference to his alleged invention during his twenty years of eventful history, as connected with the discovery and use of the telephone. If his present claim is true his experiments began almost as far back as those of Reis, and he had in his shop at Eberly's Mills, within three miles of Harrisburg, telephones that were substantially perfect months before Bell (on the 2nd of June, 1875) got the clue to his subsequent discovery. It is conceded that D and E, claimed to have been made in February, 1876, are substantially as good magneto instruments

Digitized by Google

as any Bell had used before December, 1881; and L, M, G, O, and H, all of which were constructed, it is claimed, between February, 1875, and August, 1876, are as good or nearly as good microphones as those of Blake, which were not invented until 1878. This is the theory of Drawbaugh's defence, as set forth in the answer and in the argument, and by it his case must stand or fall.

The claim is that the discovery of the process was complete, and that perfect telephones had been made and were in a condition for actual use a year and more before Beil got his patent.

Drawburgh was, when he gave his deposition, 54 years of age, and had lived all his life at or near Eberly's Mills, a small village near Harrisburg. He was a skilful and ingenious mechanic, and if he made D and E, and the instruments which came after them at the time it is said he did, he had good tools and good material in 1875 and 1876, and was capable of doing the best of work. He was also somewhat of an inventor, and had some knowledge of electricity. According to the testimony he was an enthusiast on the subject of his talking machine, and showed it freely to his neighbours and people from the country, whenever they visited his shop.

The Centennial Exhibition was opened in Philadelphia in May, 1876. Drawburgh visited it on 17th of October, 1876, remaining four or five days. Before he went he had heard, as he says, that some one besides himself had invented a speaking telephone, which he had the impression was on exhibition there. If what he now claims is true he had then on hand in his shop exhibits D, E, L, M, G, O, and H, all of them good instruments of their kind and capable of transmitting speech, and some of them but just finished. Bell's apparatus had been exhibited to the Board of Judges in June before, and had attracted marked attention. The matter was much discussed in the public press, and yet it never seems to have occurred to Drawbaugh to take any of his telephones with him when he went, although they were small in size, and some or all of them could have been carried without serious inconvenience. When giving his testimony he was examined in chief as to that visit, and this is what he said on the subject of telephones :—

"*Q.* Did you attend the Centennial Exhibition at Philadelphia in 1876?—*A.* Yes, sir, I did.

"*Q.* Can you give the date on which you went there?—*A.* I can by reference to a book. It was October, 1876. The 17th was a day on which I dated a letter from Philadelphia when I was there on that visit.

"*Q.* How long did your visit there last?—*A.* About four or five days, to the best of my recollection.

"*Q.* Who went with you on that visit?—*A.* Mr. George Leonard.

"*Q.* Was that the only visit to the Centennial Exhibition that you made?—*A.* Yes, sir, it was.

"*Q.* At the time you went there, or before that time, had you heard that somebody else besides yourself had invented a speaking telephone or a telephone?—*A.* Yes, sir; some time before that. I do not remember how long, but not a great while.

"*Q.* When you went there, did you suppose it would be on exhibition there?—*A.* I do not remember whether I had heard that it was on exhibition or not, but I got the impression some way that it was on exhibition.

"*Q.* While you were there at the Centennial did you see any telephones or make an effort to see any there?—*A.* Yes, sir; I made an effort and saw an instrument called a telephone and supposed it to be the instrument spoken of; the one of which I had heard. I was looking and had made some inquiry, and was directed or came to a portion of the building where I saw on a counter some man's telephone, the name I do not remember. At that time or several times that I called, there was no one there to attend to it. I spoke to another party that had something else on exhibition, I do not recollect what it was, just near by, and I asked him whether there was any one there to attend or show the instruments. I was informed then there was no one there to show them.

"*Q.* If you remember, please state what kind of an instrument it was that you saw there, and state what information you were able to obtain there regarding it and its mode of operation?—*A.* There were a number of instruments placed on to a raised portion, something like a shelf; that is, it resembled something like pigeon holes, a box open in front, and each instrument at the back of it had an electro-magnet. The number of instruments I do not remember. I do not remember counting them. If I am not mistaken there may have been a dozen or more. Perhaps some were larger than others. I cannot give you a much better description than that. I could not get any information about them. This attendant made some remarks about the instruments, but he did not understand them and could not explain them. I was several feet from where the instruments were. They were on a raised place like a shelf, just about high enough for a man to speak into. That is the way it looked to me. I did not go in behind the counter to examine them.

"*Q.* Did you see any circulars lying around there referring to these instruments or any advertisements of them?—*A.* I do not remember about that. It may have been.

"*Q.* What was your impression as to the character of the instruments when you finally left them?—*A.* I was impressed with the idea that they were instruments to telegraph by sounds, a certain sound to represent a certain letter of the alphabet. I am not certain how I got the idea, or whether any person told me that at the time, but that is the idea that I had.

"*Q.* Do you know whether that was Gray's harmonic telegraph that you saw there or not?—*A.* It did not say 'telegraph.' I am confident it was called telephone. I did not see the working parts of the interior except the electro-magnets. I took the name of the man and his address on a piece of paper, and put it in my pocket, but I do not know what became of it. I do not know whether it was Gray's harmonic telegraph or not.

"*Q.* Did you see any tuning-forks about it?—*A.* I did not."

That was all he did during his entire visit to ascertain whether anyone besides himself had actually entered upon this new and interesting field of invention and discovery. He spoke to no one about what he had done himself. He made no special effort to find out whether that which was on exhibition was in any respect like what he had at home; neither did he when he got home, as far as the record shows, say anything to his neighbours or visiting friends about what he had seen or heard. He had apparently lost all interest in talking machines.

Not so, however, with his other inventions. The testimony shows that during the early part of 1876 he was much occupied in building an electric clock, which he thought of exhibiting at the Centennial. This he did not do, however, but several days before he went to Philadelphia, or soon after, Rufus E. Shapley, a jeweller of Mechanicsburg, went on his suggestion to Eberly's Mills to look at the clock which he had made. Soon after that the clock was taken to Shapley's store in Mechanicsburg, and on the 8th of November, 1876, Drawbaugh, by an instrument in writing, transferred to Shapley a one-half interest "in the clock I am getting up, the said Shapley to pay for patenting the same." Shapley had then $2,000 in money, which Drawbaugh was anxious to have him invest in this business. The clock was taken by him to his shop so that it might be examined with that end in view, if it should prove to be useful. Some time afterwards it was taken back to Eberly's Mills, where it remained until April 1st, 1878, or thereabouts, when a clock company was formed, and this clock, or another one substantially like it, was taken about the country for exhibition. For this Drawbaugh was paid $500 and an interest in the profits.

On the 20th of September, 1878, he applied for a patent for improvements in batteries for electrical clocks. The patent was issued January 14th, 1879, to the members of that clock company. The enterprise does not seem to have been productive of any very great success.

In November or December, 1878, while this clock was on exhibition, Drawbaugh was introduced to Edgar W. Chellis. He had with him at the time a wooden model of a faucet that he wanted Chellis and another man to take a one-third interest in. An arrangement was made by which Chellis got a two-thirds' interest, he paying $250 for it January 7th, 1879. On the 14th of the same month Drawbaugh filed in the Patent Office an application for an improvement in rotary measuring faucets. After this application an interference was declared, March 27th, 1879, between Drawbaugh and David A. Hauck, who had filed an application. In his preliminary statement in this interference Drawbaugh said he had conceived the idea of his faucet in the fall of 1869, and made a working model in 1877, and the Patent Office model was not completed until about the 1st of November, 1878. The case was closely contested and finally decided in favour of Drawbaugh, January 15th, 1880. The patent was granted to him and Chellis, July 6th, of the same year. In this contest Jacobs and Hill, who afterwards became interested in the telephone claim, appeared as the counsel for Drawbaugh.

On the 2nd of July, 1879, Drawbaugh filed another application in the Patent Office for an improvement in water motors. Chellis was to have in this also a two-thirds' interest. On this application a patent was issued March 16th, 1880.

DRAWBAUGH'S CONDUCT INCONSISTENT WITH HIS CLAIMS.

It is impossible to believe, if Drawbaugh had in his shop when he reached home from the Centennial exhibits D, E, L, M, G, O and H, or even D and E alone, that he would have set himself to work in the first instance in developing the clock enterprise or perfecting his former conception of the measuring faucet, instead of calling attention to his great discovery of the telephone, which he was in danger of losing by a patent which had been issued to another, and which he could not but have known was even then attracting the greatest attention. In this connection it must be kept in mind that the theory of the defence, as stated in their answer, is that Drawbaugh had at that time fully perfected his invention, and that while at first "he conceived that its range and capacity for usefulness to the public might be very greatly enlarged," he had before the date of Bell's patent, "notwithstanding his impoverished and embarrassed pecuniary condition and his utter want of proper mechanical tools," finally perfected his work. His conduct, therefore, is to be judged, not as of one who was still in the midst of his experiments and doubtful as to the results, but as of one who had arrived at the end, and completed his success. No man of his intelligence, with or without the enthusiasm on the subject which it is said he possessed, could remain silent under such circumstances.

As we have read the testimony, it is not even pretended that he took any of these instruments outside of his own village until May, 1878, when, as is claimed, he showed one to his friend Stees, in Harrisburg, whom he had known for years, who was the first to use, and in fact was then using, a Bell telephone upon a private line of his own between his office and his shops. This produced no results, and when afterwards, in January, 1879, Chellis was told that Drawbaugh had a phonograph and a telephone that he had invented, he gave it no attention, because, to use his own language, "I was interested in the faucet and motor business, and wished to push them, and I did not think we could do much with a telephone, as Bell had a patent, and I did not know that he could ante-date it."

Again, when speaking of a conversation he had with Drawbaugh, he said, "I advised him to drop the telephone, as he could not ante-date Bell. He said he did not know about that—that he had been working on it a good while. It was his way of expressing himself when I would say, "You cannot ante-date Bell." He would say, "I do not know about that; I have been working at it a good while."

Digitized by Google

This, it must be remembered, was in 1879, after the telephone had become a success, and after it had been a year or more in use in Harrisburg, where Chellis lived. It is impossible to believe that either Chellis or Drawbaugh was ignorant of the approximate time of Bell's invention, which had been the subject of frequent newspaper comment from the time of its exhibition at the Centennial. The subject was often referred to in the Harrisburg and Mechanicsburg papers, and it is not for a moment to be supposed that all these various articles escaped their attention. Under such circumstances, if it were true that Drawbaugh had made his D and E, as is now claimed, in February, 1875, he certainly would have said so, and he would not have contented himself with so doubting an answer to Chellis's suggestion of his inability to ante-date Bell, as that which Chellis now says he gave.

Another important fact in this connection is one which is proved by the testimony of Andrew R. Keifer, who from 1863 had been division telegraph operator having charge of the middle division of the Pennsylvania Railroad, and resided in Harrisburg from 1863 to the winter of 1881. He was a member of an electric firm in that place, engaged in the manufacture of burglar alarms, instruments for the signal bureau, &c. He had also since 1876 kept a place for the sale of electrical supplies. He had known Drawbaugh since 1876, and probably before. Drawbaugh met him on different occasions in the course of their acquaintance and talked with him on electrical matters. In the course of their acquaintance, Drawbaugh showed him an electrical fire-alarm apparatus, and the working of his electrical clock, but the subject of telephone was never alluded to between them until the summer of 1881 when this occurred (we quote from the deposition of Keifer) :—

"In the summer of 1881, I took my wife out for a drive and went over to see his works, never having seen them, and having promised him to come and see him some time ; my wife not caring about going to the shop remained in the carriage, and I went through alone with Mr. Drawbaugh. He showed me through the shops and introduced me to Mr. Chellis, and showed me parts of the water-motor and some other things of his getting up. On account of my wife being in the carriage alone I did not stay long. As I stepped into, or was just in the carriage, Mr. Drawbaugh said : 'I forgot to show you my telephone !' I did not get out again to go and see it, and I drove away without seeing it, expecting to see it again, but I have never got over to the shop since."

This was after the suit of the Bell Company against the People's Company was begun, and of course after the matter got into the hands of Chellis and his associates. It is no answer to the criticism of Drawbaugh's conduct in this particular to say, as was said in the argument, that one reason why he not speak or apply to every man with whom he had a personal acquaintance was that he was ridiculed by his neighbours ; that his invention was considered a humbug by them and of no commercial value. Bell's success was proclaimed in the Harrisburg *Patriot* as early as February 26th, 1877, and the age of ridicule was then past. If Drawbaugh had at that time in his shop the machines it is now claimed were there, complete as they now are, in August, 1876, and most of them before, there cannot be a doubt that he would have taken them to some place where they could be tried, and show that they would do what he had all along claimed for them. All he had to do at any time after he came back from the Centennial was to take any pair of his little instruments to his friends at Harrisburg, attach them to a line wire, and show what he had. They were men who could appreciate the telephone and help him if it was, as he now says it was, a success. It would certainly have been easier then, within two years of the time the first of them was made, and within a year of the date of Bell's patent, to show that he ante-dated Bell, than it was three years afterwards, when he was brought into the controversy through the instrumentality of his associates, not, as must be evident to all, to get a patent for himself, but to defeat that of Bell.

In this connection it is specially significant that the application which it was claimed was made for a patent on the 21st of July, 1880, and the specification of his invention which was then written out, have been purposely and designedly kept out of the case, although their production was demanded. They were written before this suit was begun, and it is impossible to believe that they would have been withheld, at least upon the call of the opposite party, if they were in all respects consistent with the subsequent development of the case. The excuse given by counsel at the time. that they were in the secret archives of the Patent Office, and if produced and published in this case would possibly invite the filing of contesting applications and result in an interference and additional litigation, besides unnecessarily prolonging the taking of testimony and increasing the expenses, we cannot accept as satisfactory, in view of the fact that in the answer it was said that one object of filing the application "was to procure interference proceedings to be instituted against the patent of Bell, in order that Drawbaugh might be adjudged by the Commissioner to be, as he rightfully is, the original and first inventor."

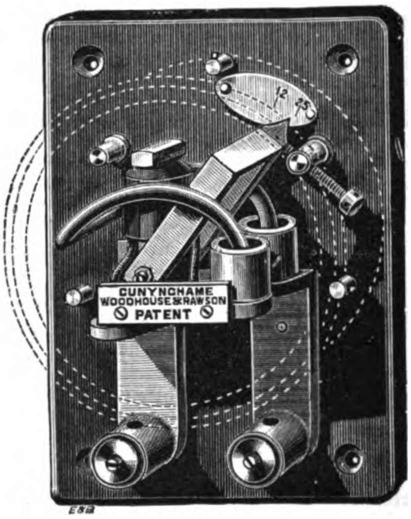
We have not overlooked the depositions that have been taken in such large numbers to show that Drawbaugh was successful with F, B, C, I and A, before D and E were made. They have been studied with care, and if they constitute all the testimony in the case it would be more difficult to reach the conclusion that Drawbaugh's claim is not maintained. But in our opinion their effect has been completely overcome by the conduct of Drawbaugh, about which there is no dispute. From the time of his visit to the Centennial until he was put forward by the promoters of the People's company, nearly four years afterwards, to contest the claim of Bell, he was silent, so far as the general public were concerned ; while if he had really done what these witnesses say he did, he would certainly have spoken. There is hardly a single act of his connected with his present claim, from the time he heard, before going to Philadelphia, that some-one else had invented a telephone which was on exhibition at the Centennial, that is not entirely inconsistent with the idea of a complete discovery or invention by himself which could be put to any practical use.

It is not pretended that what he did was done in private. He had influential friends, with ample pecuniary resources to help him in bringing out his inventions when they promised success. He easily got aid for his clock and for his faucet. The news of Bell's invention spread rapidly, and it took but a few months to demonstrate to the whole world that he had achieved a brilliant success. No one can believe that the public would be kept in ignorance of the invention until four years afterwards, when a special despatch from Washington to the *Cincinnati Commercial* announced a telephone combination to have entire charge of the telephone in this country.

(To be concluded.)

CUNNINGHAM, WOODHOUSE AND RAWSON MAGNETIC CUT-OUT.

Some considerable improvements have been lately made in these well-known instruments. The changes are principally directed towards the better insulation of the various parts and the more accurate working of the instrument. For instance, slate has been employed in the bases instead of wood. The cups which contain the mercury, and one connecting bar and terminal, are now cast solid out of copper, and the arms which dip into the cup are arranged so as to prevent any pos-



sibility of spilling the mercury. Very careful attention has been paid to the balancing and pivoting of the armature, so as to secure uniform delicacy and certainty in its movement. Messrs. Woodhouse and Rawson fit these new type instruments with a glass front cover of a circular shape, which is secured by a bayonet joint, so that it can easily be removed to replace the armature in the cups. One of the new type is shown in the accompanying illustration.

CORRESPONDENCE.

WATTMETER MEASUREMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Mr. Otto T. Blathy's letter in your issue of the 6th instant raises several points on which a little more information would be useful. In the discussion on Mr. Kapp's Paper on "Transformers," at the Society of Telegraph-Engineers, Prof. Ayrton gave on the board the following expression for the ratio of the observed watts to the true watts when the dynamometer wattmeter is employed on inductive circuits :—

$$\frac{\text{Observed watts}}{\text{true watts}} = \frac{r}{r^1} \times \frac{\tau^2 r r^1 + \pi^2 L L^1}{\tau^2 r^2 + \pi^2 L^2},$$

Digitized by Google

where r L refer to the fine-wire circuit of the wattmeter, and r^1 and L^1 to the inductive circuit under measurement. If we write T_S for the time constant of the fine-wire circuit of the wattmeter, and T_R for that of the inductive circuit, this correcting factor may be written

$$\frac{1+p^2 T_S T_R}{1+p^2 T_S^2},$$

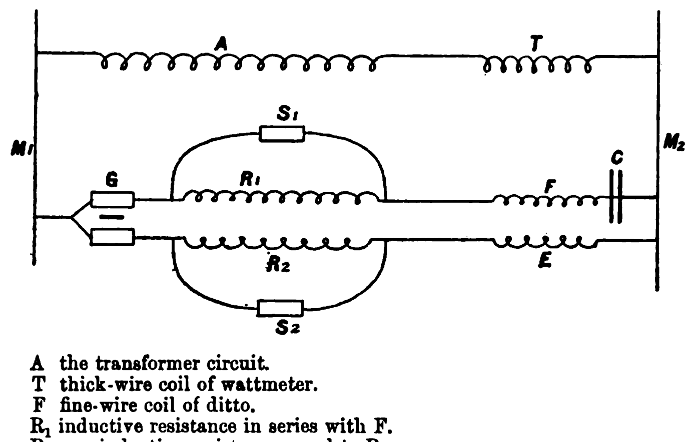
where $p=2\pi n$, n being the frequency; or when T_S is small compared with T_R, this may be written

$$1+p^2 T_S T_R.$$

In this correcting factor, as Mr. Blathy very properly points out, the time constant T_R is that of the primary circuit of the transformer as affected by the state of the secondary circuit; in other words, it is the *effective time constant* for the particular load. This will be largest when the secondary circuit is open, and least when it is loaded to its full capacity.

Mr. Blathy gives 1·000038 as the value of this correction factor for a 10 horse-power Ganz transformer run on open secondary circuit when used with a particular wattmeter. I confess I do not follow Mr. Blathy's figures when he states that the inductance of the fine-wire circuit of the wattmeter so used is ·0002 (earth quadrant ?); is that to be understood as the result of a measurement, and does it include the small inductance of the supposed non-inductive resistance in series with the movable coil ? In the case of the two horse-power transformer used by Prof. Ayrton, assuming that the calorimeter experiments are within reasonable limits of accuracy, the value $1+p^2 T_R T_S$ for open secondary circuit was found to be 1·85.

Either, then, the time constant of the fine-wire circuit, or that of the inductive circuit, is very much smaller in the one case than in the other. I cannot help doubting whether the time constant of Mr. Blathy's fine-wire circuit in his wattmeter is as small as he considers it to be. He has certainly suggested an ingenious method by which the effect of *lag* in the fine-wire circuit of the wattmeter can be annulled by the use of a double circuit, in one of which the inductance is positive and in the other of which it is made negative by using a condenser in series with half the active coil. One objection I see to this method as it stands is that it would necessitate a condenser of very small capacity, unless the resistance of the movable part of the wattmeter is made very small. Another would be found in the fact that, owing to soakage and conductance in the condenser, it would be very difficult to be sure that the value of the capacity which theory assigns as necessary was the exact practical value necessary to make the time constant of one side equal to that of the other. Another somewhat similar arrangement would be as follows :—



A the transformer circuit.
T thick-wire coil of wattmeter.
F fine-wire coil of ditto.
R_1 inductive resistance in series with F.
R_2 non-inductive resistance equal to R_1.
E ,, ,, ,, F.
S_1 S_2 non-inductive shunts, equal in value.
C condenser.
G low-resistance differential galvanometer, with soft iron needle.

The fine-wire circuit of the wattmeter F is put in series with a condenser, C, and inductive resistance R_1, shunted by a non-inductive shunt S_1. It is possible by a certain relation of the inductances of R_1 and F, and the capacity C, to make the effective time constant of the R_1, F, C circuit zero for the periodicity employed. The value of S_1 requisite may be ascertained by joining this circuit in parallel through a differential soft iron needle galvanometer with another non-inductive circuit of equal resistance, and adjusting both shunts S_1 S_2 equally until the needle of the galvanometer remains at zero. The discussion of the conditions to be obtained are rather too long to give in full. I will discuss this arrangement in some subsequent "Notes on Alternate Currents."

The most direct means to render the wattmeter an instrument of precision when used on inductive circuits will be to obtain some simple means of rendering the time constant of the fine-wire circuit accurately zero, and then the correcting factor as given by Prof. Ayrton will be always unity, no matter how large the inductance of the circuit under measurement.—Yours, &c., J. A. FLEMING.

ALTERNATING-CURRENT TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am just now studying the question of transformers with respect to the practical details of construction, and should be glad of replies to the following queries. I have read everything that has appeared in the electrical papers (including Gisbert Kapp's last paper), also Kennedy's hand-book; but, as usual, have not found the slightest allusion to the most important points of all. Take, for example, the case of a parallel distribution at, say, 1,000 volts. It is required to wind a transformer to run on above circuit, and to give an output of 1,000 watts. Supposing its efficiency to be 100 per cent., the work done in the primary coil will, of course, be 1,000 watts, *i.e.*, 1,000 volts and 1 ampere. Now, if there were were no self-induction in the primary coil, and the iron core were removed, the resistance would have to be 1,000 ohms to allow 1 ampere to pass; but it is obvious that the resistance must be very much less than this, owing to the back E.M.F. set up by the reversal of magnetism in the core and self-induction of the coil. What I require to know is simply this—what must be approximately the resistance of the primary coil, so that when the secondary coil is giving its maximum safe output not more than one ampere shall pass in the primary circuit ? What is the proportion between the current which will be produced in the primary—1st, when the secondary circuit is open, and, 2nd, when the secondary circuit is short-circuited ? With regard to the core, what is approximately the difference in the efficiency of a transformer with an open magnetic circuit (as in an ordinary induction coil), and one in which the coils are completely surrounded with iron, as in all recent transformers ? There are plenty of other points which could be easily settled by anyone having the use of an alternating current and the necessary measuring instruments. I am sure the results of such experiments would be of great interest to many other readers of this paper besides myself. I thoroughly believe myself in the A.T. system of distribution as the only practical means of distribution for central station incandescent work. The grand mistake, and one which is nearly always made by the promoter of central station schemes, is that of putting in boiler-power which is used exclusively for electric lighting or power transmission. It is obvious that it is necessary to keep the machinery ready to meet any sudden demand for increased current, and this being the case, two or three times as much coal will be burnt as is actually paid for by the consumer, especially when a meter is used. It is practically impossible, therefore, to supply the current at a price which can compete with gas. The promoters find this out when too late, and too often resort to that curse of the electric light industry, the secondary battery (as at present constructed) as a supposed remedy. By working the boilers at full steam from dusk till dawn, and drawing off the surplus steam to drive air compressors or other machinery, which can be cut off one by one as the demand for current rises, it will be found that the direct-supply system can more than hold its own, even were

Digitized by Google

secondary batteries as efficient and durable as the opponents of direct supply claim them to be.—Yours, &c.,

ELECTRICAL ENGINEER.

GLASS CONDENSERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your extract from the *Electro-technischer Centralblatt* in last week's issue, entitled "On a Glass Condenser," the author considers the result may be equally well explained on the theory of permeation of charge or on Kohlrauch's theory of polarised molecules. Doubtless some part of the effects observed may be due to the penetration of the charge into the dielectric, but the polarisation is so much greater than is usually shown by glass as to require some further explanation.

Will you allow me to suggest that the phenomena observed are due to the condenser being an accidental combination of secondary battery and condenser?

The plates of glass being somewhat porous and probably containing either moisture or some of the chemicals from which the silver coating of the plates were deposited.

The same excessive polarisation results are obtained with non-homogeneous insulators, in which a liquid conductor is incorporated. Gutta percha, for example, which is known to contain much water, behaves in this way, and so also does india-rubber, but to a much less extent.

The interposition of a more homogeneous insulating medium between the conductor and the mass of the dielectric reduces this absorption charge, and in condensers in which the dielectric is still more homogeneous, as when oil or air are employed the absorption effect disappears almost entirely.

The tests given show that the polarisation appeared to vanish at a low temperature. Probably this low temperature would coincide with the freezing point of the liquid electrolyte, with which I imagine the pores of the glass to be occupied and at which its chemical activity was suppressed.—Yours, &c.,

F. HIGGINS.

17, Cornhill, E.C., April 18th, 1888.

CONSTRUCTION OF RESISTANCE-COIL BOXES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the "Note" on the above subject in last week's issue, I have to thank Mr. Anthony for pointing out the necessity for having two connecting wires for each block in resistance boxes. He will find that I have said as much in the articles in question, the words used being, "There are two of these wires to each brass block, so that each coil is attached to its own individual pair of copper wires." Both wires are, however, not shown in the figure.—Yours, &c.,

April 14, 1888. H. D. WILKINSON.

[In connection with this subject it may perhaps be useful to remark that with bridges of the ordinary pattern in using coils of the lower denomination a still more serious error may arise, owing to the differences in the number of plug contacts which are required for different resistances. This source of error is reduced to a minimum in bridges of the dial pattern.—Ed. *E*.]

TELEPHONE INFRINGEMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The matters referred to being *sub judice*, I am unable to enter into any discussion with regard to the contents of Mr. John S. Sawrey's letter in your last issue.

I can only state that Mr. Sawyer's description of the construction of the Equitable Telephone Association's receivers attacked by the United Telephone Company is quite incorrect, and that the scope of the latter company's contentions is, as shown by documents in my possession, much wider than Mr. Sawrey apparently finds it convenient to assume.—Yours, &c.,

A. A. CAMPBELL SWINTON.

75, Queen Victoria-street, E.C., April 17th, 1888.

PHYSICAL SOCIETY.

"THE ELECTRIFICATION OF SOAP BUBBLES"

The experiments shown at the meeting of the Physical Society on the 14th inst., by Mr. Boys, on "Soap Bubbles," were exceedingly interesting and beautiful. They were designed chiefly to illustrate two points, the great difficulty with which two films can be made to unite except by the coalescence of drops of solution on their respective surfaces and the diffusion of various gases through such films. A very curious, and as yet unexplained, result obtained by the author was that the least trace of electrostatic attraction between two films was sufficient to cause their immediate coalescence.

A bubble could be forced through a wire ring of much smaller diameter than its own by the pressure of a film formed on another wire ring. A bubble could be blown inside another until the outer one was expanded to more than three times its original size by the pressure of the internal one, the outer one being obtained in a nearly cylindrical form with rounded ends to prevent contact between the lower portions which would have caused coalescence owing to contact between the two adherent drops of solution. When the inner bubble was thus pressing strongly against the outer one a large tuning fork was set in vibration in their immediate proximity, setting the films in violent vibration, but still no coalescence took place.

When, however, two bubbles resting on wire rings were brought into contact, and the smallest trace of electrification communicated to one of them, even if too small to be detected by any of the ordinary methods, coalescence at once took place.

In connection with this it is interesting to recall an experiment exhibited by Lord Rayleigh at the Royal Institution last year. Two jets were made to meet at right angles, and showed no tendency to coalescence; but this immediately took place if either of them had the slightest trace of electrification.

TELEGRAPHIC AND TELEPHONIC CHARGES: DEPUTATION TO THE POSTMASTER-GENERAL.

On Friday the Association of Chambers of Commerce waited upon Mr. Raikes with reference to the telephonic and telegraphic charges, Colonial postage, and telegraphic money orders. Sir A. Blackwood accompanied the Postmaster-General. Colonel Hill, Sir A. Rollit, Sir E. Birkbeck, Messrs. Maclean, Herbert Gladstone, Craig and Jacoby, and other members of Parliament were present.

Colonel HILL introduced the several subjects. With regard to telephonic communication, the Chambers considered that the present system, by which telephonic lines were in the hands of many competing companies, was not at all a desirable one. They felt that telephonic communication was a matter very much more considered than it was some time ago, and a greater desire existed for extending facilities for such communication; and in the opinion of the Chambers the big towns ought to be connected with each other, and that suitable "call" offices should be established in the towns, where people might avail themselves of the use of the telephone. They desired that the telephonic lines and the whole telephonic communication should be handed over to the Post Office. The transfer of the telegraphs to the Post Office had been very satisfactory, and they believed that the same result would follow from the taking over of the telephones. If this were done the Government could bring down the telephonic charges, and the largely increased business resulting would make it a paying concern. With regard to communication with lighthouses, they desired it on two grounds, viz., the saving of life and property and the convenience of navigation. As to the telegraphing of money orders, that would be a great boon.

Sir A. K. ROLLIT, M.P., said there was a very strong sentiment in reference to the cheapness of communication and the absence of telephone lines and in other ways that the country did not get the full benefit of the telephonic system. The prices for private wires charged by the Post Office were practically prohibitive. Some reductions had been made, but the scale of reduction had been very slight. With the surplus of the Post Office at about three millions there was plenty of room for liberality, especially as the resources of the Post Office were equal to the new demands which they were making.

Mr. BAYLEY (Plymouth), Mr. PLUMMER (Newcastle), Mr. WATER, and Mr. KENRIC MURRAY having spoken,

Mr. RAIKES, in reply, said that as to the question of telephones, he approached that subject with caution, owing to an imperfect report of his speech having made him say that it was the intention of the Government to acquire the telephone system of the country. He did not say anything which could fairly bear that interpretation. But if they were going to have a universal system, it

Digitized by Google

was quite plain that it must be either in the hands of one universal company or it must be in the hands of the Government. He did not imagine that any of them would ask the Government to give a monopoly of telephones to any particular company, and therefore their wishes tended towards the acquisition of the telephones entirely by the Government. But certainly this was not the most favourable moment for taking up that question with a view to action. They were familiar with the circumstances of the existing telephone companies and associations; their patents gave them something like a practical monopoly, but there would come a time when the Government would be able to treat with them on better terms than at present. He quite admitted that the telephonic system had been cramped by the conditions under which it existed, and he should be glad if any change could be made which should be satisfactory to the public. Sir Albert Rollit had told them that the prices were prohibitive. He agreed with Sir Albert; and it had always seemed to him that the charges for additional convenience, either telephonic or telegraphic, were larger than he should wish that they were; and he thought a little gentle pressure on the part of the public upon those who were the paymasters of the State might have more effect than pressure brought to bear upon himself. With regard to lighthouses, that matter was entirely in the hands of the Board of Trade. As to the telegraphic money orders, the main objection of the Government was the large balances which it would be necessary to keep at the small post-offices, and that would be a great temptation to the small postmasters. He had, however, given directions for making an experiment at Birmingham and Brighton; and if the results were satisfactory he might be encouraged to go further. The various matters submitted to him were receiving the most careful attention of the Post Office.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.—TUESDAY, April 17.

ELECTRIC LIGHTING ACT (1882) AMENDMENT (No. 2) BILL.

The EARL OF CRAWFORD, on rising to move the second reading of this Bill, remarked that he did not intend to weary their lordships by going into the former discussions upon this subject, and that the Bill was rather more extended than any previous measure relating to electric lighting. He would, however, briefly explain the changes which he proposed to introduce into the law on this subject. Under the second clause of the Bill the persons who were known as undertakers, and who provided currents of electricity for the purpose of distribution to individuals within a certain area, would be permitted to make their arrangements with the local authority as a licensing authority without having to go to the enormous delay and expense of going to a central office for a provisional order and of having that order subsequently embodied in a special Act of Parliament. The cost of the provisional order system and the Parliamentary procedure consequent thereupon was undoubtedly very high, and in addition to that there was the grave objection that that course of action could only be taken during a certain portion of the year. Unless everything was not foreseen for the next six months no work practically could be proceeded with until a new provisional order was obtained. We had to go now into a very much larger question than was contemplated in 1882 when this Act became law. In addition to the method of procedure by license, provisional order, or special Act, the present Bill would enable the local authority to enter into an agreement with, and to grant permission to, the undertakers for their several works and purposes as set forth in this Bill. In the event of the local authority refusing, the Board of Trade would be authorised to step in and to say whether that refusal was a just and a right one or not. Clause 3 went into the question of the description of the supply, and proposed that it should be given only under certain rules to be laid down by the Board of Trade. The application of electricity for lighting purposes had been in use for six or seven years, and in consequence of the demand the Phœnix Insurance Company started in 1882 a printed set of rules for the guidance of persons who were using the electric light. By carefully following those rules accidents might, as far as possible, be avoided. The rules were first published in *The Times* in May, 1882. He had made it his business to inquire whether there was any additional risk placed upon buildings which were lighted by electricity or in which the electric light was employed. He was informed by the Phœnix Office that no extra premium was charged on buildings prepared for the reception of electricity under the rules they had drawn up, even though other modes of lighting were also used. In regard to the question of safety for life, he was informed by the Pelican Office that where a building was wired in accordance with the rules laid down by the fire insurance offices they considered that there was no greater danger to life than there would be in an ordinary dwelling house. Therefore he said that the Board of Trade in framing any rules for the guidance of undertakers ought to give great weight to the rules which had already obtained during so many years, and which were drawn up by those who were thoroughly acquainted with the subject. Clauses 4, 5, 6, and 7 of the Bill were practically taken from the Gas Act of 1847, which was incorporated in the Electric Lighting Act of 1882 as far as those clauses were concerned. Those clauses contained all that was necessary in regard to the powers to be given to undertakers in taking up streets in passing from one part of a town to another. Clause 7 gave the local authority the power in all cases to do the work of breaking up the streets and reinstating them. Clause 10 was intended to give a legal status to telephones, which were now doing such valuable service, and to protect them from all possible damage by an electric lighting undertaking. He also proposed that when the undertakers were not the local authority, but a company or private individuals, they should pay a certain sum per annum to the relief of the rates for the privilege of being allowed to use the streets. He would suggest that the sum so to be paid should be £20 a mile, and in Committee—if his Bill should go into Committee—he should be prepared to state the amount which that rate would realise if London were properly dealt with. Their lordships would be surprised to learn to what an extent the rates of London would be relieved if this were done. The Act of 1882 prescribed the periods within which the works of an electric lighting undertaking were to be finished. He would propose to leave that question to be settled between the local authority and the undertaking. The next thing was that within five years from the passing of the Act all cables or wires or mains for electricity should be placed underground. Clauses 16 to 23 he had adopted from the Gas Act of 1871, and they regulated for the instruction of inspectors the methods of testing and the supply of the current to the consumer. Clauses 24 to 27 were necessarily of a temporary character, as they related to the character and quality of the supply, which at present there was no instrument accurately to test. He hoped to be able to work out in the laboratory a means of "standardising" the measurement and the current. Clauses 38 to 44 dealt with measurements, and he hoped to induce the Government to make a small addition to the Weights and Measures Act for the purpose of putting technical meters on the same footing as gas meters. In dealing with the supply to be furnished to the general public he had followed the lines of the Gas Act, 1871, so that every householder within 25 yards of the distributing mains should have a right to a current of electricity, and the undertakers should be under similar obligations to those of gas companies. He had also given the undertakers, subject to certain conditions, the power of withdrawing the supply on account of the use of a dangerous or objectionable lamp. Clause 32, also following the Gas Act, gave a local authority power to require a supply if they were within 50 yards of a current. Clause 33 dealt with the question of penalties. He did not desire to invest the electric lighting companies with any permanent monopolies; all that he asked was that they should be placed in no worse position than they were in when they first entered into their contracts. He hoped that the Bill would now be read a second time, that a great industry which had been kept back for six years since the Act of 1882 was passed would have room to exercise their capital. He knew of his own knowledge that if the law were made somewhat on the lines of this Bill that in the course of six or eight months large sums of money would be thrown into the country, and employment provided for large numbers of working men. He believed that 40,000 men would speedily be employed in preparing these works and upon the business of electric lighting. In conclusion he would only add that, in preparing this Bill, he had kept himself entirely free from any bias in favour of the electric companies, and he had endeavoured to take a fair view of what was due to the local authorities and the gas companies. He had, in fact, tried not to be a partisan one way or the other, and he trusted that this Bill, the second reading of which he begged to move, would meet with the approval of their lordships as being fair and equitable (cheers).

LORD THURLOW said, while agreeing with much which had fallen from the noble earl, he did not find himself in a position to withdraw his Bill on this subject. It was only a large amelioration in the existing law which would set the large amount of capital ready for investment free. Ever since the Act of 1882 firms and companies of electric engineers and others interested in the subject had petitioned Parliament for such modifications in that Act as would remove those restrictions which, it was alleged, had the effect of crippling the progress of electric lighting, and in a petition which was presented to their lordships' House on Monday those gentlemen had expressed a view, which he shared, that a Bill so complex in its character as that of the noble earl's stood but a faint chance of finding acceptance, if not in this House, at any rate in the other House of Parliament. Having regard to the circumstances and to the subject matter, he had no hesitation in saying that the petition embodying that view was signed by as representative and influential a body of names as could be brought together. The second reason why he was unable to withdraw his Bill in favour of that of the noble earl was that it was too soon after the great Act of 1882 to revive the whole question. All that was wanted was a simple measure of relief to the companies, giving them a larger measure of time in which to recoup themselves for their original outlay, so that they should not be compelled against their will to charge their clients a prohibitive price for the electricity which they supplied. A measure of such proportions, dealing with public questions so complicated and important, ought, moreover, to be brought in on the advice of the Board of Trade, or some other Government department, in order to do complete justice to all the interests at stake. His third objection was that it legislated on many points of detail which should be left to be dealt with by provisional order according to the merits and requirements of each case. Lastly, with regard to the purchase clauses, he objected to the Bill that it did not recognise the absolute right which the local authority should have, in his opinion, to become the purchaser on fair terms of the undertaking of a private company supplying electric light within the area of such authority.

The EARL OF ONSLOW said that the speech of the noble marquis on the occasion of the second reading of his noble friend's Bill would have shown that the Government were sincerely desirous to do what they could to promote the extension of electric lighting; and if it had been certain that the Bill now before their lordships represented the feeling of those interested in promoting electric lighting in this country, it might have deserved a more attentive consideration. But, as had been just pointed

Digitized by Google

out, a petition had been laid upon the table signed by a number of leading firms in the trade who would be most likely to apply to negotiate with the local authorities, and they were satisfied with the Bill of the noble lord opposite (Lord Thurlow). He might further say that since the Government consented to the second reading of the Bill of his noble friend opposite there had been a very large number of applications to the Board of Trade in the hope that the extension of time from 21 to 42 years would have the effect of inducing capitalists to embark money in these undertakings. This Bill proposed to make an important change in the existing law. Hitherto Parliament had declined to allow companies promoted, whether for purposes of electric lighting, gas supply, or tramways, to make their bargains for themselves without the supervision and consent of Parliament. But this Bill proposed to abolish the provisional order altogether, and the noble lord only proposed to do it in the case of the electric lighting companies. There were, he admitted, proposals in the Bill which were commendable. No doubt it would be a great advantage to secure, within a reasonable period, that those overhead wires which were a danger and disfigurement to the metropolis should be laid underground. In the Bill of the noble earl there was no provision for any penalty upon any company which failed to carry out the removal of wires. It was impossible to discuss in Committee of the whole House all the complicated and technical proposals of this Bill. Although it was true that many Committees had sat to consider this question of electric lighting, still they had not dealt with all the technical and difficult questions set out in this Bill. As he had said before, the Government were anxious to do all that they could to encourage the investment of capital in electric lighting, and although he had stated several grave objections to the Bill of the noble earl, he did not wish to throw any discouragement in the way of the increase of electric lighting. He thought, therefore, that this Bill might be allowed to go through its second reading, and then he would suggest to the noble earl that it should be referred to a Select Committee, and that on the report of that Select Committee the next stage of the Bill should be taken.

LORD HERSCHELL was glad to hear that the noble earl who had just spoken did not intend to oppose the second reading of the Bill now before them, because it involved questions of considerable interest and importance, and if some alteration were made in it it would not be inconsistent with the passing of the other Bill dealing with the subject which had received its second reading. He would regret extremely, however, if this Bill were made a ground for postponing the progress of the Bill to which he had referred, because the Bill of the noble earl no doubt raised very complicated questions which would mean minute discussion and examination, and he was anxious lest the effect would be to hang up this question to an indefinite period and prevent any legislation on the subject passing at any early date. With regard to the petitions which had been referred to, he believed that they were directed towards supporting the scheme which was already in progress rather than to opposing the Bill of the noble earl. There was no doubt that the Act of 1882, with regard to the terms of purchase, needed amendment. It was not the case that whether the terms were onerous or not was a matter affecting only the promoters and the local authority; apart from the question of whether they could make the terms such as to induce capitalists to put money into electric lighting, he thought that the public had a distinct interest in seeing that the terms were not too onerous, as the undertakers would seek to recoup themselves by charging more than they otherwise need for the electric light. That meant that the present generation was to pay more than they otherwise need for the electric light in order that the next generation might get it for less than they ought. He hoped, therefore, that the measure of his noble friend, which had already been read a second time, would be allowed to proceed. At the same time, he hoped that the Bill of the noble earl would be read a second time. Owing to its complicated character, he thought there was little chance of its passing through the other House this Session.

The Bill was then read a second time.

COMPANIES' MEETINGS & REPORTS.

The Electrical Power Storage Company (Limited).

The seventh ordinary general meeting of the shareholders in this Company took place on the 19th inst. at Winchester House, Old Broad-street, under the presidency of Sir Daniel Cooper, Bart., K.C.M.G.

The SECRETARY (Mr. Holland Dell) having read the notice convening the meeting,

The CHAIRMAN said: In addressing some observations to you before moving the adoption of the Directors' report and statement of accounts, I have first to notice that the volume of business was not as great last year as we expected, but I am glad to say that already this year a substantial increase has taken place. Our business is of a more solid character than in the past, and we direct our chief efforts to increasing the manufacturing output, as our object is not so much now to compete for large public lighting contracts. We attach, however, great importance to our installation work, and consider it to be most essential that both in the metropolis and throughout the country we should demonstrate to the public and to the electrical trade those methods and arrangements which have been adopted by our engineering department as best suited to the development and successful use of E.P.S. storage batteries as applied to electric lighting. As regards the results of the working of the year the gross profit is, as shown in the accounts, £11,875. 1s. In addition to the ordinary general expenses of management, debenture interest, &c., and the numerous charges incidental to a special business such as this Company carries on, we have allowed a very liberal provision, £1,569. 1s. 7d., for depreciation of plant and machinery, and for estimated doubtful debts, and have considered it correct to write off £1,000 from the patents account in connection with the French patents, which are now being worked in France under a satisfactory arrangement with the Company, and this sum is also deducted from the gross profit. Apart from these items it will be seen that the business about paid its way, but as we have a large balance to the credit of profit and loss we put £4,000 to a reserve fund and carry forward the balance of £6,793. 6s. 11d. We think you will consider that this policy will tend to strengthen the position of the Company, and that you will therefore approve it. The business, though unavoidably of a fluctuating nature, necessitates our keeping a staff ready and competent to deal with whatever demands may arise. Our principal branch of electrical work—the construction and working of storage batteries and their appliances—is comparatively so young an industry that we have to educate and train a staff for ourselves. I mention this in part explanation of the growth of our standing charges. There has been an increase in royalties for the past year, but I look for a much greater increase during the current year, as the result of the arrangements now completed on the Continent. The amount of patent charges, &c., of £1,080. 12s. 5d., includes expenses in connection with preparing for the patent suits alluded to in the Directors' report. The Directors are pressing on their suit against the Union Electrical Power and Light Company. Our business suffered much injury last year from the public statements of the Union Company of the superiority of their battery to the E.P.S. battery. We are always liable to sustain temporary damage by reason of so-called improved secondary batteries being brought to the notice of the public, and thus for a time shaking confidence, and causing would-be purchasers to hesitate and delay until they see what the new thing is. The general public are obviously unable to put the true value on these statements, and it requires time and labour to disprove even the wildest assertions which are put forward. We know of other batteries, some of which in due course, I suppose, will be heralded forth as marvels of excellence, but our shareholders may rest assured that these have not escaped the attention of the Directors, and these batteries, should they ever struggle into notice, will, like all the others before them, speedily disappear. The Directors considered it advisable to purchase an interest in certain outside patents, and it is necessary to take out others from time to time to cover points which may suggest themselves in the course of practical work, and these outlays have increased the amount of the patents account. Among other patents taken out are two of Mr. Sellon's, who, as you are aware, is always at work for the benefit of the Company, and who carries out all his experimental work at his own personal expense. These patents are for new forms and arrangements of batteries which, especially in the case of large central lighting stations, may prove of considerable future value. A brief record of the interesting and novel applications of E.P.S. batteries during the past year has been given in the Directors' report, and I need not here repeat them. I would, however, draw your attention to the importance for the Company of the question of central station lighting by storage batteries as against alternating-current transformers, and to the warm discussions and interest these rival systems are now exciting. The pamphlet issued by this Company on the subject was the result of much careful preparation, and is well worthy of perusal. Our engineer, Mr. King, continues his work in this particular direction. In motive power, the new electrical launch which made its public appearance at the Oxford and Cambridge Boat Race, and of which you may have read favourable notices in the electrical and other papers, embodies our latest improvements in batteries and motors, and is also fitted with special starting and reversing gear which is all quite novel. The efficiency of the motor averages 88 per cent. The best speed yet attained has been 11 miles an hour on a rather slow tide. The launch is 30ft. long, 6ft. 6in. beam, and 3ft. 6in. draught. At half speed the boat will go for 18 hours, and it is obvious that a noiseless boat of this size and speed will be useful for a variety of purposes, both for harbour and river work. The shareholders will note that the Directors are fully alive to the necessity of keeping abreast of all inventions which may conduce to the use of storage batteries, and attention is therefore being given to continuous current transformers in connection with storage batteries. We did a good deal of temporary lighting during the Jubilee rejoicings, and among our customers are His Royal Highness the Prince of Wales, the Duke of Leeds, Lord Rosebery, Viscount Stern, Mrs. Mackay, and many others. This Company lit the hall of the Middle Temple on the occasion of the dinner to His Royal Highness the Treasurer. Among the permanent installations referred to in the report may be mentioned the Bank of New Zealand, the hall of the Leathersellers' Company, the extension of the lighting at Lloyd's and at the Brazilian Bank, at Barclay, Bevan, Tritton and Co.'s; also the lighting at Naylor, Benzon and Co.'s, William Joynson and Sons, in Kent; and among private residences, that of Harry Taylor, Esq., Abraham Dixon, Esq., T. A. De la Rue, Esq, G. Newnes, Esq., M.P., and others. As regards the immediate improvements in our manufactures, I must allude to the latest form of E.P.S. battery, known as "1888" type, which has received commendation from all classes of engineers and others, as having successfully removed difficulties and objections to which some of the former types were exposed. Much credit is due to Mr. King and our electrical staff for elaborating this new type of E.P.S. battery. I am very glad to say that we have now no litigation on the Continent. Our Managing Director, Mr. Courtenay, has been obliged to make frequent trips to various parts of Europe, and has at last succeeded in terminating the law suits, and in making satisfactory arrangements with our adversaries, and, as I have already stated, we look for a considerable addition to our revenue from our Continental interests. Our friends in America, the Electrical Accumulator Company, are busily engaged in manufacturing batteries, and in developing the immense field for business before them, and are also taking steps to establish in the Courts the control for the Faure,

Digitized by Google

Swan, Sellon, and other patents they possess of the secondary battery business in the United States; and there is no one who is better fitted by his previous training to conduct that contest to a winning result than Mr. Vail, the president of the American Company. I will now conclude by stating my conviction that at no time were the prospects more favourable to the electrical business generally, and no Company is more likely to profit by its revival than we are. I beg leave to move the adoption of the report and accounts, and to call on Mr. Sellon to second the resolution.

The VICE-CHAIRMAN (Mr. J. Scudamore Sellon): I beg to second the resolution. I am free to confess that the accounts may appear somewhat disappointing to some of you. Some months ago, having in view the good work in hand and prospective orders of exceptional magnitude, my unhesitating forecast would have been that at the present moment we should have been in a position to distribute a very satisfactory dividend. What, then, are the causes of the present non-dividend position, which has perhaps tried the patience of some of you? The Chairman has lightly touched on them, and I would wish to emphasise his remarks, so that you may understand why we have good reason to look upon this position as only temporary, and be in no way discouraged by the unforeseen and exceptional obstacles which we have had lately to encounter. The first deterrent cause which the Chairman mentioned is the appearance from time to time of announcements of some new battery which is, of course, to eclipse all others, generally accompanied by the most reckless statements as to greater economy, durability, and general advantage. Such statements mislead the uninitiated, who, knowing the secondary battery is one of the important items of an installation, naturally, as the Chairman has said, hesitate to incur expenditure for any existing forms, which they are led to suspect will be immediately superseded. The stop thus put to electric lighting was incalculable, and it has been more especially marked during the last year; but this class of obstruction is now, we may hope, thoroughly thrashed out. You may, perhaps, remember that at our last meeting I took occasion to refer to a prospectus put forward about that time in which promises were held out for supplying the necessary store of energy by delivering charged cells from house to house and replacing them when required; in fact, the millennium of a perfect electric light was held out to the happy customers, who were to have no trouble and only to be subject to a low payment for the amount of electricity consumed. It is impossible to estimate the amount of injury done to your interests by these and similar wild and unjustifiable propositions, and I ask you whether my criticisms, which were much called in question at the time, were not fully justified? A year has passed, and not one single item of the enticing programme put forward with such a flourish of trumpets, and which for the time almost stopped our business, has been fulfilled. This is one example of the difficulties which needlessly have beset our path. Another, which, in my opinion, may be fraught with far more serious consequences to the public, is of a very different, and, for the moment, of a more important character; but it is being grappled with, and will assuredly prove but temporary. I alludd to the alternating-current transformer craze, for I can call it nothing else. There is, however, one satisfactory feature even in this. It evidences the fact that the public have at last realised that the electric light is a necessity of civilisation. They must and will have it, and they are now ready to avail themselves for the moment of whatever is brought under their notice, notwithstanding its shortcomings and defects. This is a great point gained, because we may feel certain that they will not be contented, once having realised its advantages, to do without it; and we may also feel quite sure that eventually no system which does not afford the highest attainable security against any possible danger or chance of extinction will be adopted. It is generally felt that, sooner or later, the lighting of theatres will be taken under the control of the Legislature. Now, is it likely that any system will be sanctioned, or even tolerated, which does not safeguard the public against possible chance of extinction of the light, which, in the absence of the storage system, may occur at any moment from the most trifling accident to the machinery in motion, to the transformer, or, in the case of overhead wires, to the leads? Conceive for a moment the effect of a sudden storm upon the ramifications of the telegraph and telephone wires crossed and recrossed by the electric light leads, carrying powerful alternating currents. Besides the incalculable damage that may be done to telegraph and telephone systems, every theatre and every public resort in London, if thus supplied, might be accidentally plunged into darkness, and catastrophes would arise as serious, though not, perhaps, so harrowing, as those which of late unhappily so often occurred through fires. I think we must accept it as being beyond doubt that reliable continuity of the electric light is essential, and that it can only be secured by the use of storage batteries. This being a condition indispensable both for the progress and the success of electric lighting their extended and ultimately universal use must be considered a certainty. This being so, you may realise what position your property, covering as it does the whole field of electrical storage, holds in connection with electric lighting, which is only, you may say, just now starting into real vitality. The distribution of electricity from centres furnished with storage batteries, is now engaging the attention of our foremost electricians, and its practical accomplishment is well within view. The objection raised by some that such accumulator depots are impracticable by reason of the multiplicity of the cells is absurd. Their ideas evidently do not go beyond the present baby type of the cell in general use, which is fairly meeting the demand up to the present time, whereas the local station accumulators of the future will consist of cells containing plates of a dimension and capacity hitherto unknown, the manipulation and working of which, of whatever size, are rendered not only possible, but free from any difficulty whatever with the improved form recently patented. I think it is hardly too much to say that from the date of the first of such centres being successfully at work the first stroke in the death-knell of the dangerous and uncertain alternating-current transformer system will be sounded. The finishing stroke will probably be the introduction of continuous-current transformers working in conjunction with secondary batteries, a system which is beginning to attract much attention, and which in the opinion of many of our best electrical experts will carry all before it. We seem thus to be on the eve of what may be called the battle of the systems. I have no fear as to the result, for independently of any question of £. s. d., the winning side must be that which proves its claim to reliability and safety, which means only those systems that adopt storage batteries. To sum up shortly the position, we have now at great cost and labour established the secondary battery on a firm basis as an indispensable and reliable factor in electric lighting. We have, as the Chairman stated, both at home and abroad secured the recognition of our rights as possessors of all the practical and useful patents in connection with this most important branch of electric work. We have, after long training, an excellent, and I think I may say a devoted staff, superintended by one whose skill and experience in our special line are very great, and who is working heart and soul in your interests, and one in whom we are thankful to feel in these degenerate days we can place perfect confidence. I allude to our electrical engineer, Mr. King. Under this combination of favourable circumstances and conditions, and having in view the development of electric work now going on by leaps and bounds, I think you must agree with me that our prospects are as good as could be reasonably hoped for. I hope that the report and accounts will be accepted, and that we may have a most successful year.

A short discussion followed, in which Messrs. Muggeridge, W. France, and J. H. Ainsworth took part.

The MANAGING DIRECTOR (Mr. John Irving Courtenay), in reply, said: I will take the remarks of the last shareholder first. You will observe that the £4,000 is not a cash balance; it is undivided net profit or book account, and therefore it is not in the form of cash, but it is to our credit. We distribute it by putting £4,000 to the reserve fund. It is not like available cash at the bank. We carry forward £6,000, which is undivided net profit. We should be very glad if it were in cash. I do not say that in that case we should have paid off the long-suffering Directors. We should be very glad to have the cash in the business, and I dare say the Directors would wait a little longer. What this Company really wants is to have large cash balances to meet our competitors and to meet the large business coming in. The Directors will be happy to consider the suggestion as to presenting some kind of interim report. As regards the gentleman who asked whether the amount owing to the Company is good, you will observe that we state "by current accounts due to the Company after providing for bad and doubtful debts." We have gone through these accounts carefully and we believe that that amount is good. I have no reason to suppose that our estimates for this year will not hold good. In regard to the question of Mr. Muggeridge, the item of £5,830 is larger than it was last year, because we have put into that item the Directors' fees, which are the same as last year, £1,500; but I may take the liberty of stating that they have not been paid any fees for the last nine months. The item is also larger than last year partly through the increase of the staff, and partly also owing to the increase in the salaries of some officers who have been with us for some time. As explained in the Chairman's speech, we are obliged to keep a permanent staff. We are compelled to train them. We do not discharge people at a moment's notice because business is slack. We would not do that, and we cannot do it. It would be very false economy for this Company to train up a staff, as we must do, from the special nature of the business, and then because the business is slack for a month or so discharge any of them. If the shareholders wish me to give any further explanation I shall be happy to do so before making some remarks on some other points; but if no one wishes to say anything else I would desire to call attention to this battle we are engaged in of batteries, &c., to one of the most salient features of our E.P.S. battery, and the point I wish to draw special attention to for the moment is the durability of the article we produce—the life of the E.P.S. storage battery. I have had lately a most remarkable instance of that. When I was in Vienna last January, I had the opportunity, owing to the courtesy of the representatives and electrical staff of the Imperial Continental Gas Association, to inspect the arrangements for the lighting of the Opera House there, in which you are aware this Company was associated. In that building there are 1,390 storage batteries of the E.P.S. type. That lighting is carried out to the entire satisfaction of the authorities. It is carried out upon the storage system with E.P.S. batteries. When I was there the cells were all, without exception, in the most excellent condition. I will now go on to allude to the most striking instance that has come under my knowledge, and I will give it as it was reported to me. The central lighting station in Vienna, belonging to the Imperial Continental Gas Association, is lighted from two batteries of E.P.S. cells. There are 53 cells in each battery. Each cell is of our largest size, containing 31 plates, so we have there 106 cells, or a total number of plates of 3,286. Those batteries have been in daily use for one year and three months, and what do you think has been the percentage of the renewals, or how many plates do you think have been renewed from these 3,286 during that period of constant use? One peroxide plate—or, as it is commonly called, positive plate—one out of the whole of that number. When we talk of the life of storage batteries I do not say that is the average, but there is evidence of independent people who have bought and paid for these plates, worked under careful and intelligent supervision. I ask is not that a commercial article? Are we not justified in practically, as we do, guaranteeing our goods at fair moderate rates? I desire to call public attention to this, because I was not aware of what had taken place in Vienna until I was there myself. I am sure it is a feature that shareholders will be glad to learn that we have now arrived at a com-

Digitized by Google

mercial stage. There is one other point that no shareholder has called attention to, and perhaps it is not wise for a Director to call attention to it as the shareholders have not done so. However, people say: "You are always taking out patents." So we are, and I wish this to go forth, that when we take out patents for improvements in batteries, covering points which have occurred to our people in practical use, we think that that money is well laid out. Mr. Sellon and the Chairman have alluded to it. When you take out a patent, as we have done latterly, for what we call our 1888 type, it is protected in this and other countries. It has this effect, it practically lengthens the life of the original or basic patents, and therefore, if so many years have gone by of your original patents, still you can keep them alive by getting out from time to time patents that you believe will be valuable and that are essential to the working of these patents. That is the policy we have adopted, and I hope the shareholders will recognise that it is judicious expenditure. I would only repeat what has been said by the Chairman, that if anything like a tithe of the inquiries that pour into our office all day come to business, we shall show this year a very different statement to what we have presented to-day. I believe now it is entirely a question of orders. We are dependent on the public and trade for orders. We are ready for the business, and we can make money when we get orders; but I desire to say, do not reproach me or the Directors next year if our expectations are not realised. We can only judge by what we see, and certainly never since I have been connected with the Company have I seen so much interest displayed and so many inquiries coming in from the country and all parts abroad, as at the present moment.—In reply to Mr. FRENCH, he added: The batteries in Vienna were manufactured at our Millwall works, sent out there, and erected by members of our staff specially sent out for the purpose. We should not, however, do that in future, because we have granted licenses to the Anglo-Brush Company, and they will be manufactured by that company's licencees under our patents, and they will pay us a royalty.

The CHAIRMAN then put the motion, and declared it carried unanimously. He afterwards proposed the re-election of the retiring Directors, Mr. Frederick Green and Mr. Sellon.

General PENNEY seconded the motion.

The CHAIRMAN: Before putting it I may say as Chairman of the Company that we may not always agree in opinion, but we work very cordially together for the interests of the Company, and I do not think there are five gentlemen in the City of London acting as Directors who give more time and attention to any Company.

The resolution was carried unanimously.

On the motion of Mr. HEYWOOD, seconded by Mr. FRANCE, the auditors, Messrs. Deloitte, Dever, Griffiths and Co., were re-elected, and the meeting terminated in the usual way.

Montevidean and Brazilian Telegraph Company (Limited).

The ordinary general meeting of the shareholders in this Company took place at the offices, 2, Tokenhouse-buildings, on the 16th inst., under the presidency of Dr. Charles Cameron, M.P.

The report of the Directors for the year ended December 31 last stated that the percentage of gross revenue receivable from the Western and Brazilian Company shows a slight increase, being £2,508, as compared with £2,370 in 1886. The Directors had hoped from the improved condition of trade with South America that they would have been able to report a more favourable result to the shareholders. They were glad to observe that, so far as could be judged from the published returns of the Western and Brazilian Telegraph Company, there appeared some prospect of a greater improvement in the traffic during the current year. The shareholders would remember that the debentures issued in 1876 were made redeemable on the 1st of July, 1896. There being a balance of £10,280 still unredeemed, it would be necessary to set aside annually a larger sum for the purpose of redemption than hitherto, and the Directors therefore propose to appropriate £1,000 for that purpose for the year 1887. That would leave a balance of £474 available for division. They recommended the payment of a dividend at the rate of 1s. per share on the Preference shares, which would absorb £415, leaving a balance of £58 to be carried forward to next account. They regretted to inform the shareholders that Sir Thomas Gore Browne, K.C.M.G., C.B., who so long occupied the position of Chairman of the Company, died in April, 1887. Mr. James Joicey, M.P. (whose interest in the Company as a shareholder was larger than that of any other gentleman), was appointed a Director of the Company, to fill the vacancy left by the death of Sir Thomas Gore Browne.

On the motion of the CHAIRMAN, seconded by Lieut.-Colonel G. W. MACAULEY, the report was adopted; and subsequently the retiring director, Dr. Cameron, M.P., and the auditor, Mr. W. S. Ogle, were re-elected.

The Eastern Extension, Australasia, and China Telegraph Company (Limited).

Report and accounts of the Directors for the half-year ended 31st December, 1887, to be submitted to the twenty-ninth ordinary general meeting on the 25th inst., at 2 o'clock:—

The gross receipts, inclusive of Government subsidies, have amounted to £232,660. 0s. 11d., against £216,956. 2s. 8d. for the corresponding half year of 1886.

The working and other expenses, including £22,730. 1s. 6d. for cost of repairs to cables and expenses of ships, absorb £69,570. 16s. 5d., against £80,066. 10s. 11d. for the corresponding period of 1886, leaving a balance of £163,089. 4s. 6d. From this is deducted £3,605. 3s. 10d. for income tax, and £41,595 for interest on debentures and contributions to sinking funds, leaving £117,889. 0s. 8d. as the net profit for the half year, which, with £35,162. 4s. 9d. brought forward from the previous half year, shows an available balance of £153,051. 5s. 5d.

One quarterly interim dividend of 1¼ per cent. has been paid for the half year, and it is now proposed to distribute another of like amount, making, with the interim dividends paid for the first half year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 3s. per share, or 1½ per cent., making a total distribution of 6½ per cent. for the year 1887. The balance of £53,051. 5s. 5d. has been carried to the general reserve fund, which, after being debited with the cost of the further partial renewal of the Singapore-Saigon and Penang-Rangoon cables, amounting to £22,758. 15s., now stands at £620,095. 13s. 6d.

In pursuance of the conditions upon which the issue was made, 113 of the Company's 5 per cent. debentures of 1880 were drawn by lot on the 16th ult., for payment at par on the 1st May prox.

276 of the Company's 5 per cent. Australian Government subsidy debentures were also drawn on the 9th inst., for payment at par on the 1st July next.

The Company's maintenance ships have been employed on various cable repairs during the half year; but no interruptions of a serious nature have occurred.

The Government of New Zealand having declined to ask the Parliament for sanction to renew the New Zealand cable subsidy, the tariff for ordinary inter-colonial telegrams was raised on the 1st January last from 6s. to 8s. 6d. per ten words. A cheap rate has, however, been granted for news telegrams between New Zealand and Australia, which appears to be generally appreciated.

A further inter-colonial conference was held at Sydney in January, when the proposals submitted by the Company for reduced tariffs between Europe and the Australasian Colonies, based upon a colonial guarantee or subsidy, were discussed, and resolutions were come to that consideration should be given to the said proposals by the various colonies, and that each colony should contribute towards the existing and future cable subsidies in proportion to population.

Your Directors have to record with deep regret the sudden death on the 16th November last of their esteemed colleague Sir William McArthur, K.C.M.G., who had been connected with the Company since its formation.

Under the powers given to them by the Articles of Association they have elected John Denison Pender, Esq., to fill the vacancy thus occasioned.

In accordance with the Articles of Association John Denison Pender, Esq., and the Most Hon. the Marquis of Tweeddale retire by rotation, and offer themselves for re-election.

The retiring auditors, Mr. Henry Dever and Messrs. Quilter, Welton and Co., also offer themselves for re-election.

Reuter's Telegram Company (Limited).

Report to be presented at the twenty-fourth ordinary general meeting of the shareholders, to be held at the Company's offices, 24, Old Jewry, London, at noon on Wednesday, the 25th April, 1888:—

The Directors beg to report that the net profits for the year ending 31st December last, after payment of current charges and deducting rebate on unexpired subscriptions, amount to £4,241. 16s. 2d., including £186. 17s. 4d. brought forward from the last account.

An interim dividend of 2½ per cent. was paid in October last, and the Directors now declare a further dividend of 2½ per cent., making a total distribution, free of income-tax, of 5 per cent. for the year. This will absorb £3,680. 8s. 3d., and after adding £500 to the reserve fund, there will remain a balance of £61. 7s. 11d. to be carried forward.

In conformity with the Articles of Association, Baron de Reuter retires from the Direction, but offers himself for re-election.

The Auditors, Messrs. Quilter, Welton and Co., also offer themselves for re-election.

The dividend warrants will be payable on the 28th inst.

The Indo-European Telegraph Company (Limited).

Report of the Directors for the year ended 31st December, 1887, to be presented to the 21st ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Monday, the 30th inst., at 12 noon.

The Company's revenue from all sources for 1887 amounted to £104,290. 18s. 3d., as compared with £104,583. 0s. 7d. for 1886, showing a decrease of £292. 2s. 4d. The expenses were—on commercial and general account, £26,274. 7s. 4d., on maintenance account, £22,346 7s. 11d., including £256. 5s. 9d. paid to the Russian Government; total, £48,620. 15s. 3d., as against £50,773. 7s. 8d., a decrease of £2,152 12s. 5d. Deducting the above expenses, taking credit for £1,093. 6s. 7d. brought over from 1886, and debiting income tax, there remains the sum of £55,194. 15s. 1d. From this amount £10,000 has been placed to reserve, and that sum, together with £10,625, amount of interim dividend, have to be deducted, leaving a balance of £34,569. 15s. 1d.

The Directors now propose the declaration of a dividend for the last six months of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent. for the year, carrying forward £2,694. 15s. 1d. to the credit of 1888.

The falling off in the revenues derived from Indian messages remarked upon in 1886, has continued during 1887, but fortunately has been made up by other sources of traffic.

Digitized by Google

Last November the Company applied the duplex system to work either of the two circuits between London and Emden; the arrangement has given very satisfactory results, and the cost of its introduction is included under the head of maintenance expenses.

Mr. C. Holland has joined the Board. The following Directors retire by rotation, and offer themselves for re-election:—H. Weaver, Esq., and A. Delbrück, Esq. The auditors, Messrs. C. F. Kemp, Ford and Co., public accountants, retire and offer themselves for re-election.

Societa Generale Italiana di Elettricita (Sistema Edison).

The Società Generale Italiana di Elettricità (Sistema Edison), operating the Edison patents in Italy, has just declared a dividend of 4 per cent. for the year 1887. The total receipts for the year were £30,493, of which £22,585 represent the income from the Milan Central Station, and £6,517. 10s. from isolated plants. The total expenses were £24,853, including £5,021 charged to depreciation account and sinking fund, leaving a net profit of £5,294, of which £4,800 will be distributed as dividends, and £494 carried forward as reserve.

The total number of lamps supplied from the Milan Station on the 31st Dec., 1887, was 11,010 incandescent lamps and 218 arc lamps, an increase over the preceding year of 1,470 incandescent and 64 arc lamps.

Seven theatres in Milan are now being lighted from the Central Station, the introduction of the Zipernowsky-Déri transformer system having permitted the extension to outlying theatres. The continued improvement in the financial results beginning with a dividend of 1½ per cent. in 1885, 2½ per cent. in 1886, and 4 per cent. for 1887, besides putting aside a large amount for depreciation (a total to date of £16,600), would seem to be full of promise for the future.

The Pilsen-Joel and General Electric Lighting Company (Limited).

Report of the Committee of Investigation appointed by resolution of shareholders at an extraordinary general meeting, held on the 13th March, 1888, to investigate the statements contained in the Directors' notice, dated 3rd March, 1888, convening such meeting, and to confer with the Directors, and to report thereon, and generally upon the business of the Company:—

The statement in the Directors' notice, dated 3rd March, 1888, that the amount of the working capital of the Company amounts to but £7,093, is taken from the last report and balance-sheet issued on the 10th November, 1887.

This sum of £7,093 is made up in such balance-sheet of the items of:—

Cash (including £2,986. 6s. Consols)			£3,037 9 0
Stock, plant, stores, &c.			3,874 0 11
and the difference between			
	Debtors to the Company	£966 3 11	
and	Creditors of the Company	784 13 5	
			181 10 6
			£7,093 0 5

As to the above item of cash, this has practically disappeared, as the whole of the Consols have been sold out, and the proceeds expended by the Directors, and the cash at the bankers at the commencement of this investigation was the sum of £140. 17s. 6d. only.

As to the item of stock valued at £3,874. 0s. 11d., this is the Directors' estimate of the value of the whole of the stock, plant, and stores, &c., of the Company.

As the three installations of the Company alone, at which a part only of such stock, plant, stores, &c., are employed, were earning, as stated in the last balance-sheet, a yearly rent of £3,485. 0s. 6d., and are now stated to be producing a gross yearly income to the Company of £5,000, it has been considered necessary to check this estimate of £3,874. 0s. 11d. by taking stock of the whole of the existing stock, plant, stores, &c., of the Company, and this has been very carefully done, with the following results, which it has appeared convenient to classify as under:—

——	Producing per annum.	Original cost to Company	Directors' Valuation.	Present Valuation.
Stock, &c., at Bethnal Green Installation	£1,200 0 0	£2,158 10 11	£416 14 7	£1,482 5 7
Stock, &c., Whetstone Park Installation	1,558 0 0	4,564 0 0	900 18 0	4,500 0 0
Directors' estimate of additions since June, 1887	—	—	2,328 5 11	
Stock, &c., at Stanhope-Street Installation	1,156 13 4	2,116 14 3	1,193 19 0	1,819 1 9
Stock, plant, stores, &c., at Stanhope-street Factory	—	3,413 19 6	1,022 0 0	2,093 9 0
Stock at Agents' and on Hire	—	—	340 9 1	340 9 1
	£3,914 13 4	£12,653 4 8	£6,202 6 7	£10,235 5 5

There has been great difficulty in arriving at the above figures in consequence of the unsatisfactory mode in which the books of the Company have been kept. There has been no stock ledger and no store ledger kept since 1884. There has been no stock book kept since 1884, except that the stock list of 1887 has been copied into a book. But the stock lists and valuations, it is stated by the secretary, have been kept separately for each of the years 1884, 1885 and 1886, and he states that such stock lists and valuations for the years 1884 and 1885 cannot be found, and they have not been produced.

It has therefore not been possible to trace or account for the stock from the year 1884, which in the balance-sheet of that year was then valued by the Directors at the aggregate sum of £29,876. 8s. 4d.

It is presumed that the shareholders do not desire to have in this report the details (which are very intricate and elaborate and can be supplied if desired), but only the results of the investigation, and in obtaining the results which are here presented to them every care has been given to make all due allowances for wear and tear and other circumstances of depreciation.

Having regard to all such considerations the value of the now existing stock, plant, stores, &c., of the Company is believed to be the above sum of £10,235. 5s. 5d.

In examining the valuation of such stock made by the Directors, it has been found that the stock, &c., has been most seriously under-valued. For example—a large number of Pilsen arc lamps in perfect order and in full working at installations, and each earning £20 yearly and upwards for the Company, figure in the Directors' valuation for 5s. 9d. each. The list price of such lamps is £12 each. The glass globes cost 10s. each. If sold by auction these lamps realise from £5 to £7 each, and the mere value of the metal if broken up and sold as scrap is 5s. 2d.

The sum of £3,874. 0s. 11d. fixed by the Directors as the value of the stock was arrived at by valuation in June, 1887, and there has been since that date certain additions to such stock, but Consols have been sold out by the Directors in the years 1887-8 which have realised £4,769. 7s. 5d.

In conference with the Directors as to the mode in which this sum has been disposed of, the only explanation given was that it had been spent upon the business of the Company, as would appear by the balance-sheet to June, 1887, and by the cash book.

To enable the shareholders to determine how far this explanation is satisfactory it has been considered necessary to prepare an analysis of the cash book, and in order that the years in which such a sum of Consols was expended may be compared by them with the years in which no Consols have been expended the analysis has been carried back to the year 1884, and accompanies this report.

The analysis is strictly compiled from the Company's cash book, and the attention of the shareholders should be directed (amongst other things) to the fact that although the income received by the Company from "Sales of Plant, &c.," has enormously decreased, the outgoings for "Rent, Rates and Taxes, Purchases of Stock, &c.," and "Wages" have varied but little comparatively. Also, that in one year £1,092. 11s. 1d. was expended in law costs, while the largest dividend paid in any year is £821. 18s. 8d. Also, that a sum of £2,500 appears in the cash book as a loan to "Ellis and Co.," and in conference with the Directors this is explained by them as having been lent to those gentlemen by the Directors with the object of obtaining 3 or 4 per cent. interest from them.

This lending of the money of the Company by the Directors to individual appears to be wholly irregular and unauthorised by the Articles of Association, and, moreover, upon investigation by the committee it is found that it was lent at an interest of 1¼ per cent. per annum only.

There also appears an item of "Contract for running new main Holborn £193. 19s. 4d.," and this was found upon investigation to be a payment to another firm of electrical engineers to run electrical wires to the Company's installations. This would seem to be peculiarly work proper to be done by the Company's own workmen instead of employing another firm to do it at a profit. In conference with the Directors, their explanation of this matter was that they thought it would be advisable, and was the best course in their opinion.

As to the statement in the Directors' notice that the item of £25,190 for goodwill and patent rights should no longer be maintained at that figure, and their intention of reducing it to £527, in conference with the Directors the following were the reasons given by them for this proposed reduction:—That the patents stood at cost price, and had only six or seven years to run, and that they were advised that if they earned profits it would not be advisable to pay dividends upon that amount. There was no data furnished for the reduction to £527, which appears to have been a purely arbitrary sum, and is given by the Directors as their opinion of value, without supplying any basis of its calculation.

In proposing this enormous reduction (as a matter of principle and apart altogether from the amount of it) the Directors have merely considered the fact that the patents are running out, and have entirely ignored the goodwill, overlooking that under good management the value of the goodwill of the business should increase in at least the amount of the diminution of the value of the patents.

It is obvious that the mere goodwill of a business which is said to earn £5,000 per annum from its installations must be worth immensely more than £527.

As to the general business of the Company, under the existing system of management it has not been, and it is not possible that it should be, worked with either efficiency or economy.

There is no proper system of check or control of stores issued. The books of the Company are not properly kept, and some of them are even now not posted since January last. The Company have obtained many orders for lighting and have left them unexecuted for several months, in some cases actually going to the expense of running the wires without fixing any lamps. There is no reserve of power at the Stanhope-street installation for any further business, and at Whetstone Park installation there is no reserve of boiler power, and the whole installation is at the risk of a breakdown from the leakage of a single tube.

The sum of £4,769. 7s. 5d. has been realised from the sale of Consols by the Directors, and spent by them during the period in which two of the three Directors were disqualified and their office vacant without any improvement in the financial position of the Company, and but for the

repayment by them since the last meeting of £200, which they had improperly paid themselves for Directors' fees, the Company would have had absolutely no money at the bank at the commencement of this investigation.

In the now existing condition of the Company, it is, of course, necessary that capital should be obtained to enable it to carry on its business properly or at all. The business, if properly managed, should be a successful and profitable one, as the system of lighting is exceedingly popular with all its customers, the number of whom might be almost indefinitely increased.

It is regretted that it has not been possible to submit this report to the shareholders at an earlier date, but the committee have not been facilitated by the Directors or the secretary in their investigation, and from the 29th March to the 4th inst. the offices of the Company were closed, the secretary absent, and the books locked up, although he had been distinctly informed that the committee desired to have access to them, and continue the investigation during that period.

During that absence of the secretary and manager, one of the installations had to discontinue its lighting of a public-house at 9:30 in the evening because at the Stanhope-street factory there were no coals.

The attitude of the Directors in regard to the investigation will appear from the following letters :—

"68, Cornwall Gardens, Queen's Gate, S.W.,
"23rd March, 1888.

"Dear Sir : I have been expecting to hear from the committee appointed at the 'Pilsen' meeting on the 13th inst., to confer with myself and my late colleagues, but hitherto I have received no communication from them. Mr. Trentham informs me that you wish to take stock. At present I do not see the utility of this, or that it comes within the scope of the resolution, but, of course, I shall be glad to hear what the committee has to say on this subject.

"For this or other purposes it seems to be in accordance with the resolution that there should be a meeting of the committee with myself and my late colleagues, and upon hearing from you I will either convene such a meeting myself or will endeavour to arrange to meet the committee with my colleagues.

"I do not read the wishes of the shareholders as expressed by the resolution to be that you or the committee should take any action at the factory or at any of the installations except in conference with me.

"I take the opportunity of informing you that the intervention of the Easter holidays and the convenience of the shareholders seemed to me to make it desirable to hold the meeting to elect Directors on the same day as the adjourned meeting (13th April). Notices will be shortly issued accordingly.

"Please communicate this letter to the committee.—Yours faithfully,
(signed) "RAWSON W. RAWSON,
"Chairman of the Pilsen Joel and General Electric Lighting Company (Limited)."

"St. Stephen's-chambers, Telegraph-street, E.C.,
"27th March, 1888.

"PILSEN AND JOEL COMPANY.

"Dear Sir : I beg to acknowledge the receipt of your letter dated 23rd, but delivered on the 25th inst.

"Neither I nor my colleagues on the committee whom I have been able to consult can accept your view as to the very limited scope of the investigation which you suggest ; but, of course, when we are in a position to do so usefully by means of the investigations we are making, we shall wish for an opportunity of conferring with yourself and the late Directors, and will ask you to be so good as to arrange it.

"I cannot but think it was a strong proceeding to delay the meeting for election of directors, when the secretary had been directed by the shareholders to send out notices *forthwith*.—Yours faithfully,
(Signed) "JAMES FYFE.
"Sir Rawson W. Rawson, K.C.M.G., &c."

Dated this 12th day of April, 1888. ANDREW HUTTON.
JAMES FYFE.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY.—The directors of this company have resolved to declare an interim dividend for the quarter ended 31st March, 1888, of 5s. per cent. on the ordinary stock, and 10s. per cent. on the preferred stock, less income-tax, payable on the 1st May to the stockholders registered on the books of the company on 10th April, 1888.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 13th, 1888, amounted to £4,649.

GREAT NORTHERN TELEGRAPH COMPANY OF COPENHAGEN.—The accounts of this company for 1887 show that, including £31,586 brought forward, the revenue was £310,802. The total expenses came to £64,798, and provision being made for interest on and amortisation of debentures, there was a balance which admitted of the payment of a dividend of 2½ per cent. in addition to the interim dividend of 5 per cent. The sum of £55,555 was added to the reserve and renewal fund, and £41,921 was carried forward, after an addition to the pension fund and directors' remuneration had been provided for. The final dividend announced for 1886 was also 2½ per cent.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 13th, 1888, after deducting the "fifth" of the gross receipts payable to the London-Platino-Brazilian Telegraph Company (Limited), were £3,787.

REMOVAL.—Mr. Julius Sax informs us that, owing to the necessity for increased accommodation in his office and show rooms, he has removed those departments to Ridgmount-street, Bedford-square, and communications are in future to be addressed as under :—Sax's Electrical Engineering Works, Ridgmount-street, Store-street, W.C. (three minutes' walk from 108, Great Russell-street).

NEW COMPANIES REGISTERED.

SOUTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED). Registered by Richard Jordan, 120, Chancery-lane, W.C. Capital £30,000, divided into 4,000 Preferred shares of £5 each, and 2,000 Ordinary shares of £5 each. Object : to carry on the business of electricians, mechanical engineers and manufacturers, and workers and dealers in electricity, motive power and light, and generally any business in which the application of electricity, or any like power is, or may be useful, convenient, or ornamental, or any other business of a like nature ; to carry on the business of manufacturers of and dealers in machines, lamps, lanterns, safety lamps and other appliances for supplying light and power by means of electricity. The first subscribers are :—

	Shares.
J. H. Aldridge, M.D., 13, Anglesea-place, Southampton	1
J. Bishop, boot manufacturer, Grosvenor-square, Southampton	1
E. G. Rose, brewer, Westwood, Southampton	1
J. Appleford, merchant, Millbrook, Southampton	1
J. G. C. E. Vanore, Lloyd's agent, Southampton	1
J. Miller, outfitter, 177, High-street, Southampton	1
E. Brown, butcher, 17, Above Bar, Southampton	1
R. Allen, 183, High-street, Southampton	1

There shall not be less than three nor more than twelve directors. The first shall be appointed by the subscribers to the Memorandum of Association. The qualification of a director shall be the holding in his own right of shares of the nominal value of at least £250. The remuneration to the directors shall be fixed by the company in general meeting.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

2,313. S. ZIANI DE FERRANTI. London. Improved means for obtaining a uniform continuous current from dynamo-electrical machines. February 15, 1888. This application having been originally included in No. 2,313, dated February 15, 1888, takes, under Patents Rule 23, that date.

5,127. J. S. GISBORNE. London. Improvements in electric telegraphic apparatus for transmitting and receiving signals on board ship or other places. April 6, 1888.

5,131. C. A. RANDALL. London. A magneto-electro storage motor. April 6, 1888.

5,162. W. M. MORDEY. London. Improvements in electric generators. April 7, 1888.

5,182. R. C. STONE and J. GILFILLAN. London. Improvements in telegraphic transmitters. April 7, 1888.

5,191. H. EDMUNDS. Streatham. Improvements in storage batteries. April 7, 1888.

5,196. M. H. SMITH. London. Improvements for conducting and collecting currents in electric rail or tramway systems. April 7, 1888.

5,201. D. H. DAVIES and J. M. TOURTEL. London. Improvements in apparatus for effecting by introduction of a coin production of electric light for a certain time. April 7, 1887.

5,233. A. H. WALTON. London. Improvements in fusible cut-outs for electrical circuits. April 9, 1888.

5,259. J. V. CAPEK. London. Improvements in electrical heating. April 9, 1888.

5,377. J. M. CROOM. Edinburgh. Lubricators actuated by electro-magnets. April 11, 1888.

5,390. J. SHERRIN and J. VAUGHAN SHERRIN. London. Improvements in velocipedes and other vehicles propelled by electricity. April 11, 1888.

5,393. A. F. ST. GEORGE and C. R. BONNE. London. Improvements in galvanic batteries. April 11, 1888.

5,421. W. ROBSON. Durham. Perpetual motion and electric current generator. April 12, 1888.

5,433. T. PREECE and T. R. ANDREWS. Bradford. Improvements in electric matting. April 12, 1888.

5,436. G. A. NUSBAUM. London. Improvements in automatic call-box for telephonic communications. April 12, 1888.

Digitized by Google

5,452. J. G. S. CUNNINGTON. London. An improved fusible device for protecting electric circuits. April 12, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the dates in italics, give notice at the Patent Office in the prescribed form of such opposition.*

April 14, 1888.

6,221. A. SHIPPEY and W. J. L. HAMILTON. London. A mode of and apparatus for governing or regulating by electro-chemical action applicable to the regulation of motors and of the feed of arc lamps, and for other regulating purposes. April 28, 1887.

6,581. E. MANVILLE and W. L. MADGEN. London. Improvements in holders for electric lamps. May 4, 1887.

7,265. C. ADER. London. Method and apparatus for phonic reception of electrical signals. May 18, 1887.

9,853. H. WATT (of the firm of H. Watt and Co.). London. Improvements relating to dynamo-electric machines. July 13, 1887.

12,017. P. L. VERCHÈRE. London. Improvements in the manufacture of carbons for voltaic batteries and certain other electrical apparatus. September 5, 1887.

633. C. COERPER. London. Improvements in dynamo-electric machines. Jan. 14, 1888.

734. J. NOAD. London. Improvements in galvanic batteries. January 17, 1888.

3,685. S. SHARP, J. M. V. MONEY-KENT and H. J. PAYNE. London. Improvements in electrical switches. March 9, 1888.

3,740. A. BERNSTEIN. London. An improved combined cut-out and switch. March 10, 1888.

PATENTS SEALED.

April 13, 1888.

3,685. R. DICK and R. KENNEDY. Glasgow. Improvements in alternating-current transformers or induction coils. March 10, 1887.

3,767. J. LEA. London. A method of checking or arresting the feed of an arc lamp and appliances for the purpose. March 12, 1887.

4,070. M. H. P. R. SANKEY and P. W. WILLANS. London. Improvements in combined engines and dynamos. March 17, 1887.

4,781. THE ELECTRICAL POWER STORAGE COMPANY (LIMITED) and H. W. BUTLER. London. Improvements in electric batteries. March 30, 1887.

4,809. E. TORTORA. Florence, Italy. Improvements in insulating electrical conductors. March 31, 1887.

17,837. P. M. JUSTICE. London. Improved means of generating electricity from heat (E. G. Acheson, United States). December 28, 1887.

17,888. G. A. SMITH. Goole. Improvements in and relating to electro-magnetic marine governors. December 29, 1887.

17,965. F. REDMOND. Dublin. Improved machines for cleaning windows, mirrors and similar articles, by either mechanical or electrical power. December 31, 1887.

SPECIFICATIONS PUBLISHED DURING THE WEEK.

4,116, 1887.—A. F. ST. GEORGE and C. R. BONNE. Electric incandescent lamps. (Price 8d.)

5,862, 1887.—W. BLENHEIM. Simultaneously driving clocks by magneto electricity. (Price 8d.)

5,958, 1887.—A. M. CLARK. Maiche. Dynamo electric, &c., machines. (Price 8d.)

6,754, 1887.—R. E. B. CROMPTON and J. SWINBURNE. Dynamo-electro machines. (Price 11d.)

6,917, 1887.—W. M. MORDEY and C. E. WEBBER. Electric transformer induction coils. (Price 8d.)

6,987, 1887.—A. SIEMENS. Electric arc lamps. (Price 8d.)

7,021, 1887.—G. SCARLETT. Electro-dynamic machines. (Price 8d.)

112, 1888.—H. F. JOEL. Incandescence lamp holders, &c. (Price 6d.)

506, 1888.—E. M. DORMAN and R. A. SMITH. Incandescent electric lamps. (Price 6d.)

ANTI-MAGNETIC LEVER WATCH.

ORDINARY WATCHES may easily become Magnetised, but such an accident was of rare occurrence until recently; but now, owing to the large number of Dynamo machines in use everywhere, it frequently happens.

The rate of the **very best Watch** will be **instantly upset** on the wearer **approaching** the neighbourhood of one of these machines.

In order to avoid this inconvenience, the **ANTI-MAGNETIC LEVER WATCH** has been brought out, which has a non-magnetic hair spring, escapement, &c. These Watches have been submitted (open and closed in every position) to the severe test of a battery of saturated bar magnets, and have not been affected in any way, keeping time without variation. They are therefore strongly recommended, more especially to **Persons having anything to do with Electricity.**

GOLD, Price £15. 0s. SILVER, Price £4. 5s. Every Watch Warranted. High-Class ENGLISH LEVER, in Stout GOLD Case, £30.

Watches securely packed and sent to any Address. Foreign orders receive the prompt and careful attention of J. N. MASTERS (Member of the British Horological Society).

J. N. MASTERS, 152, Stoke Newington Rd., LONDON, N.

ELLIOTT BROTHERS,

101 & 102, ST. MARTIN'S LANE, LONDON, W.C.

TELEGRAPH ENGINEERS AND MANUFACTURERS OF ALL KINDS OF ELECTRICAL TESTING AND TELEGRAPH INSTRUMENTS.

Submarine Mining Apparatus, &c. Contractors to H.M. Government.

SOLE AGENTS FOR THE SUPPLY OF SIR WILLIAM THOMSON'S NEW STANDARD ELECTRIC INSTRUMENTS.

Telegraph Address—"OHM," LONDON. Telephone No. 3852.

PLATINA SCRAPS,
WANTED TO PURCHASE.

W. & J. JAMIESON, 10, Broad Street, Golden Square, LONDON, W.

BROWNING'S ENAMEL PAINT,
FOR INSIDE OR OUTSIDE WORK.

Prepared to dry with an enamel surface, glossy and firm, or "flat." It has stood years of wear and washing in Drawing-rooms, Kitchens, Pantries, Basement Offices, and in Stables, Cattle Sheds, &c., especially on the brickwork of Stalls, where a hard and washable surface is essential.

It has been continuously used on the Houses of Parliament, the Eastern Telegraph Companies' system. Lines of Steamers, on Gasworks, on Hospitals, such as St. George's, St. Thomas's, &c., &c., Warehousemen and Clerks' and other Schools, Bank of England, Hurlingham Club, Metropolitan Fire Brigade, Stock Exchange, and numerous other important public works.

The Enamel Paint requires no mixing, being sent out ready for use in any colour or tint.

The **INDESTRUCTIBLE PAINT** is prepared in three colours only, Bronze-Green, Chocolate, and Black. It resists the action of acids and alkalies.

BROWNING'S COLOURLESS PRESERVATIVE SOLUTION

Is a perfect cure for Damp Walls, makes bricks and porous stone weatherproof. It has preserved the finest architecture, marble and other monuments, and public buildings from decay. It was successfully applied to Cleopatra's Needle nine years ago, and "the best authorities consider that it will have the effect of thoroughly preserving the monolith for centuries yet to come."

The Paints and the Solution secured the highest awards at each of the exhibitions, Fisheries, Health, and Inventions.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 519.—Vol. XX. FRIDAY, APRIL 27, 1888. Price 4d.

NOTES.

After remaining in a state of suspended animation for nearly four years, the International Convention for the protection of submarine cables entered into by the high contracting parties in 1884, and confirmed by a Bill in the British Parliament the year following, is to come into force next Tuesday, the 1st of May. We said of this Bill at the time that submarine cable proprietors would have been much better without it, chiefly because, although it took measures for the protection of existing cables, it made no provision—so far, at least, as these shores were concerned—to regulate the laying of fresh cables. Much, however, will depend on how the Act is interpreted; and now that the British Government is going to set up a large cabling business of its own, some fairer consideration may be given to the rights of private companies than was apparent when the Convention met.

We would direct attention to the highly valuable series of constants calculated by Mr. W. H. Preece in continuation of his recent investigations upon the relation between the fusing currents and diameters of wires of different metals. The final values arrived at are given in some tables which will be found in another column of this issue.

That famous transpontine theatre, once too well known as the "Vic," was a few years ago converted into a respectable and useful institution for the decent recreation and instruction of the South London working classes. This wholesome transformation came about mainly through the liberality of the late Samuel Morley; and it will be seen by a letter which we print elsewhere that to carry on the work the freehold of the property will now have to be purchased outright. An effort is being made to raise the necessary funds, and as the "Royal Victoria Hall" is doing excellent service—amongst other things, to the cause of technical education and science teaching—we commend the appeal to the generosity of our readers.

We cannot regard the omission of the "goodwill" principle from the purchase clause of Lord Thurlow's Bill with any degree of satisfaction. It may, perhaps, be true, as Lord Thurlow would have us believe, that "it is essential for the passage of the Bill through another place that the word 'goodwill' should not be in it." But we think it a pity to throw this sop to Cerberus before his appetite "in another place" has at least been tried. We are rather at a loss as to the construction to be placed on Lord Thurlow's remark that on behalf of the Electric Lighting Companies he was authorised to accept the omission of the term. We find it difficult to believe that the "authorisation" was in accordance with the views of the entire trade. After hearing Lord Thurlow's statement, Lord Salisbury, who at first intended to oppose the amendment, remarked that he supposed the companies knew their own business best, and therefore refrained from opposition.

If, however, the suggestion of Lord Herschell be adopted at a later stage we are inclined to think that no harm will be done. Lord Herschell very sensibly remarked that if the conditions imposed upon the undertakers were of such a character that at the end of a given term they would not get full value for their property the result would be that "the present generation would pay more for the electric light in order that, some thirty or forty years hence, the next generation should have it for less than they ought to pay." If, however, the term "goodwill" was taken to be of such sinister import that its presence would wreck the Bill, he would prefer to substitute the term "market value." We take it that this suggestion is really a clever piece of *finesse* on the part of Lord Herschell, for he is no doubt aware of the fact that by a recent decision of the House of Lords the latter term has been held to include the former. We trust that this may escape the attention of the party of confiscation.

Mr. Plunket's remarks the other evening relating to electrical communication between the House of Commons and the Library and Smoking Room appear to have been imperfectly understood, leading at least one of our contemporaries to state that such communication had been established. This, however, is not the case, all attempts at introducing the Exchange Company's automatic system, which is the one suggested to meet the wishes of members, having hitherto failed. The "majority" referred to by Mr. Plunket as being against the proposal no doubt resemble most majorities in liking not only to speak but to be listened to, and not merely to be recorded speaking "off the tape." Nevertheless, the singular fact remains that members of Parliament at their clubs are better informed of what is going on in the House than they are when at St. Stephen's itself, anywhere outside the Commons' doorway.

The report of the committee of investigation of the shareholders of the Maxim-Weston Electric Company will be

Digitized by Google

found embodied in the report of the adjourned meeting of the Company in another part of our issue. The presentation of this document and the reply of the Chairman thereon led to a prolonged and stormy discussion, and in the end an enlarged committee was appointed to pursue the investigation further. Apart altogether from the internal affairs of this Company, those who have followed its history the most narrowly will, we think, feel the least surprise at the present turn of affairs. The immediate cause of the present explosion is, however, apparently to be found in the anomalous position of the Company in respect of the "Watt" patents. These patents are not at present the property of the Company, but belong apparently to Mr. HUGH WATT, M.P., himself. Nevertheless, according to the statements of Mr. KLENCK, the development of the "invention" has been carried on for twelve months, at the Company's works, and by their own servants—a sum even appears to have been paid for "salaries" in this connection. Mr. WATT'S explanation of this peculiar arrangement, so far as we understand it, amounts to the statement that the Company would have received a *quid pro quo* in the shape of the extremely small royalty which they would have to pay the patentees on the machines manufactured. He is also perfectly willing to repay the sums hitherto expended. Now, this may or may not have been a highly advantageous arrangement on behalf of the Company, but the fact that their chairman appears to some extent to have occupied a dual position in the transaction naturally leads the shareholders to desire a somewhat more definite understanding.

THE automatic adjustment of alternate-current machines when connected in parallel has received a remarkably neat solution by Mr. SWINBURNE. His method is described and illustrated in our report of the discussion on Mr. CROMPTON'S Paper. It will be seen that it practically amounts to a contrivance for lessening the load on any machine immediately it gets out of step with the others. The load is lessened by a purely electrical device, which increases the self-induction, and therefore the lag, in the circuit of the machine. The effect is to cause a momentary tendency to race, and thus to restore synchronism.

MR. ROBERT HAMMOND'S impressive and vigorous address has certainly formed the most distinctive feature of this prolonged discussion. It was perhaps conceived in a vein to which the Society is a little unaccustomed, but if so it had at least all the charm of novelty. It must also be admitted that Mr. HAMMOND had a distinct and legitimate grievance against the author of the Paper for having spoken scornfully of the lighting at Brighton and Eastbourne. As regards the former place, our readers will recollect the elaborate description which appeared in these columns in November last, and do not need to be told that the installation is in every sense of the word a complete success, and by no means open to Mr. CROMPTON'S charge of being "confessedly carried out in a temporary manner."

BY-THE-BYE, it was before Mr HAMMOND had risen that another speaker observed that there had been "a good deal of Pears' soap business done at the Society of late." The remark is certainly justifiable; but if members of the Council are the first to set the example, how are others to be blamed for following it?

WE would direct the attention of students of alternating currents to the highly valuable Paper "On the Variation of the Coefficients of Self-Induction," read by Mr. SUMPNER before the Physical Society. The sorrowful conviction has for some time been gaining ground that the treatment of coefficients of induction as constants, and alternate currents as sinusoidal functions, may often lead to conclusions very far astray. Mr. SUMPNER, though not the first to recognise these facts, is, we believe, the first who has faced the consequences, and carried on the investigation upon these lines. *Inter alia*, it will be found that the Paper suggests a possible explanation of the recent experiments of Dr. LODGE, which show that iron is preferable to copper for lightning conductors, without necessitating the assumpt ion that iron has less self-induction than copper for high rates of alternation.

A RECENT article on the Telegraphs in China, signed J. M., in *Nature*, is interesting, chiefly perhaps for the information it affords relating to the telegraphs in Japan, with which the writer appears to have a personal acquaintance. The Japanese telegraph system, we are told, now extends to every town of importance in the Mikado's dominions. The four islands are connected by submarine cables, and the whole system with the outer world by means of the Great Northern Telegraph Company's lines. Still more gratifying is the statement that all the stores and electrical apparatus are manufactured by Japanese artisans, and that the engineering staff, as well as the operators, are educated and trained on the spot, without external or foreign aid. The lines are carefully inspected and thoroughly well maintained throughout; and the rates, although sufficiently low to bring the convenience within the reach of all classes, are remunerative to the Japanese Government, to whom of course the local telegraphs belong.

BUT, turning to the writer's main purpose, which is to show what might be accomplished in the empire of China, the natives of which are as intelligent and as skilful as those of Japan, and the ground to be covered eighteen times larger, we are met by some contradictions that leave the immediate prospects of telegraphy in the Flowery Land as uncertain as ever. The writer's chief anxiety seems to be to get the lines erected at once "almost in any fashion, so long as they can be made to convey a message, if even, as is most probable, the entire system has to be reconstructed at a no distant date." His first aim is "so to familiarize the natives with the aspect of the intrusive posts and wires that they will combine to protect rather than destroy them." Yet we are assured further on that, whereas in Japan the people were hostile and the Government friendly to the telegraphs, in China the reverse is the case, the people being friendly, and the Government, until recently, hostile. Then follows the warning that "it will be better not to construct the lines (in China) at all," unless they are adequately maintained in "efficient working order," lest public confidence in the innovation should be shaken. How the Chinese are to be

Digitized by Google

familiarized with the poles and wires, regardless of their stability, and convinced of their efficiency at one and the same time, is not explained. If the natives of the interior are not going to meddle with them, the wires might as well be erected permanently in the first instance.

THIS week's issue of *The Electrician* consists of 72 pages, and is accompanied by a presentation steel-plate portrait of Sir JOHN PENDER, K.C.M.G.

The Electric Light in China.—The Chinese Governor of Tamsui has had his palace lighted by electricity.

The West Indian Cable.—It is announced that the cable between St. Vincent and Barbadoes is now repaired.

The House-to-House Electric Lighting Company. — We understand that Mr. A. P. Trotter has severed his connection with the above company.

Birmingham.—The banking premises of Messrs. Lloyds, Barnetts and Bosanquets are being supplied with electric light. The installation will consist of fifty lamps.

The Gaulard-Gibbs Transformer Patents.—It is announced that the Gaulard transformer patents in France have been acquired by a powerful syndicate, at the head of which is the Banque d'Escompte.

Electrical Music.—A provincial paper states that "Signor Bozza" has invented a new musical instrument, playable only by electricity; it is made of porcelain, "and from it he produces music quite unique in sweetness and penetration."

Boulogne.—Some 700 incandescent and 30 arc lamps have recently been installed in the Casino at Boulogne-sur-Mer, the arcs being intended to light the gardens. Two 100 horse-power Edison dynamos furnish the necessary current. The installation has been carried out by the Edison Continental Company.

Central Station Lighting at Bremen.—The contract for providing a central electric light station at Bremen has been awarded to Messrs. Spiecker and Co., of Cologne, whose tender amounted to £30,000. We believe that several English firms sent in tenders. A large number of accumulators will be employed in this station.

Cairo Telephone Company.—Owing to the very severe conditions imposed by the Egyptian authorities, the request of the Cairo Telephone Company to be allowed to run a wire to Alexandria has had no result. The *Bosphore Egyptien* understands that the Government will shortly undertake the matter itself. The Van Rysselberghe system, utilising the existing telegraph wires, will be adopted.

Transmission of Power in Italy.—The factory at Oerlikon (Switzerland) has entered into negotiations with a large Milan firm to erect an installation capable of transmitting 250 horse-power a distance of about 600 yards, with a guaranteed yield of 78 per cent. The motive power is to be furnished by turbines driving two Oerlikon dynamos, the current being transmitted to the two motors in the factory by three wires, as at Kriegstettin.

The Effect of Air Pressure on Radiation.—M. Cailletet has conducted a series of experiments which show that the heating effect of a current on a piece of platinum wire is proportionately diminished as the pressure of the air around such wire is increased. The converse has long been established. M. Cailletet has shown that a current which would fuse a wire under ordinary pressure will scarcely raise it to redness when the pressure is sufficiently great.

Simla: Lighting the Viceregal Lodge.—Arrangements have been made for lighting the new Viceregal Lodge at Simla by means of electricity. This work has been entrusted, as regards the electrical apparatus, to Messrs. Siemens Bros., London, and will in all probability be completed before Lord Dufferin takes up his residence at Simla for the hot weather. His Highness the Maharajah of Bhownuggur has also ordered an installation of electric lighting for one of his palaces. Messrs. Siemens Bros. and Co. are supplying the whole of the plant for this installation also.

The Electric Light on Ships.—In the course of his remarks at the general meeting of the Royal Mail Steam Packet Company, on Wednesday, Mr. Eden Colvile (the chairman of the company) said:—"We have put the electric light into twelve of our ships, and from the experience we have had, from what we hear from the passengers generally, that is exceedingly judicious expenditure. It is a very favourite light among the passengers. It is a much safer light, I think, as against fire than burning oil lamps or candles. I cannot say it is a saving in expenditure actually, but we feel the effect in the increased numbers of passengers we carry, to whom it gives great satisfaction."

Liverpool.—An "International Brewers', Vintners', and Industrial Exhibition" is to be opened at New Brighton early in the ensuing month. The contract for the electric lighting has, we understand, been entrusted to Messrs. Hills and Thomson, of Liverpool. Both arc and incandescent lamps will be used, including some of the high candle-power "Sunbeam" incandescents. Messrs. Hills and Thomson have been introducing the "Sunbeams," with great success, for ship lighting, having recently fitted them in, amongst others, the Atlantic liner the "City of Rome," in place of the arc lamps formerly in use in the engine rooms, and for cargo lights. There is doubtless much to be done in this direction.

Kensington Vestry.—The Works Committee of the Kensington Vestry have reported that they have again considered the application by the Kensington Court Electric Light Company (Limited) for permission to open the footpath in parts of Kensington High-street for laying wires, and a proposal for running wires in a portion of the route through the sewers; and recommended that permission be granted on condition that the work is carried out at night in places where interference with trade, &c., would otherwise result; and that it be executed to the satisfaction of the vestry's surveyor.—Mr. Braye moved that it be referred back for the Works Committee to reconsider.—Mr. Oliver seconded, and this was carried.

Search Lights in the Navy.—The mimic naval operations of last year and the more recent tests of the value of the defences of Malta, when attacked at night by vessels equipped with powerful electric search lights, have conclusively demonstrated the utility of the electric light in all naval operations conducted under the cover of night. An order has now been issued that every vessel in the British Navy is to be so fitted, provided that the boilers are in a sufficiently good condition to admit of the requisite pressure being maintained, and no ship is to be constructed in the future without provision being made for at least four search lights. An officer specially appointed will supervise all electric fittings in ships of war dealt with in home dockyards.

The Electric Light in Italy.—During the month of February the Terni Central Station has been opened. It has a capacity

Digitized by Google

of 3,000 16 candle-power lamps, the plant comprising three groups of machines, each group consisting of a 150 horse-power Girard turbine, a 2,000-volt 40-ampere alternate-current dynamo, and an exciter. The station is outside the town, 200 metres from the walls. The current is distributed by means of 21 Zipernowsky transformers, each of 7,500 watts capacity, the difference of potential at the secondary terminals being 100 volts. In addition to private consumers the light is supplied to the town, 350 lamps of from 10 to 50 candle-power being charged for at from 4 to 13 centimes an hour. All the wires are bare, and run overhead.—The electric light has also been introduced to a Avellin and Omegna, the station at Avellino being capable of supplying 2,500 incandescents.

Mexico and Cable Extensions.—Reports have been circulating in Mexico to the effect that English capitalists had under consideration a project to lay a cable between London and Havana, with the intention of extending it to Yucatan, the most eastern State of Mexico. A correspondent of a local paper writes that he has ample authority for stating that any such project would be utterly impossible, for some years to come at any rate, seeing that the "sole concession for laying, working, and maintaining an ocean cable at Havana has already been granted to the Cuba Submarine and the International Ocean Telegraph (International Cable Company, Limited ?) Companies of London." The Mexican paper further states that the Government, by its concession with the Central and South American Cable Company of New York, is debarred from permitting any further competing company to land and operate a cable in the State of Yucatan.

St. James's Vestry and the Electric Light.—As reported in our last issue, the St. James's Vestry, after some discussion, adjourned the consideration of their position with regard to the St. James and Pall-mall Electric Lighting Company, who are applying to the Board of Trade for a license for that district. At a meeting of the Vestry on the following Thursday, Mr. John Bonthron presiding, it was agreed, however, to support the application. The draft license follows the lines of the South Metropolitan Electric Lighting Order, but with two additional clauses—one providing that the Vestry shall not withhold consent to overhead wires during the first three years of the license, and requiring the company to remove all such wires on the expiration of the three years, or at any time required by the Vestry; and the other authorising the company to apply for a provisional order at the expiration of two years. The area of supply is the parish of St. James, Westminster, the compulsory area being so much of the parish as lies south of Burlington-gardens, Vigo-street, Glasshouse street, and Tichborne-street, and the optional area the remainder of the parish.

Electricity in Medicine.—The *Medical Press* writes on this subject as follows :—"If electricity continues to make its way as a therapeutic agent as it has done during the last few years, a working knowledge of the science will soon become indispensable for the general practitioner. Even now, while its therapeutic value is still, to some extent, *sub judice*, its aid in the diagnosis of certain nervous affections could not very well be dispensed with. Yet it must be confessed that only a small proportion of medical men know enough about it to be able to use it to advantage for either diagnosis or treatment. Very few could name the different varieties of currents, still less their particular properties, and, as the recent discussions on Apostoli's treatment have shown, the dynamic value of currents of specified strengths is a mystery even to those who use them. A knowledge of medicine, to be trustworthy, involves a certain familiarity with the sciences, and this is a department which is to a large extent ignored by other than University Examining Boards. It is to be hoped that this, among other shortcomings, will be remedied in any future scheme of medical education."

Electric Light Signalling by Reflection from Clouds.—In our issues of November 18th and December 2nd we referred to the successful experiments which have recently been made in signalling over great distances by means of flashing from arc lights upon the clouds. In continuation of this series of experiments further trials have recently been carried out at Simon's Bay. The experiments were conducted under the direction of Admiral Sir W. Hunt-Grubbe, K.C.B., commander-in-chief. The telegraph wire to Cape Town was supposed to be destroyed, and an electric beam of 100,000 candle-power was directed against the clouds in a series of interrupted flashes, after the manner of a heliograph. It was found that the messages could be read easily at Cape Town. Experiments were then made by a vessel of war from a greater distance at sea, with general success up to a distance of fifty miles, when a change in the conditions of the atmosphere occurred, and the signals could no longer be read. It has been established, however, beyond doubt that this method of flashing signals from hitherto undreamt-of distances is possible, but only under favourable atmospheric conditions.

Train Telegraphy.—The practical value of the system of induction telegraphy on moving trains was well illustrated, says the *Scientific American*, on the Lehigh Valley Railroad during the recent great snowstorm. "In the accident near Three Bridges the train telegraph operator at once telegraphed back to Flemington for a wrecking train. Within a short time Superintendent Donnelly arrived, and during the entire day messages were sent to and from the wrecking train, and surgical relief was obtained. All the beleagured passenger trains, every one of which was equipped with the new system, were located by means of train telegraphy, and provisions were sent to the hungry passengers. Belated passengers sent despatches to anxious wives from the various stalled trains, and all the manifold business of railroading was carried on with celerity. More than 200 messages were sent back and forth over the single line of the company during the three days of delay. The poles used to carry the line are only 16ft. high, and they expose little surface to the storm. The messages are transmitted by induction from the metal roof of the car to the line, a distance of 10ft., and even when cars and line were both buried in the drifts no inconvenience was suffered, as the dry snow acted as a good insulator."

Severe Thunderstorm in Scotland.—The *Glasgow Herald* says :—"A thunderstorm of some severity, accompanied by heavy showers of rain, passed over a considerable portion of Scotland on April 19th. Our Perth correspondent states that the storm was the most severe experienced in that district this season. The flashes of lightning were particularly brilliant, and rain poured in torrents all the afternoon. In Forfar several peals of thunder, evidently at some distance, were heard between twelve and one o'clock, and a few drops of rain fell. The weather, however, cleared a little until two o'clock, when the sky got densely overcast. Two or three very strong and vivid flashes of lightning, followed by tremendous peals of thunder, took place. A flash of lightning struck one of the telephone wires near the central office in Castle-street, rendering it useless for the night. Fortunately no one was hurt, though the officials and some people in the streets were very much startled. A very heavy downpour of rain was expected, but the shower that followed the thunderstorm was comparatively light. At Ayr the lightning was very vivid, and the

Digitized by Google

flashes came in close succession. Between one and two o'clock the thunderstorm approached Johnstone from the east and passed over the town. There were some half-a-dozen flashes of lightning, accompanied by peals of thunder."

Portable Electric Lighting Plant for the Austrian Army.—In March, 1887, Messrs. Ganz and Co., of Buda-Pesth, constructed some portable electric lighting plant for the Hungarian State Railways, the plant being required for the purpose of facilitating the "entraining" and "detraining" of troops during the night. This plant was used on two occasions with very satisfactory results during the last autumn manœuvres on the Roumanian frontier. The plant comprises an ordinary eight horse-power portable engine, upon which is fixed a Zipernowsky alternating-current dynamo capable of running eight Zipernowsky 600 candle-power arc lamps. A car somewhat like a furniture van contains the lamps, the masts, a cart with two drums upon which are rolled 2,000 metres of wire, ·003m. diameter, and all the apparatus for erecting the circuit, in addition to two water tanks for the engine. Both engine and van can be easily placed on trucks and taken by rail to their destination. The operation of unloading is easily performed at railway stations, and when it is necessary to unload in the middle of the line two U-pieces are used. The installation can be completed under the direction of an engineer in seven hours, and taken down in five hours. The cost of the eight arcs for ten hours amounts to 17fr. 50c. The whole plant costs about 21,000fr. (£840). Messrs. Ganz and Co. are negotiating with other railway companies with a view to supplying similar plant.

Rouen.—The Thomson-Houston Company have put up nine 1,200 candle-power arc lamps in M. Désiré Giron's factory at Rouen, the power being furnished by a waterfall nearly a mile distant. For a few hours every evening a special circuit is run in two large hot-houses, enabling the members of the Rouen Horticultural Society to experiment with the influence of the electric light upon plants. The offices of the *Patriote de Normandie* will soon be lighted by electricity, the plant comprising a Powell gas engine, a small Thomson-Houston dynamo, and a set of accumulators. The Church of St. Ouen, on the Place de l'Hôtel de Ville, is also being fitted with one hundred 2,000 candle power arc lamps, and a 350 incandescent light chandelier. The Rouen Municipal Council has received several tenders for the lighting of the theatre and town library. No decision has yet been arrived at. The proposed installation is to consist of two 1,000-light Thomson-Houston dynamos, one 500-light dynamo, one 25-arc light dynamo, and a large battery of accumulators; the whole to be driven by Armington and Sims engines. MM. Condors Brothers are about to erect a Thomson-Houston central station at Rouen, and already 2,700 applications for 9,500 incandescents and 1,200 2,000 candle-power arcs have been received. The negotiations with the authorities in this matter are based upon a tax of 25 per cent. on the gross receipts and the installation of the light in all the streets traversed by the subscribers' wires. The wires are to be run overhead on iron posts.

Glasgow Exhibition.—There will be a very fine display of electric light at the Glasgow International Exhibition, comprising 559 arc lamps and 750 incandescent lamps, exclusive of the powerful arc lamps used in connection with the fountains. The Anglo-American Brush Corporation supplies 519 arc lamps, Messrs. Thomson and Houston supply 40 arc lamps, Messrs. King, Brown and Co., of Edinburgh, are responsible for the incandescent installation, and Messrs. W. and J. Galloway and Sons provide the fairy fountain plant. The engine and dynamo room is of ample dimensions, with an overhead gallery for those who desire to see the machinery in motion. The Brush plant comprises nine 35-light and ten 25-light dynamos, the power being derived from no less than seven engines made by four different firms; this plant lights the main portion of the building and all the grounds. The Thomson-Houston installation consists of four dynamos, driven by two vertical engines, the lamps supplied by this firm being placed in the picture gallery. Messrs. King, Brown and Co. have four dynamos, run off two Westinghouse engines, their plant being used to light the refreshment and dining rooms and some of the smaller courts. All the electrical arrangements of the Exhibition have been under the superintendence of Mr. W. A. Bryson. We may add that the main shafting in the dynamo room is divided into sections, the large engines actuatin; the separate sections by means of rope gearing, the pulleys being the "differential tight-grip" pulleys of Messrs. Weyman and Johnson, of Guildford.

The Crystal Palace School.—On Saturday Mr. John Aird, M.P., Assoc. Inst. C.E., presented to the successful students of the Crystal Palace Company's School of Practical Engineering the certificates which have been gained during the term just ended. The school includes a course in electrical engineering, for which a well-equipped laboratory is provided. Mr. Aird reviewed in very favourable terms the work carried on in the several offices and shops of the school, and made some interesting remarks upon his own early associations with the Crystal Palace. He reminded the students that the Crystal Palace itself was a great engineering work, and told them much about the water towers and the hydraulics of the fountains, with which he had been personally concerned. He related how, when the north tower was nearing completion, Mr. Thackeray expressed a wish to ascend it, which he did, by means of ladders, to about half its altitude, when, his nerve failing him, he had to be carefully lowered to the ground. Mr. Aird adverted to the excellent results that were obtained from the work of the school; expressed, as a large contractor, his satisfaction with the specifications the students had prepared, and adjured them to work earnestly and steadfastly. Votes of thanks were passed, on the motion of Dr. Read, to the examiners, Mr. R. Hodson, M.I.C.E., M.I.M.E., and Mr. A. E Preston, A.M.I.C.E., F.G.S., &c.; and to Mr. Aird, on the motion of Major Dickson, M.P., chairman of the Crystal Palace Company. The report was read by Mr. Shenton, superintendent of the Educational Department; and Mr. Wilson, Principal of the School, made some remarks to the students.

Equipment of the Paris International Electric Laboratory The Paris International Electric Laboratory is a one-story building, and the various departments are equipped as follows:—The machine room contains a 20 horse-power Otto gas engine, and connected with it by a counter-shaft is a 20 horse-power steam engine, placed in the yard. The electric machines are a 70-volt, 300 ampere, constant-current Gramme dynamo, an alternating-current Gramme dynamo, and 100-light Edison dynamo, connected with which are two switch-boards, one for the constant currents and the other for the alternating. The photometric room contains a large Bunsen photometer, with a 13ft. scale and the accompanying standard lamps, and a Dumas and Reynault balance for weighing the consumption of oil. The electro-chemical laboratory is equipped with a large number of instruments for obtaining measurements of the electric current by the deposition of silver and other metals, a subject in which the superintendent, M. de Nerville, acquired extensive experience in connection with the determination of the legal ohm. The calibrating room contains standard mecurial resistances, three Deprez-d'Arsonval

Digitized by Google

galvanometers, and one Mascart electrometer. The testing of commercial ammeters and voltmeters belongs to this department. The cable testing room contains a full supply of apparatus, comprising Wheatstone bridges, Thomson mirror galvanometers, Deprez galvanometers, a Carpentier dead-beat electrometer, and a Leclanché 100-cell battery. In the main hall are two Thomson graded galvanometers, a small hand Gramme dynamo, a Wimshurst induction machine, a Gaulard and Gibbs transformer, and a 1 horse-power Gramme motor, driving a Romilly pump. This hall is to be used for conferences and special experiments.

Magnesium.—Magnesium is a metal which is perhaps destined in future to play a more important part than has hitherto been supposed. The *Journal* of the Society of Chemical Industry says that the rolling of magnesium does not offer the slightest difficulty, even such complicated forms as T I U, or as angles, round or four-cornered rods, plates or sheets of 0·1mm. thickness. And as pure magnesium is sufficiently resistant to atmospheric influences and can be polished and easily cleaned, it lends itself on account of its lightness and relative strength to the construction of apparatus, &c., required to be made of metal and also to be light, as, for instance, nautical, physical, and astronomical instruments. The working of magnesium requires heat. At a temperature of 450° C., it can be rolled, pressed, worked, and brought into complicated forms. Screws and threads can be made of magnesium, and these are considerably sharper and more exact than those from aluminium. Owing to its cheapness, magnesium can also be used in the manufacture of a variety of useful articles. Experiments in this direction are now being made. The following experiments were made for the aluminium and magnesium manufactory in Bremen, at the mechanical experimental station in Charlottenburg. Tensile strength, limit of breaking, 23·2 kilos. per 1 qmm., specific resistance to compression 27·2 kilos. per 1 qmm., bending strength 17·4 kilos. In comparison with other metals the strength of magnesium is relatively very considerable. The breaking coefficient for tensile strain per square millemetre is :—

		Specific gravity.
Magnesium.....................	23·2 kilos	1·75
Aluminium.....................	20·5 „	2·67
Brass	12·5 „	7·8-9·5
Bronze	23·0 „	8·9
Rod iron......................	38·0 „	7·6-7·8
Delta metal, poured in sand..	34·36 „	8·6
Delta metal, rolled hard ...	53·0 „	—

Exeter.—The Mayor of Exeter (Mr. C. T. K. Roberts) presided over a private meeting of the Town Council at the Guildhall, last week, convened for the purpose of considering the advisability of lighting the city by electricity. The proceedings having been formally opened by the Mayor, an interesting and at times lively discussion ensued, a large number of members being in favour of recommending the adoption of the electric light as an illuminant of the main streets of the city, whilst others opposed it chiefly on the ground that it would be unfair, in the face of existing burdens, to load the ratepayers with the cost of an experiment which might after all turn out a failure. Mr. Massingham, the agent of the Thomson-Houston system, with which the main streets of the city have been lit for some months, was called in, and, in answer to questions put to him by the members, stated that he was prepared to light a quarter of the city from St. Anne's Chapel to Exe Bridge, taking in Queen-street, Bedford-circus, Fore-street, South-street, North-street, and Magdalen-street, with forty arc lamps, which together would give a light equal to 48,000 candle-power, for £800 a year, £20 a year for each lamp. The light would be kept on about ten hours a day, from dusk to daylight. He pointed out that the area he had mentioned was at present lit by 207 gas lamps, which gave a light of about 3,700 candle-power, and cost £809. 7s. 4d. per year.—Several Councillors, while admitting that the electric lamps would have about fourteen times more illuminating power than the gas lamps, were of opinion that they would prove to be inadequate, as they would have to be placed so far apart from each other.—A resolution was proposed and seconded to the effect that in consideration of the present financial state of the city the committee recommended that the proposal to light the city by electricity be not adopted. To this an amendment was proposed to the effect that the various electric lighting companies be invited to inform the committee the price at which they would be prepared to make an installation for the purpose of lighting the city. On being put the amendment was carried by a majority of about half a dozen. A rider was then proposed to the effect that in the event of the price of electricity not being greater than was at present paid for gas the committee recommend to the council the adoption of the first-named illuminant. This was carried *nem. con.*, and the proceedings terminated.

The South Metropolitan Electric Light Company.—A special meeting of the Commission of Sewers was held at the Guildhall last week, to consider a letter from the Remembrancer relative to the application of the South Metropolitan Electric Light Company to the Board of Trade for a provisional order. Mr. W. H. Pannell, who presided, said the Remembrancer would read a letter from the Parliamentary agents to the South Metropolitan Electric Light Company, enclosing a copy of a letter from the Board of Trade stating that it was proposed to consider objections to the license at eleven o'clock on Friday, when the representatives of the Commission of Sewers were requested to attend. The chairman said on the last occasion a resolution was passed by the Commission instructing the Remembrancer to lodge objections to several Bills in Parliament, this being one. The Remembrancer did lodge objections accordingly. The area laid down by the company included part of the area called the Blackfriars site, with regard to which the Commissioners were at the time in negotiation with the Brush Company. This was one of the choicest sites in the whole metropolis for electric light, comprising all the newspaper offices. Since then the Commission had declined to go further with the Brush contract; therefore, an important factor in their application was removed. They had already four applications before the Commission or its committees from four electric lighting companies, with offers to light the whole or a portion of the City.—The Remembrancer (Mr. Goldney) said the previous evening one of the firm of Messrs. Bircham and Co., Parliamentary agents acting for the South Metropolitan Electric Light Company, called upon him to intimate generally that he thought the company might be disposed to discuss terms or meet the objections of the Commission. He (the Remembrancer) intimated to him that the Commission had powers under their own Acts to undertake the whole of the electric lighting themselves. He had since received a letter from the Parliamentary agents asking if it would be satisfactory to the Commission if a clause were inserted to the effect that the powers of the company in the Blackfriars district might be hereafter annulled at the request of the Commission.—The chairman was about to read the objections of the Commission, when the engineer (Colonel Haywood) suggested that they ought to be taken with closed doors.—This was agreed to, and the rest of the sitting was *in camera.*

SIR JOHN PENDER, K.C.M.G.

The honour of knighthood which has been recently conferred upon the subject of this memoir, and the banquet which was given to celebrate the occasion at the Hôtel Métropole last Monday evening afford a suitable opportunity for continuing the series of *Electrician* portraits which from time to time have been presented to readers of this journal. A small woodcut of Sir JOHN, then Mr. PENDER, has among others appeared in these pages some years ago; but the larger steel plates have been hitherto devoted to the portraiture of men associated exclusively with the scientific development of electric telegraphy. To the hardly less important services rendered by its commercial development the distinguished gathering last Monday evening bore ample testimony, and we have great pleasure in this week being able to publish an excellent portrait of Sir JOHN PENDER, to whom, more probably than to any other individual, that development has been due. Sir JOHN, as everybody knows, is the Chairman of the Eastern, Eastern Extension, Direct United States, and Globe Telegraph Companies, and is the ruling influence in the councils of several other submarine cable companies. But it is, perhaps, not so widely known that in the early days of oceanic telegraphy, when the great experiment in the Atlantic had been tried and had failed, and when the promises held out by electrical science had been almost abandoned in despair, it was Sir JOHN PENDER who pushed the enterprise to a successful issue with the help of his money, his commercial credit, and the whole weight of his personal energy. At a critical moment in the history of the first Atlantic cables the project might have been delayed indefinitely but for the confidence inspired by Mr. PENDER'S heroic offers of assistance. A quarter of a million of money was needed to complete a new cable and make a fresh trial; and for this amount he gave his personal guarantee. The fact seems to have been that Sir JOHN, as has ever since been his custom, took pains to satisfy himself as to the scientific and mechanical problems of the undertaking; and having consulted the highest authorities on these points attacked the financial difficulties himself with perfect confidence in the result. Sir JOHN is a warm patron of science, and to his enlightenment and liberality in this particular are largely due the improvements which continually are made in both the manufacture and the working of submarine cables.

A few particulars of Sir JOHN PENDER'S life and career may be of interest here. He is a native of Scotland, his birthplace being the Vale of Leven, Dumbartonshire. As he was born in 1816 he is now in his seventy-second year, although, as will be seen by the portrait, which is from a photograph taken only in the present year, he looks at least eight or ten years younger, and has still the vigour and faculties of a man not nearly his age. Coming to England soon after leaving the High School at Glasgow, where he finished his education, he entered the counting house of a factory in Manchester, and after a few years' time rose to the management of the establishment. His success in business on his own account later on proved remarkable, resulting in the acquisition of a considerable fortune in the export trade of that manufacturing city, previous to his coming to the Metropolis. His first connection with the telegraph appears to have been in the capacity of chairman to the British and Irish Magnetic Company; and from that period until now his chief energies have been devoted to the promotion of telegraphic enterprise. Sir JOHN represented Totnes in Parliament from 1862 to 1866, and subsequently sat for the Wick Burghs through three successive Parliaments. He is Deputy-Lieutenant of Lancashire and Middlesex, for which counties he is also a J.P., as well as for Denbighshire, Argyllshire and the City of Manchester. Sir JOHN PENDER has been twice married. To his second wife Emma, the daughter of Henry Denison, Esq., of Daybrook, Notts., the fine life-size portrait of Sir JOHN, by Prof. Herkomer, A.R.A., exhibited at the banquet on Monday evening, has been presented by her husband's numerous friends.

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

(Continued from page 537.)

In our last chapter the outline of the general progress of telephony in the United Kingdom, and of the various obstacles, legislative and otherwise, which had to be overcome, has been brought down to the present time. The important judgment which has just been delivered by the Supreme Court of the United States will, we trust, help by its weighty authority to smooth the future path of telephonic progress in this country, as well as in the United States. As the judgment is now appearing in full in the columns of *The Electrician*, it will not be necessary for us to consider it in detail; and we shall now proceed to the consideration of the formation and extension of the different companies by which the telephone system of the United Kingdom is at present being worked.

The parent of all these companies is the United Telephone Company, which, as we stated in a former chapter, was incorporated in June, 1880, by the fusion of the Bell and the Edison Companies, both of which had been formed some two years previously. In the first year of its existence its revenue amounted to little over £20,000, and its profits were under £400, but under the direction of its indefatigable chairman, Mr. James Brand, aided by the indomitable perseverance and keen business qualities of Mr. J. B. Morgan, as managing director, it already showed signs of the vigorous vitality which has enabled it to increase its gross revenue, within a period of little more than seven years, to over £100,000 and its profits to over £62,000.

During its first year it inaugurated the policy of ceding large districts to subsidiary companies, receiving in return sums in ordinary shares, and this policy it has continued to consistently follow, greatly to the advantage of the development of telephonic communication throughout the country. The rapidity of this development will be shown by the table on next page, which gives the dates of incorporation of the different companies, and statistics for the year ending in June, 1887. The letters O. and P. in the columns headed "Dividends" refer to Ordinary shares and Six per Cent. Preference shares respectively.

The United Telephone Company confines its own operations to the county of Middlesex and those portions of the adjacent counties included within a radius of twelve miles from the General Post Office, with a trunk line to Brighton. Its system of exchanges at present in connection with the Central Exchange at Oxford-court, Cannon-street, is shown in the diagram on next page, which indicates the number of exchanges by means of shaded circles, and their connections, without exhibiting their relative positions, which can easily be ascertained by reference to a map of the metropolis and suburbs. The dotted lines in the diagram show the connections with the central exchange, the continuous lines the connections between the local exchanges. The small figures show the number of wires connecting each pair of exchanges.

The United Telephone Company is at present making arrangements to considerably extend its system by establishing exchanges in those suburbs not yet included in the exchange system.

We may therefore anticipate a considerably increased rate of growth in the extension of telephony within the metropolis. Its rate of increase during the last seven years is shown by the figures given below, which give the number of exchanges and private wires in use in the metropolitan system on the 30th of April in each year:—

Year.	Number of Subscribers to the Exchange.	Number of Renters of Private Wires.
1881	914	186
1882	1,673	366
1883	2,745	576
1884	3,350	715
1885	3,820	835
1886	4,393	936
1887	4,619	994

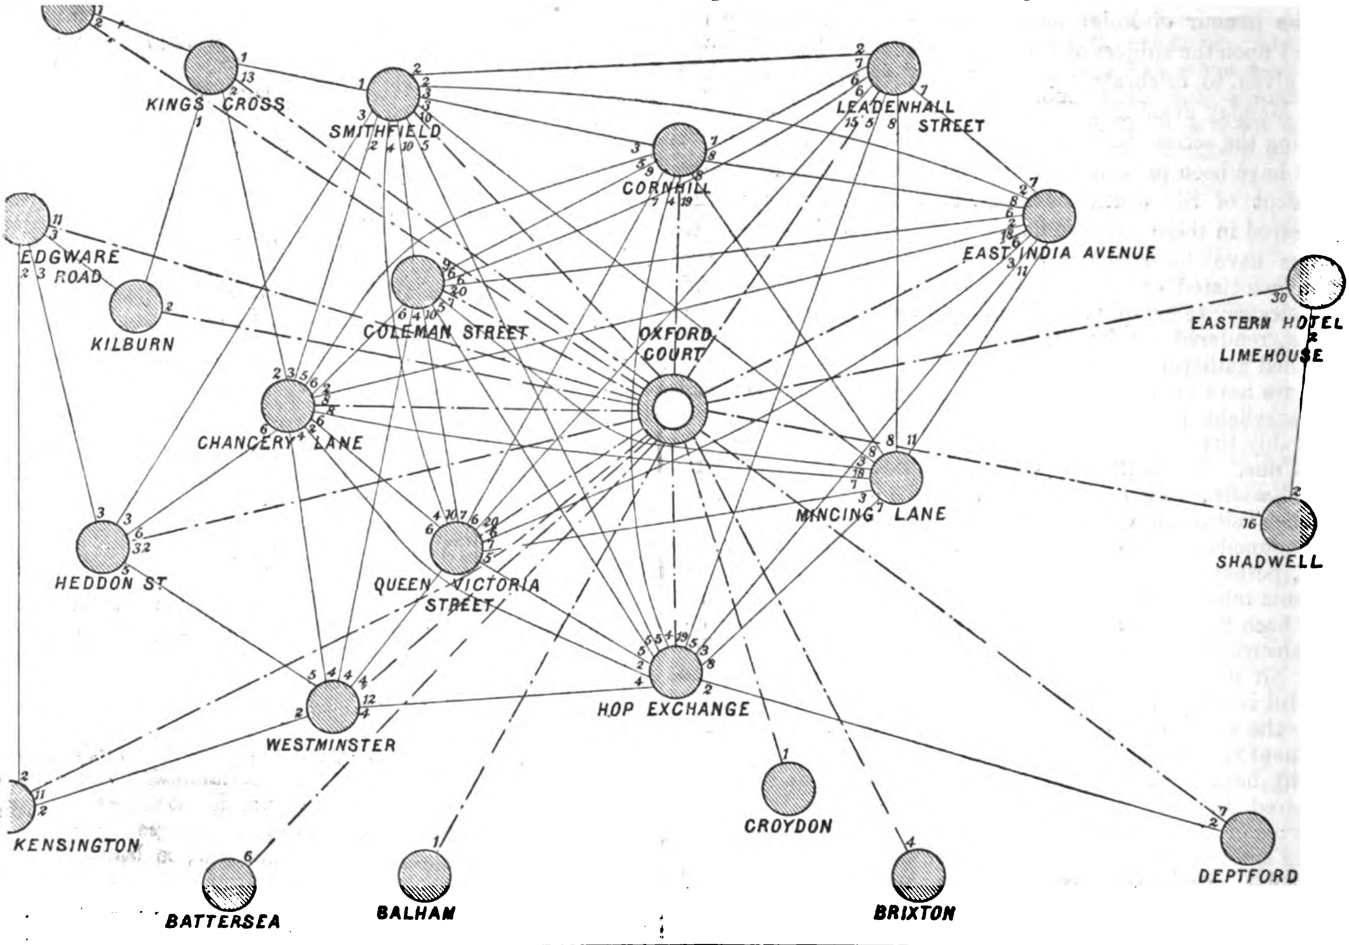
PLAN SHOWING NUMBERS OF WIRES CONNECTING TELEPHONE EXCHANGES IN LONDON WITH EACH OTHER AND WITH THE CENTRAL EXCHANGE. The Local Exchanges are not shown in their true positions.



The following table shows the financial growth of the company during the same period :—

Year.	Metropolitan District, Gross Revenue.	Rentals accrued and Sundry Receipts.	Expenses.	Net Revenue.	Dividend Amount.	Dividend rate per annum.	Reserve Account.	Carried forward.
	£	£	£	£	£		£	£
1881	23,017	20,645	20,274	371	*Nil.*	*Nil.*	4,045	371
1882	37,520	42,625	21,050	21,945	19,583	5%	6,345	2,362
1883	60,105	64,826	38,374	28,814	24,000	6%	12.364	4,814
1884	72,944	92,345	47,688	49,471	34,409	8%	60,275	5,061
1885	84,385	103,000	46,408	61,653	43,804	10%	76,863	5,291
1886	95,655	122,284	54,681	70,277	57,992	13%	97,233	2,285
1887	100,899	130,704	66,955	62,236	58,182	13%	102,646	4,054

Bonus of 10s. per share was declared for the year ended 30th April, 1881.

The total number of telephone "calls" in London during the twelve months ended on the 30th April, 1881, were rather over a million; while during the year ended on the 30th April 1887, they exceeded six and a-half millions. The "calls" for *one day* at the end of April were as follows :—

Year	1882	1883	1884	1885	1886	1887
No. of calls	12,224	19,609	25,957	31,776	32,727	41,947

The total number of "calls" per week for the different companies, for the year 1887, reached the following averages :—

United Telephone Company	221,764
National Telephone Company	420,000
Lancashire and Cheshire Telephone Company	211,500
Western Counties and South Wales Telephone Company	28,000
Telephone Company of Ireland	23,750
South of England Telephone Company	21,881
Northern District Telephone Company	12,690
Total	939,585

STATISTICS OF TELEPHONE COMPANIES, JUNE, 1887.

Name of Company.	Date of Incorporation.	Paid-up Capital.	Gross Receipts.	Net Receipts.	Dividends.	No. of Exchanges.	No. of Exchange Subscribers.	Calls or Messages per day.	No. of Private Wires.	Mileage of Wires run.	No. of Instruments in use.

The number of messages would be double this, or 1,879,170 per week, which gives ninety-seven and three-quarter millions for the year, and as the gross receipts for the same period amounted to about £320,000, the average cost per message to subscribers would be only a little more than three farthings.

There is but little doubt that this development of telephony has to some extent diminished the number of messages sent by telegraph, as might be expected. In illustration of this we give below a table given in the Postmaster-General's report for 1887 of the development of the Post Office Telegraphs since 1870, from which it will be seen that since the telephone has come into general use in 1880 the number of telegraphic messages did not increase so rapidly as it did previously until the date of the introductn of sixpenny telegrams in October, 1885 .—

Year.	Miles of Wire	Public Messages.	Receipts.	Expenditure.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

Chapter IX.—*Magnetic Fields.*

102. *Preliminary.*—One of the first considerations towards the understanding of the action of galvanometers is a clear conception of the delineation of the magnetic field set up in and around a coil of wire through which a current is flowing. The needle of a galvanometer is retained in the magnetic meridian, when there is no current through the coil, by the horizontal component of the magnetic field of the earth, and when it is deflected away from its position of rest we must take into account both the magnetic field due to the current which causes that deflection and the field of the earth tending to keep it in the meridian.

The relation between the magnetic field produced at the centre of a coil, the number of turns of wire composing the coil, the strength of current, and the angle of deflection of a magnetic needle free to move in the centre of the coil, is intimately connected with the principle of galvanometers, and it will be shown that the strength of a current may be measured in absolute units by means of a tangent galvanometer when the number of turns of wire, the mean radius of the coil, the horizontal magnetic field of the earth, and the deflection produced by the current are known.

To understand fully these points there should first be a clear conception of the fundamental units employed in the measurement of the intensity of a magnetic field, current, and strength of magnetic pole. To explain these and the manner in which they are co-related we shall have occasion to refer to the centimetre-gramme-second system, from which the units are derived. But we shall first examine the simple physical phenomena of magnetic fields as exhibited by—

1. Permanent magnets.
2. Electro-magnets.
3. Coils or solenoids.

103. *Magnetic Field of Permanent Magnet.*—There is nothing visible nor are there conditions in any way capable of affecting our senses in the immediate neighbourhood of a magnetised steel bar, yet we are well aware that pieces of iron or steel, whether previously magnetised or not, are powerfully acted upon by some invisible force when they are brought into the space surrounding a bar magnet. The whole of this space, which is capable of exercising magnetic force, is termed a "magnetic field" of force.

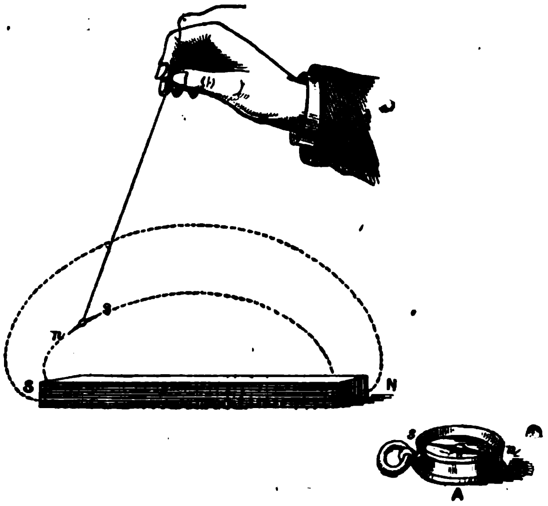

Fig. 60.

If a small compass needle, *n s* (Fig. 60), be attached at its centre to a thread of silk, so that it is balanced in a horizontal position when freely suspended by the silk, it may be employed to explore the character of the field of force round a bar magnet, N S, as shown. A good deal may be learnt by doing this simple experiment. The *direction* of the force will be the direction in which the needle sets itself. Of course, there is the movement here of "translation" or bodily movement of the needle, as well as its turning about its own centre, but by moving the hand about, so altering the distance of the needle from the bar and its position with regard to the ends of the bar, it will be found that when the needle is at rest in any position it will always seem to lie in the direction of curves existing between the two ends of the bar, as shown by the dotted lines (Fig. 60). It will also appear that the compass needle is much more powerfully attracted in some parts of the "field" than in others. This can be told by the rapidity of the oscillations it makes before coming to rest.

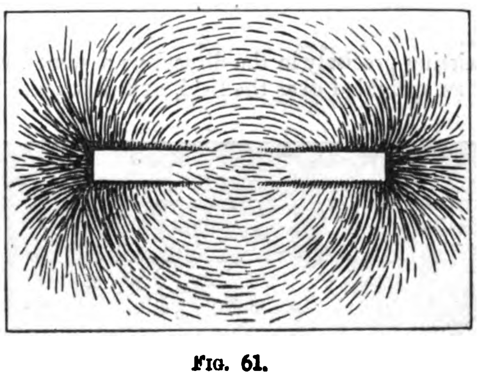

Fig. 61.

Close to the ends of the bar or at the "poles" the strongest force will be observed. In this country we term the north pole of a magnetic needle that pole which turns towards the geographical north, and a mark or cut is made on the north end of most magnets to distinguish this pole. The poles of the bar magnet and compass needle being known, it will be noticed that the latter invariably set themselves in such a direction that poles next to each other are opposite in name. By covering the bar with a sheet of stiff cardboard, or a plate of glass, and letting finely divided iron filings fall over it, at the same time gently tapping the plate, the general character of the

Digitized by Google

"field" is observed. Fig. 61 is a drawing from an actual field so taken, and exhibits the direction of the curves of force in the surrounding space. This, of course, only shows the field in one plane, but we should have the same character of field whichever side of the bar was uppermost; and hence the whole of the space immediately surrounding the bar is occupied by these curves of force.

Similarly Figs. 62 and 63 are drawings of magnetic fields taken on a powerful compound horse-shoe steel magnet.

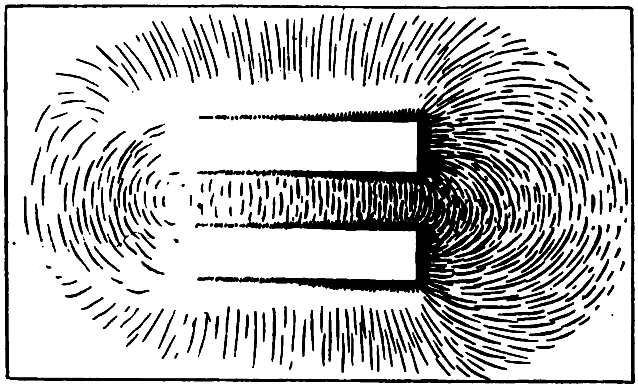

Fig. 62.

104. *Lines of Force.*—Faraday conceived that the space in the immediate vicinity of magnets was occupied by "lines of

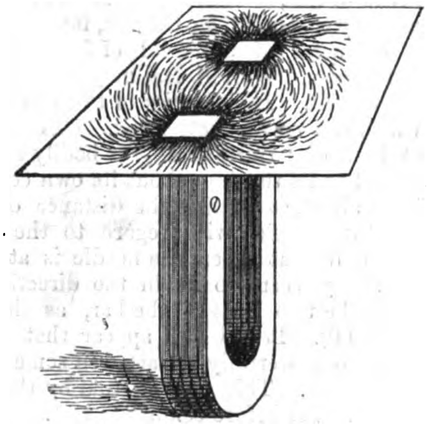

Fig. 63.

force, existing precisely in the directions assumed by the iron filings when sprinkled over the field, and this idea lends itself

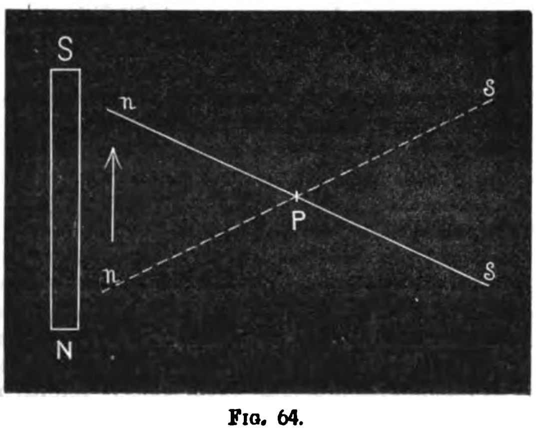

Fig. 64.

very conveniently to the explanation of the various observed effects. It is also convenient to assume a direction for the lines of force; for suppose that the bar magnet in Fig. 60 was turned round, putting the north pole to the left and the south to the right, the effect on the two needles would be to turn them to the right-about-face on their axes, showing that although the lines of force are still there, something has happened analogous to changing their direction. As a basis of reasoning it is assumed that the direction of the lines of force is that in which a free north pole would be moved along the field. As a north pole cannot exist in a "free" state without its corresponding south pole, the nearest practical way of showing this is by taking a long magnetised steel wire, *n s* (Fig. 64), pivoted at P, and holding it near to the bar magnet N S in the dotted line. The action of the distant south pole of the steel wire we may neglect, as it is comparatively so far away, and we have the north pole *n* separately subjected to the action of the bar magnet; and if the long magnet is allowed free movement its north pole will move in the direction of the arrow from N to S, being repelled by one pole and attracted by the other. The assumed direction of the lines of force is therefore from the north pole of a magnet towards its south pole through the surrounding space, but from the south to the north through the interior of the magnet, because all lines are supposed to form a closed circuit, which is completed through the mass of the iron of the magnet. It is also assumed that the greater the intensity of a magnetic field the greater the number of lines of force pass through a given area. We have now to show on what basis the unit magnetic-field is fixed, and as this depends on the force exerted on a magnetic pole placed in that field, the fundamental unit of force on the centimetre-gramme-second system must first be referred to.

JUVENILE LECTURES.

THE APPLICATION OF ELECTRICITY TO LIGHTING AND WORKING.*

BY W. H. PREECE, F.R.S.

Lecture I.

I appear before you to give a short course of two lectures on the application of electricity to lighting and working. To-night I shall confine my attention entirely to lighting, and if we succeed in getting through our subject, we shall devote ourselves next Wednesday to the application of electricity for working tramways, to the transmission of power for various purposes, and generally to working.

Many people imagine the electric light to be a cold light. That is a delusion. It is called a cold light because in many of its forms it gives what we may call a cheerless light; it has not got the warmth, the comfortable look, of other artificial means of illumination.

The electric light owes its existence to the intense heat that the electric current produces, and heat lies at the root of every system of artificial illumination. For instance, suppose we take a common match and light it, we light it simply because by the friction of the two surfaces together we generate heat; the heat burns the substance of which the match is made. We are able to light a common candle because we have applied heat to the wick, the heat liquefies the wax of which the candle is made, the wax is decomposed, it combines with the oxygen of the air, intense heat is produced at that point, carbon is consumed, and the consequence is light. So with all our various modes of artificial illumination. Gas, as you are well aware, produces intense heat, and the result of that heat is light. There are various ways in which gas is applied to produce heat and the necessary consequence—light. Here is a Sellon gas-burner, in which the combustion of gas raises the temperature of a fine platinum cap, and the result is, as you see, a very beautiful light. In one lamp we have a cap or mantle, in the other case there is merely a flat disc gauze of platinum. The combustion of the gas produces intense heat, which raises the network to a very high temperature, though in the present

* A course of three Lectures delivered before the Society of Arts on January 4th, 11th, and 18th.

Digitized by Google

case the light is not so good as it should be, probably through the pressure in the supply main not being sufficiently great.

In another case we have a gas jet surrounded with a network of some vegetable matter, linen or cambric, steeped in a solution of salts of zirconium, and a few other rare earths, and the intense heat of the gas causes a very high temperature, and, as you see, a very brilliant effect is produced.

You will see from this that in all cases of artificial illumination bodies have to be raised to a high state of temperature. I hold in my hand a piece of magnesium wire; it is really flat magnesium tape, but it is called wire. If I heat that you will observe that a very brilliant light is produced, due to the very high temperature at which it burns. Now, if I take a lump of coal and heat it—it requires to be raised to a certain temperature before the oxygen is directed upon it—and subject it to a jet of oxygen, you will see that it burns with very much more intense light than you are accustomed to in the ordinary fire. If I take a piece of iron wire and place it in a jar of oxygen, you see what a very brilliant effect the combination of oxygen and iron produces through the iron being raised to a very high temperature.

I have now shown you that in order to produce light we must, by some means or other, raise the temperature of a body. But the high temperature that we have to deal with is not that produced by the combination of the oxygen of the air and carbon, and other bodies such as I have shown you, but it is produced by the aid of the electric current. In all these cases the result of the combustion you have seen has been to remove oxygen from the air, but now I want to show you how a body can be raised to a high state of temperature without combustion of any kind. In front of me I have a fine platinum wire. In my hand I hold a wire that is in connection with a battery upstairs; the other wire in connection with the battery is attached to the far end of the fine platinum wire (Figs. 1 and 2). Now, when I make contact with the near end of the platinum wire, you observe that the wire is raised to redness, its temperature is high, and as I reduce the length of the platinum wire it gets brighter and brighter, the amount of electricity passing through it is greater and greater, and presently the wire is fused. I should have pointed out that as the quantity of heat generated in a wire increases, so does the colour of the light. When heat is applied to a body, that body is first warmed, then it gets gradually hotter and hotter, until it becomes red hot, and the first colour that appears is always red. The temperature is further raised, and the body assumes the colour of orange, then at a little higher temperature it appears yellow, and so the different colours of the rainbow are perceived according to the different temperatures to which the body tested with is raised. And now I want to show you the most intense form in which heat can be produced on this earth. There is no hotter object that we can obtain than that of the electric arc. I will try and produce this arc. You observe that when I bring these two pieces of carbon together a current of electricity passes between them, and the passage of the current of electricity between them creates such an intense temperature that a brilliant white light, as you see, is produced. Incandescent particles of carbon pass between the two points, forming a sort of bridge or arch, which is called the electric arc (Fig. 3). But the temperature of this arc is, as I said before, the highest temperature that we can produce; it has been measured, and is found to be 8,500° F. That is a temperature that can hardly be conceived; the melting point of iron is only about 1,200° F., the melting point of platinum, which is one of the most refractory metals we have, is about 3,000 F., but here in the arc we have the intense temperature that nothing can withstand, equal to 8,500 F. The colour is really due to the combustion that takes place between the materials forming the arc. I have just used two pieces of carbon, but I will now try other materials—copper, iron, and zinc. You will see a difference in the colour of the light, due to the fact that metal is burned in the arc instead of carbon. Every metal has its own distinct and particular colour, and the presence of the different metals can be detected by the character of the small arcs produced.

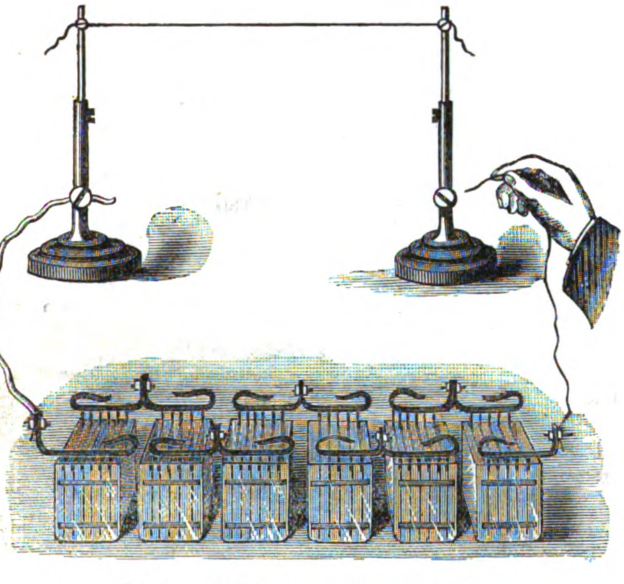

Fig. 1.—Fusion of Fine Platinum Wire.

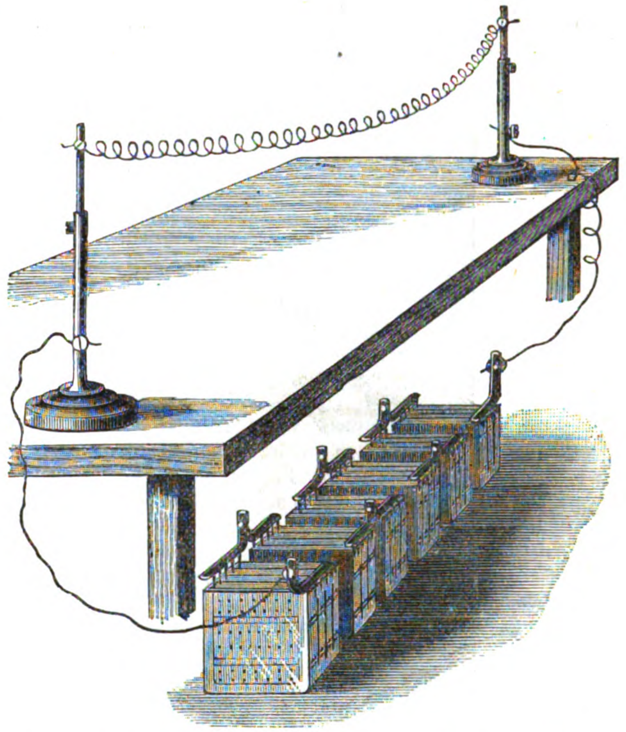

Fig. 2.—Heating and Expansion of Long Platinum Spiral.

I have shown you that we have two modes of producing intense heat, and therefore light, by electricity. I want now to show you how we produce electricity. The first essential for the production of electricity with a hand machine like this (Fig. 4) is a good dinner. The energy provided by beef or mutton enables the operator to turn the big wheel of the machine, whence motion is transmitted to the apparatus for producing the electricity. This machine when rotated causes a coil of copper wire to be whirled in a magnetic field, and that rotation of the coil in a magnetic field converts the energy derived from the grass and from the mutton through the machine into electric currents; those electric currents flow through wires that are under the table, they will appear in the two wires I hold in my hand, and will, I hope, reappear in the little glow-lamps I have before me in the shape of heat and then of light when I attach the wires. The light of the glow-lamp is of just the same form of energy as that which passed from the sun to the earth, and, by beginning backwards from the lamps we have

Digitized by Google

light, heat, electric currents, mechanical motion, food or fuel in the shape of mutton, grass on the South Downs, to the sun. Whichever way it is taken you will find that there is direct action between the sun and the glow-lamp. The lamps are now burning, and you see that we are able to produce electricity to our hearts' content. Downstairs there is a gas engine; the gas engine is at work; the gas engine works because the gas supplies energy which, stored up in the bowels of the earth in the form of coal for ages and ages, has been extracted; it has been converted into gas at the large gasworks down the River Thames, it has been brought up here, it is burned in the gas engine, and produces energy in the gas engine exactly in the same way as the mutton or beef produced energy just now. There is a dynamo down-stairs exactly like the dynamo that we have upon the platform, and the current that is produced is exactly as the current we just obtained, and is sending electricity through all the lamps in this room. The currents of electricity passing through the lamps are producing intense heat, the heat is producing the incandescence of a fine carbon filament, such as I will show you directly, and the consequence is that we are now being lighted in this room by the energy that unmistakeably and undisputably arrived on this earth millions of years ago in the form of sunshine.

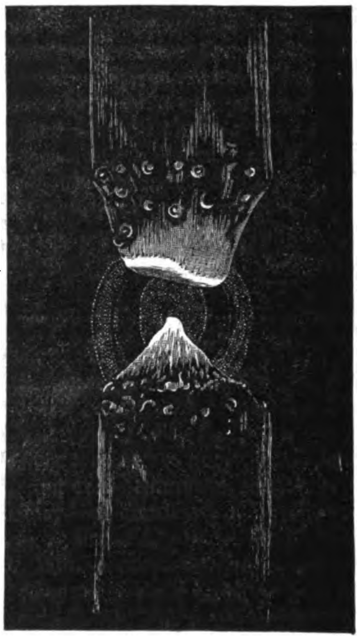

Fig. 3.—The Electric Arc (produced by Direct Current).

We can store up the energy in batteries. I shall show you to-night two or three different forms of battery. Here is what is called a primary battery. The only difference between a primary battery and a secondary battery is this: that a primary battery consists of chemical elements that at once combine and produce electricity by combustion, whereas a secondary battery involves some anterior electrical action, which prepares the surfaces of two bodies to put them in exactly the same condition as a primary battery. Here is a prmary battery known as the Schanschieff, which is charged with a solution of sulphate of mercury, and into that sulphate of mercury we will dip plates of zinc and plates of carbon. Zinc has a greater affinity for the sulphuric acid of the sulphate of mercury than mercury has; the sulphuric acid will at once combine with the zinc, it will burn the zinc just as the gas burned just now, but instead of burning with heat and light in the battery it burns in the form of electricity, which appears in the glow lamps attached. You see that the moment the zinc and carbons are placed in the cell electricity is produced, and the lamp is lighted. The form of battery from which we are drawing our electricity to-night is the accumulator, or the storage or secondary battery. The secondary battery simply consists of plates or "grids," as they are called, one filled with litharge, and the other with red lead; the one becomes pure lead, the other becomes peroxide of lead; the plates are combined in this form, and then placed in a glass cell; and upstairs there are 52 of these E.P.S. cells, which have been charged all day long by the gas engine of which I spoke, and which now contain a store of electricity that I shall make considerable use of to-night before I finish.

I showed you the form of electric light which we call the arc, and I have here to-night two or three different forms of arc lamps, which I will show in action (Fig. 5). But I want you to see this arc light for yourselves, and I want you to feel, as I feel, that in all nature there is nothing more wonderful and nothing more beautiful than the action of electric currents in the arc. The light is, as I attempted to show you, the very same light that came from the sun. I can show you that it is of the same character

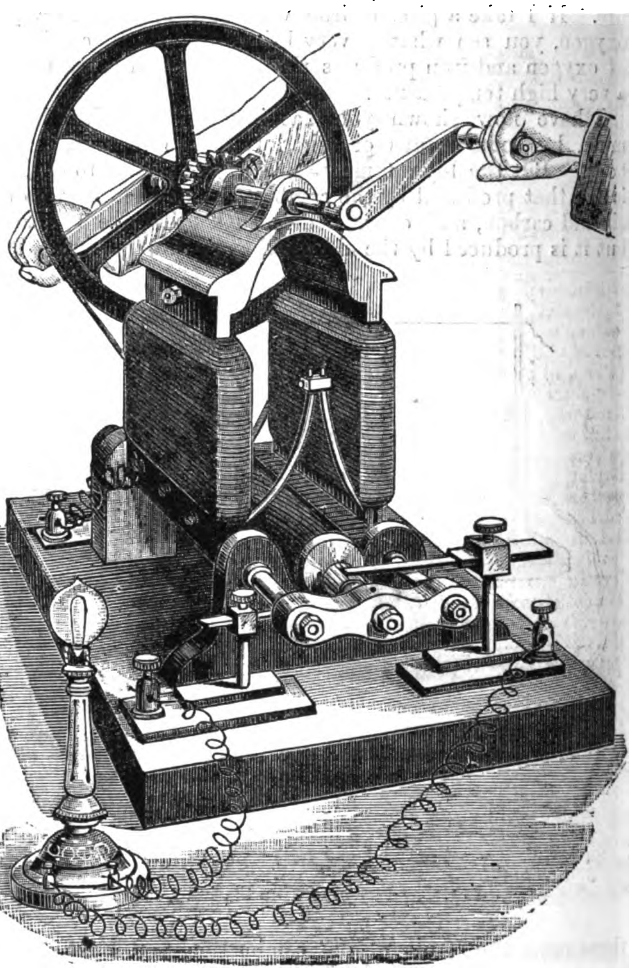

Fig. 4.—Producing Electric Light by the Hand Dynamo.

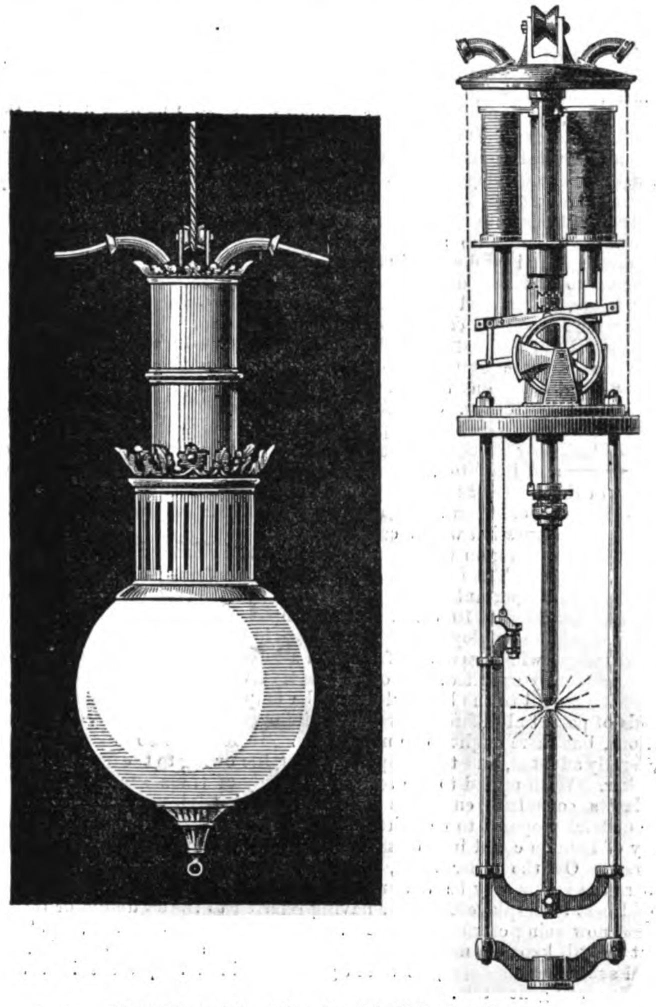
as the light of the sun, and in the lantern on the table there is an arc lamp the light of which we will throw on the paper before me in the form of a spectrum. There you see the spectrum in all its purity; the spectrum from the sun is no purer as regards light than what you now see. There you see all the colours of the rainbow, and I had intended, if it were possible, to show you in the first experiment, in which we raised platinum wire to incandescence, that the first colour would be the red, then the orange, then the yellow, then the green, then the blue, then the indigo, and lastly the violet. Beyond the violet there are rays of light which we cannot see; they are the rays that produce the photographic pictures, and, had time permitted it, we would probably have taken to-night a picture by means of the arc lamps, but it requires a long time to do so, and it really is no more interesting than an ordinary photographic picture. There are all the different colours of the rainbow. Those who are anxious to remember the order of the colours can very easily do so if they will remember this simple sentence, "Read over your good book in

Digitized by Google

verse." The first letter of each word in that sentence gives the first letter of the colour in the order of the spectrum. It would be a very good thing if some of our artists were to study and remember the colours of the rainbow, for it is an extremely rare thing indeed to find a picture with the colours of the rainbow properly depicted; sometimes they are upside down, sometimes they are mixed; and if you discuss the fact with an artist,



FIGS. 5 and 6.—The Brockie-Pell Arc Lamp.

he will say, "I do not care about your science. I simply paint my own impressions."

(To be continued.)

REVIEWS.

Papers Literary, Scientific, &c., by the late Fleeming Jenkin, F.R.S., LL.D. Edited by SIDNEY COLVIN, M.A., and J. A. EWING, F.R.S., with a memoir by ROBERT LOUIS STEVENSON. Two Vols. (London: Longmans, Green and Co., 1887.)

It is impossible to glance over these volumes without some feeling of astonishment at the wide and varied range of subjects on which Jenkin's intellectual activity was expended. Greek Art and the Modern Stage, Political Economy and Technical Education, Submarine Telegraphy and Mechanical Engineering, Evolution and Sanitary Reform, may serve as samples of the contents. It is, of course, inevitable that in the discussion of so wide a range of subjects the Papers should prove of somewhat unequal value; yet it may safely be said that in them all the author displays keen insight and a remarkable degree of intellectual vigour. There is frequently also a peculiar suggestiveness which enforces the conviction that the essays are not merely the chance fruit of idle hours, but are due to the fact that the author had arrived at ideas to which he felt compelled to give utterance.

It is needless to say that Jenkin's scientific fame rests chiefly upon his contributions to the labours of that school to whom, a quarter of a century ago, under the leadership of Sir William Thomson, we owe the development of those principles and methods by which electrical phenomena were brought within the range of exact measurement. It was Fleeming Jenkin himself who first systematically employed in practical work that magnificent system of "absolute units" whose importance was first indicated in Germany by Gauss and Weber. His determination in absolute measurements of the specific resistance of gutta-percha for the Red Sea cable of 1859, is the earliest measurement of the kind on record. In a note by Sir William Thomson in the volume before us, Jenkin is also credited with having been the first to determine by experiment the value of the micro-farad, and it will further be remembered that he took an important part in the work of the British Association Committee on electrical standards.

It is therefore a good deal disappointing to find that in the present volumes only two of Jenkin's electrical papers are reproduced. We should like to have seen a reprint of the "Cantor Lectures" on Submarine Telegraphy, delivered in 1866, and one would think that at least a few of his British Association Papers might have been included. Prof. Ewing is no doubt able to give good reasons for their omission, but he can scarcely plead that they are of too technical a character after admitting such a Paper as that on "Graphical Methods," which is inadequately described as "somewhat abstruse." However, it would be ungracious not to express satisfaction at the inclusion of the essay on "Submarine Telegraphy," which first appeared in the *North British Review* in 1866. In this Paper, the graphic story of the early Atlantic Cables is told with much force and skill, and the scientific principles involved are set forth in a wonderfully clear and interesting form. A very considerable historical value attaches, moreover, to the article, as containing the record at first hand of one of the very greatest achievements in applied science, and one in which the writer himself bore a distinguished part. It is, we think, much to be wished that the electricians—and particularly the "electrical engineers"—of the present day were better acquainted with the nature of the difficulties encountered, and the measure of the triumph achieved by the engineers (as well as the electricians) who solved the problem of the Atlantic cable. It would then, perhaps, be perceived that even if the marriage of electricity and engineering was celebrated with the Gramme ring, yet their august betrothal was arranged with due solemnity at an earlier period, and was due to the men who stretched a cable from shore to shore of the Atlantic Ocean. The engineering and mathematical skill demanded for this task was certainly not less than that required for the design, let us say, of an "alternate-current transformer." Take, for instance, the purely mathematical problem of determining the strains upon a cable during submersion, of which the true solution was first given by Sir William Thomson in 1857. It will be a sufficient indication of the complexity of the problem to mention that the Astronomer-Royal was more than once misled in his investigations on the subject. We say nothing at this moment upon the electrical side of the question, simply because the achievements upon which Sir William Thomson, Willoughby Smith, Varley, and Jenkin himself, amongst others, built up their reputation must be familiar even to the "third-year student." But we do wish to enter a mild protest against the prevalent impression amongst the younger school that electricity had nothing to do with engineering until they took the thing in hand themselves.

In this essay Jenkin goes into most interesting detail upon the expeditions of 1865 and the following year, and describes the various improvements, both in the manufacture of the cable, the methods of testing, and the equipment of the vessels, which distinguished the successful expedition of 1866 from that of the previous year.

But how much, after all, this success was really due, not to the perfection of the machinery employed but to the men who

Digitized by Google

handled it, the following extract may serve in some measure to show. Something had gone wrong in one of the cable tanks, several bights came up together, and in a moment it was seen that "five cables were running out from the tank instead " of one. These were carried aft together till they were stopped " by the paying-out machinery; when in a very short time " they appeared like the tangle of a gigantic fishing line. The " ship was immediately stopped; but the night was pitch " dark, rain falling heavily, and a fresh breeze blowing, the " cable over the ship's stem being only visible by a slight " phosphorescent light where it dipped into the water. Sir " James Anderson, however, by great skill, contrived so to " handle his ship of 23,000 tons, which was riding at single " anchor in 2,000 fathoms, by a mere thread, that the engi- " neers and sailors had time to reduce this apparent confusion " to order, and in about three hours the paying out was re- " sumed without the perfect testing of the cable having been " in the slightest degree interfered with."

The limits of our space will scarcely allow us to notice the valuable memoir by Robert Louis Stevenson at such length as its importance demands. The earlier half of Jenkin's life—from his boyhood till, in middle age, he settled down at Edinburgh—was full of picturesque incidents, and not even wanting in exciting adventure; and with all such passages as these it needs not to say that the biographer is in fullest sympathy, and brings to bear his choicest literary skill. In 1848 Jenkin was at school in Paris, and managed to see a good deal of the fighting in the streets. He then removed with his father and mother to Genoa, where the family arrived just in time to witness scenes of quite as stirring a character as those they had fled away from. In later days the love of activity and adventure which was thus stimulated in Jenkin was pretty fully gratified during his engagements on the various submarine cable expeditions—a task upon which, with some intermissions, he was occupied from 1858 to 1873. This part of the story is told chiefly by means of extracts from Jenkin's diaries and letters, although they are only of a fragmentary description.

After all, notwithstanding the grace of style and the sincere admiration displayed by the biographer, we could wish that at least the later chapters had been written by some one of his Edinburgh friends or colleagues who would have been more in sympathy with the scientific side of Jenkin's character. Mr. Stevenson does not hesitate to express his own distaste for applied science. On the whole we could also have spared some incidents of doubtful interpretation (in one of which Mr. Stevenson himself figures as an Edinburgh student), and the value of the work as affording a means of estimating Jenkin's true position in the roll of scientific fame would rather have gained than lost. We may bring to a close this necessarily meagre notice of a work which, in spite of the omissions we have deplored, is deeply interesting from beginning to end, by the following extract descriptive of what the biographer terms "his (Jenkin's) rarest quality":—"Fleeming would never suffer you to think that " you were living, if there were not somewhere in your life " some touch of heroism to do or to endure. . . . He loved " the harsh voice of duty like a call to battle. He loved courage, " enterprise, brave natures, a brave word, an ugly virtue—every- " thing that lifts us above the table where we eat or the bed " we sleep upon. . . . [Nevertheless] he loved the comedy " which shows a hero human, and yet leaves him a hero; and " the laughter which does not lessen love."

Telegraphs in Anam.—A line of telegraphs, about 1,000 miles in length, connecting Saigon with Hanoi, was opened for service on the 21st March. There are 26 intermediate stations.

Indian Telegraphs.—The *Indian Engineer* says that the telegraph line from Ghoom Station, four miles from Darjeeling, has been laid to within a short distance of Kalimpong, the wire being run from tree to tree through the forest. The line should reach Padoung by the 15th prox. The work is proceeding at the rate of eight miles a day.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

CENTRAL STATION LIGHTING.—TRANSFORMERS v. ACCUMULATORS.

(*Continuation of Discussion on Mr. Crompton's Paper from page 657.*)

THURSDAY, APRIL 19TH.

Mr. PREECE, in continuing his speech commenced at the previous meeting, recapitulated the three principal arguments in favour of batteries, namely, the convenience of storage, the utilisation of the current for motor purposes, and the fact that a small plant could be used during the whole of the day. He then pointed out that, on the other hand, there were also several arguments in favour of transformers, viz., that a higher E.M.F. can be employed, and therefore a smaller current in the distributing mains; that transformers are simple in construction, and can be easily stored away in odd corners, or, as Mr. Kapp suggested, below the pavement, and that no supervision is required; and that the efficiency of transformers is undoubtedly much higher than that of batteries. With reference to the load diagrams for electric lighting during the twenty-four hours, he pointed out that it was necessary in any case to provide energy for the period corresponding to the high points of the diagram, and that it did not matter much whether the capital was expended in the purchase of more batteries or in providing additional engine-power. Electric lighting on the transformer system had been successfully carried out by Messrs. Gaulard and Gibbs at the Grosvenor Gallery installation, which had been a pioneer for electric lighting in this country. The transformer system had also been used with favourable results at Eastbourne and Brighton, largely on the Continent, and to a still greater extent in the United States. With reference to Mr. Crompton's remarks as to the waste of steam in the secondary generator system, he considered this to be a question which concerned the engineering principle adopted rather than bearing on the question whether transformers or accumulators should be used. The loss took place in the engine room and not in transforming. An important question not raised by Mr. Crompton in his Paper was whether 30-watt 10 candle-power lamps or 60-watt 16 candle-power lamps should be employed. He himself was in favour of the smaller candle-power lamps, which gave satisfaction in all cases where the others had not been previously supplied. Another question which should be considered was with regard to the best voltage to be employed. In this country all kinds of potential differences were used indiscriminately in different installations, but there ought to be uniformity. In America 50 volts had been generally adopted, and the lamp had a long life owing to the filament being thicker. With regard to the relative economy of transformers and accumulators, consulting engineers had to base their advice on the nature of the district proposed to be lighted. A compact neighbourhood such as the City of London could best be served by the Hopkinson-Edison three-wire system. On the other hand, for a scattered district like Wimbledon, where the mains may be ten or twelve miles long, secondary generators could best be employed. After having referred to the accumulator installation now being carried out by Mr. J. H. Gordon at Whitehall, he stated that he still kept his mind open on the subject of secondary batteries, but until success was assured, he would give his opinion at present in favour of secondary generators.

Sir DAVID SALOMONS said he believed Tallyrand had remarked that every man ought to leave a son, plant a tree, and write a book. He had had the good fortune of having done all three, and it was the third, the book, which only interested them at that meeting. He merely mentioned this because he did not wish to advertise his views. He would like, to begin with, to criticise Mr. Crompton's figures. In the first place, he completely approved of Mr. Crompton's plan. Mr. Kapp on the last occasion took objection to the figures at which the accumulators could be produced. He himself had referred to a large number of notes from manufacturers and others on experiments he had made at home, and he felt sure that the figures were quite within the mark. He was very pleased to see that Mr. Parker, who spoke at the last meeting, also agreed with these figures, and that the price put—he thought it was £16 per kilowatt—was not at all an unreasonable one. He thought the efficiency placed at 60 per cent. was too low, and 70 per cent. might fairly be taken as a reasonable amount. Mr. Preece spoke of the paste falling at the rate of one pound a year—that is to say, after two years it weighed two pounds. He thought that was very high. He had been looking at some old cells since the last meeting, and he found that after eleven months there was not one ounce lost, and in the case of some old ones that he had got, there was not so much as a pound after three or four years, so that the probability of their lasting long was far greater than people imagined now that their constitution was being understood, and the old idea of undercharge was now completely reversed, and overcharging was the rule. One thing he wanted to call their attention to which Mr. Crompton seemed to have overlooked. He showed them a current curve, which was probably approximately correct, but he entirely overlooked that the day would come when motors would be used in every house, and that curve would be completely altered, and the output would be double or treble, because he foresaw that motors would take a great deal more current than lamps in the course of time, and that would alter the estimates very considerably. He would also refer to a point which had occurred bearing on Mr. Crompton's Paper: it was that of the absolute necessity, if they used the batteries as distributing stations, that they must be put two or more in parallel. In order to prevent absolutely a break down, he altered the installation at home from a very large series battery to two in parallel, so as to have

Digitized by Google

the advantage that if anything was wrong with one battery the other should be working. An accident occurred which might occur to anybody, and which proved the advantage of the two batteries. By some reason or other, in the morning, on entering the battery room, one of the glass cells (and it might happen of course to a cement box, or a lead box, or any kind of cell) had broken, and the acid had run away. That battery was completely cut out. If he had depended on a one-series battery it was perfectly evident that there would have been a break-down, notwithstanding the great talk about the certainty of accumulators *versus* all other methods (hear, hear). He mentioned that so that in future it might be discounted.

Mr. CROMPTON referred to some points touched upon by previous speakers. He said the regulation of groups of batteries placed in series was the simplest thing possible, and it had been carried out most successfully in Vienna. There had never been the least hitch since the commencement, and there was no loss whatever in regulation. The diagram on the wall (Fig. 3) represented three battery stations arranged in series. They might suppose a current entering the right-hand lower corner, and passing through the first battery, with the lamps parallel to it, passing away from the end of the first battery to the second, also through lamps in parallel, and so from the second to the third, and the third to the fourth. As to the means that he used for keeping the potential constant in those lamps, he had not yet pretended in these stations to use automatic regulation; but there was not the least difficulty in using automatic regulation. The main idea was to have a certain number of cells which could be connected either in series or else in parallel amongst themselves, and then in series with the rest of the battery. When it was required to increase the potential at the lamp terminals, one or more of these cells could be taken out of parallel and placed in series with the rest, and the lamp connection was at the same time shifted back to this point. That had been done by the apparatus on the table (Fig. 4). This switch had been at work for a year at Kensington Court, and it had worked perfectly satisfactorily. They placed the cable direct on to the fixed contact and passed the current through it into one of the ring contacts by means of the wheel, each ring contact being connected to a cell; or they could in large installations do it with a double ring such as those on the table—that was to say, he had one for the current entering the battery, and the other for going away to the lamps. The reason he had two was because under certain circumstances it might be advisable in fitting up a battery to be putting in current to a higher number of cells than they wished to take out from. That only occurred at certain intervals of time, and was not the usual condition of affairs. There was no loss whatever in connection with this method of using the battery, and such losses as took place were only at such times as the battery was discharging, or when the battery was too full, and that could only occur by the neglect of the attendant in charge. They would see that an apparatus of this kind lent itself to automatic regulation. But as hitherto they had had to keep a man in the battery station for other purposes—that was to look after the batteries at the large stations—that man might as well be employed as not. The changes that took place in the course of the evening were not very frequent ones, and the regulation was affected without difficuly. The apparatus had worked perfectly successfully at Vienna for nearly ten months without any hitch from beginning to end; and the same apparatus had worked at Kensington Court perfectly successfully. People were asking why he was not showing the Howell batteries. Everybody ought to know if they did not that Kensington Court had been worked entirely by Howell batteries for a year and three months, and he had never refused anybody who asked permission to see them; and anybody who wanted to see them, whether a

rival or a friend, was welcome to do so. It was therefore not quite fair to say they were invisible. The Howell batteries were there to be seen, and the largest installations that had ever been attempted were with Howell batteries (applause).

Mr. SWINBURNE thanked Mr. Crompton for his Paper, which was valuable because its data were based on practical engineering, and were not obtained simply by estimating in the office. On the question of alternating machines Mr. Crompton seemed rather sceptical about coupling in parallel. The question of employing alternating machines in parallel could not be discussed generally—it depended entirely on the alternating machines. Some forms could not be coupled in parallel, such as the Ferranti machines. Other machines would go in parallel perfectly, and would stand very large variations of load without getting out of step. The Westinghouse was about the medium, and the Westinghouse ran very well in parallel. There was a diagram on the wall in which he showed a method of saving the machines from getting out of step, if they had not been constructed quite properly. The rings marked A, A, A, A represented alternating-current machines. There were switches to each, and the top line and the bottom line were mains. The first machine was simply put right on the main, the second machine worked through a thing like a transformer, and the wires were so arranged that when it was perfectly in step with machine No. 1 the transformer was not magnetised at all, but immediately it began to get out of step the transformer stopped it. The third machine was put on in the same way, the transformer being specially designed by the proportions of the wire on each to work properly under these circumstances. By that means they could put any number of machines—even Ferranti machines—in parallel, and work with very large variations of load, and they might shut the steam off the engine without putting it out of step. The question of getting the machines in step to start with, of course, was a very simple one, and a great many little dodges for the purpose had been brought out, especially in America. It was such a very simple matter that it was not worth while going into it any further. Now, the problem of running alternate-current motors, once they had got them started, was very nearly the same as running the dynamos in step with varying loads, except that the variation of load was, so to speak, very much more important. He had shown therefore in the diagram a motor (M) which was supposed to be driven off the mains. It was provided with a regulator which was simply what Mr. Gordon called a

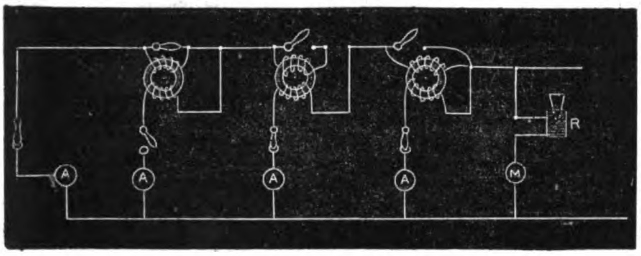

FIG. 5.

choking coil, except that the core was movable. Directly the load came on that motor it would begin to get out of step. Immediately that happened, the core of the choking coil was pulled down against the opposing spring, and that stopped the tendency at once, he thought. He believed in that way they could make a motor that could work fairly efficiently over large differences of load. As to the starting of motors, he did not believe any difficulty really existed. There were many ways of designing motors which were self-exciting and started themselves. One very simple way was to make the exciter itself with a laminated field. It was a doubtful sort of thing, but there was no reason why it should not be done. They might start the whole by passing some of the current through the exciter until they had got up speed, and then switch over suddenly. The reason why motors were not made just like direct-current dynamos with laminated fields was that their motors would have to be very large to meet a given output. That was the only objection to it. As to the transformers, a great deal had been said about testing their efficiency. He not think that it was really a point whether they lost 1 per cent. of their power in the transformer or 2 per cent. The point of importance was that they wanted their lamps to run at the same electromotive force, and they could not make the alternating-current transformer compound up, but they could make a dynamo compound up for varying lights. He believed, however, that there was no difficulty in making the alternating dynamos really to compound up without altering the field. It was a very curious thing; but it seemed quite possible. In fact, they were making a dynamo at Mr. Crompton's works which he hoped would do this. The mean volts fell off when the current increased, but the virtual volts rose, because the curve was steeper towards the end. As to the insulation, he did not think they had any very clear data as to the effect of alternating currents. He did not think it at all followed that they must have the same insulation with alternating currents. It was quite possible that the insulation that might break down under 2,000 volts in one direction would not break down under rapid reversals. Mr. Crompton's difficulty, he thought, would be his introducing 400 or 500 volts into the houses. He was afraid that would be a great drawback. As to the accumulators, he did not know quite what to say. He would rather like to quote Mr. Mordey's dictum—"That the great advantage of an alternating-current system is that people cannot go and put batteries on it" (laughter). It must be remembered that in discussing the question of alternating machines they had been making direct-current machines on scientific principles for some years, and they were only just beginning to do it with the alternating current. Even now alternating-current machines could be made to run at quite slow speeds, giving an efficient of about 98 per cent., and he believed commercially about 95. He thought they would be found later on very much cheaper machines than direct machines. That must be very carefully borne in mind. Returning to Mr. Crompton's scheme, he could not help thinking that the real solution of that problem lay not in taking 400 or 500 volts, but in the use of what one might term dynamotors, or motor generators. They would have the doubtful advantage of being able to use accumulators, but they would have several other advantages. They could do everything they wanted with alternate currents, except that they had to look after a pair of brushes; but if they wore working at local stations they had a man to look after the accumulators, and it was nothing for him to look after the brushes. These dynamotors had some properties that had not been realised. Dynamotors could be made to compound in the secondary circuit, even with a varying electromotive force in the primary. They could vary their electromotive force in the primary if they had changes in the load, without interfering with the secondary. This might not be so very important when they were working the sub-stations, but if they were working a large building direct it became very important. They might also charge batteries in their local stations on the primary circuit, and run the dynamotor on the discharge; he did not know whether that would be an economical thing to do.

General WEBBER said the one point to which he wished to draw their attention was the system by which Mr. Crompton proposed to lay down underground conductors. Mr. Crompton proposed to make subways with an interior cross section of about two superficial feet, and he proposed to suspend from the roof of that subway insulators to carry his bare conductor. He did not know whether the construction of this subway included any system of making it water-tight; but he could hardly conceive that that would be possible. Brick walls and concrete floor and flagging to cover would certainly not be, in any sense of the word, water-tight. Now, he could readily believe that for the first year or two years not much trouble as regarded the insulation of the conductor would arise. He had seen a good deal of underground work, having inspected a very large number of sewers and subways; and he felt sure before two years had elapsed Mr. Crompton's conductors and their insulators would be covered by detritus of various kinds. The brickwork and the sides of his subway would begin to wear away; the coverings of the floors would probably leak extensively; and in various ways Mr. Crompton's subways would arrive at such a state that the insulation would disappear. Again, they could readily imagine that those nice little roads under the footway would become a sort of "Rotten Row" for a large population of rats and their families—(laughter)—all adding to this condition which he believed would arise. It was understood that there was no means of obtaining access except at the connection boxes to any part of it without taking up the roadway. Under these circumstances he believed that it would be well if electrical engineers would look to the many years' experience of the telegraph companies, who spent large sums of money in laying down conductors which they had to take up from the beginning to the end. He had been engaged, amongst others, in doing a great deal of that work, and had arrived at the conclusion with regard to the maintenance of underground conductors, that it was only possible as a matter of maintenance when they could be withdrawn at pleasure. The drawing-in system was so well understood that he need not enlarge upon it in any way. Its advantages were perfectly evident to every engineer. As regarded a few of Mr. Crompton's calculations, he would like to make one or two remarks. That gentleman met them by a most clinching argument in favour of all his calculations, namely, that he would always do the work for the money. That was a very good and a very sound argument, and he thought that when Mr. Crompton estimated his means of distribution on the large scale, they must all feel that, from the point of view of the proportion it presented to the total, Mr. Crompton was not extravagant, particularly when they knew that the London Hydraulic Power Company found little difficulty in obtaining capital for the distribution of motive-power on a system which was infinitely more costly in every way. Mr. Crompton allowed 20 yards of main for every house, or 20,000 for a thousand houses. He thought that was susceptible of a slight correction. It was a very good thing to find an estimate laid before them with so large a margin, but anything that would reduce it would be an encouragement to investors, and in a district with which he was particularly well acquainted he had found that where the roads were wide—the frontages of the houses palatial to some extent—it was certainly well within 17 yards; of course that would reduce his 20,000 to 17,000. This brought him to the main feature of the economy which Mr. Crompton pointed out to them, and which he considered no doubt a very tempting bait in connection with the system of subways which he proposed. That was the saving which he made in insulation. It was not clear, without knowing the details of Mr. Crompton's calculations, what he included in those figures, but he would draw attention to the examples in which the cross-sectional area of the copper was half an inch. In one case Mr. Crompton made an insulation cost £35. 17s., whereas in the other example he gave (that was his own subway) it was only 4s. 6d. The latter was a very attractive figure, but it was not quite a safe one, he thought, because if 4s. 6d. was too small £35. 17s. was certainly too large. He gave the cost of copper in that instance as £54. 12s. for the whole, which divided by two made £27. 6s. for the 100 yards. It would be very evident to those who had gone into the figures that this figure should not exceed £22. That brought him to the question of the system compared with Mr. Crompton's, and as his own name had been connected with it, he might be allowed to say a few words upon that point. Person-

Digitized by Google

ally his interests in it were purely of a scientific character as an engineer, and his opportunities of trying it had been entirely due to his connection with the Anglo-American Brush Corporation, in whose yard, at the Borough-road, it was tried and upon exhibition for six months. The use of the bitumen concrete, he was glad to say, had been adopted to a certain extent by Mr. Crompton in his installation at Kensington Court, because he thought that every instance in which it got fair play and was properly used would bring to the front several of its conditions which were invaluable. Essentially it was a system of being able to withdraw the conductors when desirable without taking up the footway. Whether that would succeed or not the experience of those who had withdrawn cables which he believed were much more difficult to withdraw—namely, the telegraph wires—would go far to prove. The bitumen conduct could be bent with great facility on the spot, so as to meet all the varying conditions which might occur. If they took the City of London as an example, he might safely say that it was utterly impossible for Mr. Crompton's subway to be put down. Mr. Callender and Mr. Butler had been good enough to make for him the following tests, showing the breaking strains, crushing weights, specific gravity, and other data, connected with the bitumen concrete casing. The first test was made with a case 6 ft. in length, supported at two points 3 ft. apart, and weighted in the middle. The first indication of strain appeared with a load of 2,124 lbs.; and the breaking strain was in different cases 2,306 lbs., 2,130 lbs., and 2,457 lbs. respectively. A six-way case, 5½ in. by 8 in. square, with 2-in. ways, was also broken; the fracture was sharp and clear, and the channels were not disturbed. This was at a temperature of 50° F. Another six-way case was placed under a crushing weight of five tons without being affected. A 6-in. cube of the material was subjected to a crushing strain of eight tons without effect. These results, he felt sure, would be a very great encourangement to the future use of this arrangement (applause).

After a few remarks from Mr. SIDNEY WALKER,

Mr. HAMMOND said that he had very much pleasure in responding to the Chairman's invitation to tell them something about Eastbourne, especially upon the point which had been raised by Mr. Crompton in his Paper, and which had been commented upon by the other speakers. He considered that the question which had been raised by Mr. Crompton was the one crucial question which confronted all those who had to do with central station work. It not only confronted them at present, but it was one which some of them had had to deal with in the immediate past. Eastbourne had been mentioned, and he might say in connection with that installation that some two years ago they had to light the Town Hall. The problem was to put some three hundred lights into the Town Hall at Eastbourne on the condition that any number of the lights could be turned out at any time, with ten, twenty, or thirty left burning in the committee rooms or the whole three hundred burning at once. Under the conditions that they were then working, *i.e.*, the group system, it became impossible to carry it out on the plans then in vogue. They then had to consider whether it was best to place batteries into the Town Hall, and charge with a high tension current, or to put in converters or transformers. Two years ago, as the members of the Society knew well, the choice of transformers was very much limited; and having carefully considered the question, and having decided upon the transformers, their engineer, Mr. Lowrie, had to practically make his own transformer, but with this result, that the installation in the Town Hall at Eastbourne was, though he "said it who should not," the one thing that English electricians could look upon with great pride. All those who knew the installation at Eastbourne, and who had visited it, had seen that they had been able by means of transformers to solve the problem perfectly. On reading Mr. Crompton's Paper he was distressed to find that on the first page, when he looked about for facts and figures, the first fact with which Mr. Crompton enlightened them was that the installations at Eastbourne (where they had been working for some six or seven years) and at Brighton (where Mr. Arthur Wright's hard work as managing director in everything connected with the place was well known to many of them) were characterised not as honest attempts to carry out permanent lighting, but as "confessedly carried out in a temporary manner for the purpose of popularising the electric light and inspiring the confidence of the public in electrical supply as a form of investment" (laughter). This in a scientific paper surprised him, because, if during the last five or six years he had struggled for anything it had been to pay a dividend to those who had invested their money in the Eastbourne and Brighton Companies; and their last balance-sheet at Brighton, issued some six weeks ago, had passed through the crucial test of being passed by one of their largest shareholders, known to be one of the best accountants living. He could not help thinking this was a piece of unkindness, because Mr. Crompton also made use of words to this effect. He said, "It was hardly to be wondered at that what little knowledge exists on this subject should be confined to the few who have lighting stations under their immediate charge;" and yet in the next paragraph he said, "Do not take any notice of Eastbourne, they have only been carrying out a central station there for some six or seven years; do not take any notice of Brighton, which is begun upon a very small basis, and been getting gradually larger and larger;" and, in fact, Mr. Crompton said, "Do not take any notice of the Grosvenor Gallery, because they are only a set of advertisers" (laughter). That being so, he presumed that Mr. Crompton had himself taken no notice of them. Therefore, if he might trespass upon their time for about five minutes, he would tell them one or two facts connected with these two central stations which he did not think they would gather from Mr. Crompton in his reply. In the first place, they were working with transformers at Eastbourne, and on the direct system at both places. It was true they were working on a small scale, with some 1,500 or 2,500 to 3,000 lights, but he had learnt at Brighton that to start a central station one has to be contented with doing scattered lighting, and to gradually add fifty or a hundred lights at a time. At Brighton they had one of the hardest-working men and one of the most scientific men in England in charge, and yet, in spite of all that, they were only gradually obtaining little additions from time to time. Mr. Crompton said of the transformer system, that you had only to look at his load diagram to see the absurdity of it. Being about to put down a central station in London not very far from Mr. Crompton's Kensington Court station, he had had to weigh the question over again as to whether the transformer system or the battery system was the better, and he had again come to the conclusion that the transformer system was the better. Mr. Preece, in his speech, gave them a hint which he wished to enforce, and it was this. Mr. Crompton said in his Paper that of course in a transformer station you must have three complete shifts of men. He (Mr. Hammond) was at Brighton last night, where the current was supplied to customers the whole of the 24 hours; he was there at the busiest time, when the light was fully on, when every stitch was going, and he was there till late, when he saw one engine after another put down and down until there was only one engine running, and he was able to say that the labour that was being expended in Brighton was absolutely proportional to the load that was going on in the circuit. There were no full shifts of men. On leaving Brighton that morning, he called at the station, but did he find the same number of men working there as he saw last night? No, not at all; he only found two men working. To say that under the transformer system it is necessary to have three times your normal staff, is the talk of people who would know very much more of the subject if they went down to Brighton and Eastbourne and observed it actually in practice (applause). Therefore he said with regard to the question of economy in working a central station, Mr. Crompton must be as far wrong in the facts and figures relating to it as he was upon the motives that were inspiring and had inspired them for five or six years. Mr. Crompton was also as wrong as to the way a transformer station was to be carried out as he was upon the other thing of which he spoke. He came that night to listen to this scientific man and to get inspiration from him. It was just at the moment when the order had not been given out for the first London station of the House-to-House Company, and if Mr. Crompton could convince him and his directors that his system was the best plan he would be willing to adopt it. At Eastbourne they were working entirely with transformers, and at Brighton they were working with a direct system, the transformers being gradually put on to it. The next point was reliability. They were told by the last speaker that under a battery system they were perfectly comfortable. Now where did the reliability come in in a battery system? What was the reserve of force upon which they could rely for continuity of lighting? They had a chemical and electrical storage—that was their reserve. Speaking in that room, with many civil engineers around him, he asked which was the better to rely upon—whether it was that chemical reserve or a mechanical reserve which could be thrown on at any moment? He ventured again to appeal to experience, because Mr. Crompton had chosen to sweep away all outside experience. At Brighton one engine was always ready in reserve. If the burden of work was sufficient to occupy only one engine, then only one engine was doing the work; but there was a second engine ready with the steam up. Mr. Crompton spoke of a supposititious engine, which apparently was liable to suddenly burst right up into the air without giving the slightest intimation (laughter). His own experience of engines was this. They had heard from Mr. Swinburne of a nice little arrangement that rang a bell in order to tell you that something was wrong. And so with engines: if they did not absolutely get up and ring a bell (renewed laughter), there was always a little leakage by which the practical eye of the man who is in charge of the engine shows there is something going wrong. His engine always gave notice if there was something wrong in its inside; there were oceans of time if they wanted to throw on a second engine (laughter). They had never at Brighton been so taken by surprise that they had had a stoppage of a continuity of light, or any instance of not being able to rely upon their reserve force. He therefore held, as the only perfect method of having reliability and continuous running, that they must have their reserve in engine-power ready to put it on at any moment, and they must not put into the circuit these wretched accumulators. Undoubtedly, if there was one portion of their central lighting station at Brighton that they were afraid of, that was where the accumulators were in use, for they had a few in private houses, which enabled them to compare the two systems. In practice they found that instead of giving the efficiency that Mr. Compton claimed, they only got an actual efficiency of 60 per cent. Mr. Crompton, in making up the figures, said 80 per cent. was the output of a perfect accumulator. His company had found from experience that that was not so—that it was 60 per cent. Many gentlemen present would confirm those figures. What does Mr. Crompton say with regard to efficiency? He said that when the station work was going at pretty full swing they got about 70 per cent. efficiency in the converters. He could only suppose that Mr. Crompton had not yet seen an efficient converter. A battery which gave an 80 per cent. efficiency must be an extraordinary battery; but the converter which is content to give a 70 per cent. efficiency at full load must be an atrociously bad one. He could take Mr. Crompton down to Eastbourne, or anyone else who was interested, and show them converters working at 95 per cent. efficiency. There was only one point more, and that was this. Their experience at Eastbourne was dead against Mr. Crompton's figure of having to put aside 10 per cent. depreciation on converters. What is the wear and tear on a converter, say in comparison to that on a dynamo? They did not take off 10 per cent. depreciation on dynamos. They had at Brighton some of the Brush dynamos that were first put in there that had cost them only 33s. or 34s. a year for repairs; probably Mr. Wright would be able to give the exact figures. They did not put 10 per cent. depreciation aside even for that; but this silent, quiet thing that was doing no active work, that had no moving parts and no chemical arrangements to get out of order, why put aside 10 per cent. depreciation on it, and only put aside 15 per cent. depreciation on the accumulators? He said on these points the experience which Mr.

Digitized by Google

Crompton had brushed aside was dead against him on the four points of economy of load, reliability, efficiency and depreciation. A stranger would suppose, on reading the first paragraph in the Paper, that the Eastbourne system was an overhead system. Mr. Crompton spoke of "Eastbourne, Brighton, and, in fact, all overhead systems." Eastbourne was an underground system. The last speaker had said that the insulation would break down as soon as they attempted to pass 2,000 volts through the cables. At Eastbourne they had some seven miles of mains, they were underground; they did pass 2,000 volts through (that was their charging current), and they lived through it all (laughter). They relied on underground-working; they made careful tests of it, of course, but they found no difficulty about it, and he was astonished that, in the face of the absolute experience at hand in a place within arm's reach, it should be said that the great thing against the transformer system was that it necessitated such a high current as 2,000 volts. He must say that on examining closely into the four or five leading facts in the Paper which he was able to check by absolute experience of lighting stations—small though those places were, though growing daily—he did not place much confidence in Mr. Crompton's conclusions (loud applause).

Mr. A. P. TROTTER: Mr. Crompton has, I think, rather shaken the faith of a good many of those who rely on transformers as the system of the future; many of us feel that he has thrown quite a different light on the matter, and I for one should not like to say that batteries will not be part of that system. But there are several points which have already been raised which show that the time has perhaps hardly come for this. I do not know if the diagrams on the wall represent a station where motors are being used,* but as has already been pointed out, if motors are used, the daily consumption will certainly be as high, if not higher, than what we see on the diagrams. Perhaps one of the most serious objections to batteries is that of their efficiency and their life; but when the time comes for battery makers to give an absolute guarantee, and to undertake to repair and to keep in order, without stopping the current, the batteries which they supply, for a sum of say 10 to 12 per cent., we shall be in a very different position. People will hardly like to sink so much money as Mr. Crompton recommends upon batteries, judging from the experience that we have had during the last three years. As to the efficiency, we know that 60 per cent. is about the usual thing for a battery which is at one time charged and at another discharged. Mr. Crompton has given us a very different figure, viz., 80 per cent., and I hope in his reply he will explain if it is due to the short length of time during which he is really discharging from his battery that this very high efficiency is obtained. The question of reserve has already been discussed, and it seems much better to have separate engines and dynamos than a battery reserve, unless two sets are used, and then no doubt troubles arise and there is the double expense. If you have six dynamos of 100 kilowatts each, you always have one or two of them with the steam up, and either just ready to start or having lately stopped, and, except at the short time of full load, you will always have the opportunity of turning another one on within a few seconds, and even at the full load there should be at least one in reserve. It is most discreditable to this country that at the present time there are so few installations with a single dynamo and engine in reserve at the time of full load, and perhaps as much harm has been done to electric lighting on account of the absence of such a reserve as from any other reason. In the case of waterworks where they have perhaps two engines to do the ordinary work and three for the full load, there is always one in reserve, and in a central lighting station with six or eight 100 electric kilowatt dynamos, with one in reserve, there will be ample time for overhauling and repairs. I would like to ask Mr. Crompton why he has put down 60 volts for the lamps at the transformer station. It makes some little difference to the calculation; but what is more important in working out the comparison is, that he has assumed that two out of every three houses will, at no distant date, be wired and running. This is rather unfair to the alternate-current system, because if we have for some years to come only two out of ten houses, it makes an enormous difference in favour of the transformer system. Again, in speaking of the very high insulation required for the high volts, is it necessary, in the face of the most valuable tables that are given in this Paper, to go so far as 2,000 volts? A great deal has been said about the copper varying inversely as the square of the volts, and so on; but considering the percentage of copper in the tables before you, its value is a ridiculously small amount, and if you take 3,000 volts, as has been suggested by some, instead of 2,000 volts, you get about 22 millimetres instead of 50 millimetres for the area, and you only save 22 per cent. of the total cost. No doubt the proportion of copper in the two cases is as 4 is to 9, but still, according to the figures in the Table No. 1, the cost will be about £11,200, against £14,270, and if you reduce down to 1,500, which is the point suggested by Prof. Elihu Thomson as the limit of high volts, you get 90 millimetres, which would cost £90 per 100 yards, or an increase of 26 per cent., according to Mr. Crompton's figures. I quite agree with Major-General Webber, who has pointed out that the bare copper seems likely to get into difficulties, and I should say much more so than a properly laid cable in a good tube or culvert, and it certainly seems hardly fair to give a higher rate of depreciation for the bar copper than for the insulated cable. Mr. Kapp has spoken of large transformers which are "banked" on a common network, but he did not suggest what should be done when one breaks down and throws a heavier load on the others. No doubt he thought of that before suggesting the method. But supposing that these large transformers are put down at the present day, when only two out of ten houses are taken up, when the time comes for two out of three we can surely afford to get a room in a mews, as suggested by Mr. Crompton, and probably the room over it can be had when the time comes for exchanging them for batteries and an attendant. It is quite possible that the time may come when batteries will be used to the exclusion of transformers, and then the only change will be in the dynamos and the transformers, which are not a very serious part of the whole. The houses will be ready wired, and the mains might be arranged so as to be available for either system. A question has been raised about the difficulty of working with high volts with batteries, and I see no reason why Mr. Crompton should not go further with his high volts, and put down yet more batteries; for nothing could be easier than to run several dynamos in series, for we all know that this is not a difficult matter, certainly not half so difficult as to run alternate-current machines in parallel. There should be no reason why in the future, when we come to something like unanimity on the subject, several stations should not be thrown into a general system; or at all events one district could help another, as is done by the waterworks in the North of England.

The discussion was then adjourned until Thursday, the 26th inst.

* Dr. Fleming informs me that this is the case.—A. P. T.

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

THURSDAY, APRIL 19TH—*continued.*

In his re-examination by Mr. MOULTON, Dr. JOHN HOPKINSON said in Mr. Edison's patents, specifications, and designs, many other modes of making the filament had been proposed, but so far as he knew they all fell within Mr. Edison's claim, or within that which he described. A very large number of people had been using endeavours to get the very best possible filament. The fact that the filaments were made with some of these improvements did not, in his opinion, show that Mr. Edison's method was impracticable.

Take first the difficulty which is suggested of carbonising a small object like this. In your opinion would a person trying honestly to carry out the instructions of this specification take care to eliminate the small quantities of oxygen?—Oh, yes; the most elementary knowledge of chemistry would tell him that.

Do you think, with knowledge of the improvements, it is possible to make a practical lamp with wood splints?—I have not the least doubt about it.

Have you any doubt as to the infringed lamp containing a filament?—Oh, no; that is palpable and distinct.

In your opinion is there anything in the provisional specification of Lane-Fox of 1879 which would be sufficient to enable a competent workman to construct such a lamp as is described in Edison's specification?—Certainly not; it does not even tell you that you are to carbonise the material after it has been formed.

Is there anything to show that it is to be a filament it all?—No; I should rather infer it was to be of considerable section.

Down to the present time have you ever heard of any lamp being made according to the description here?—No.

With regard to the 1879 patent, are there sufficient instructions there to enable a competent workman to make such a lamp as is described in the Edison patent?—Certainly not.

Have you ever down to the present time known a lamp so made?—No; I do not think so.

Mr. JUSTICE KAY: You mean according to Lane-Fox's specification.

Witness: According to Lane-Fox's specification.

Witness also said, with reference to the Carré carbons, that they were made also exclusively for arc lighting. He did not know that they were ever made for incandescent lighting.

With regard to the Cheesborough patent, witness said that a competent workman desiring to carry out that invention would have no difficulty in doing so if he had before him the description of Cheesborough.

Mr. JOHN IMRAY, in reply to Mr. ASTON, said he had given particular attention to the construction and use of incandescent electric lamps since their first introduction, at all events during the last twenty or thirty years. Referred to the specification of Edison's patent, witness said he had made himself familiar with it. He agreed with the evidence of Sir Frederick Bramwell on the point, with the addition that he thought the filaments might be made in all the various ways described, and would work well in all those ways.

Did you give that as a mere matter of opinion, or did you try experiments which justify you in coming to that conclusion?—I have tried five of them.

Witness also said that he was acquainted with the contents of the Cheesborough specification; as regarded the directions for the preparation of the carbon, he thought they were very simple and very clear. On this point he also agreed with Sir Frederick Bramwell and Dr. Hopkinson.

Cross-examined by Sir HORACE DAVEY, Witness said he examined the lamps yesterday, and the reason why he did not submit them to a longer examination was because he had not the time for it. His experiments would give no information as to the durability of the filament.

I observe on the lamp with the cotton thread smeared with lampblack there is a brown sooty deposit on the glass after only trying it for two or three minutes?—It is scarcely sooty; I understand this was worked previously. I think that is most likely some of the vapour of the tar. The attachment to the platinum wires is by means of the compound of lampblack and tar.

I am told that is impossible, because that little cross-piece of glass would have been melted if it had been?—If it had been carbonised after the attachment that piece of glass would have been melted; it could not have been carbonised after the glass was there.

You do not call that a practical lamp, surely; did you ever see such a clumsy lamp as the one called J I 3? Do you call that a filament?—

Digitized by Google

Yes, I do. I did not try the resistance of it, but I should think it is a low-resistance lamp.

Another lamp, F J B 1, was then handed to witness, who said it differed from J I 3 in this respect, that what he called a filament was a thing that was flexible before it was carbonised, and he did not think F J B 1 (Swan lamp) was. Asked whether there was anything in Edison's patent showing that it was to be flexible before being carbonised, he said all the modes of making it described in the patent would produce such a filament. That was not the only distinction he could draw between these two lamps. In Swan's lamp, for instance, the rod or stick of tar was of considerable size; in the other lamp the width was relatively considerable, but the thickness was very little. He did not know whether the cardboard one which he produced was of higher resistance than Swan's lamp, and could not form any opinion, because the resistance depended not only upon the sectional area, but also upon the quantity of carbon.

Assuming that the conductor in Swan's lamp received its present form before it was carbonised, can you draw any distinction other than what you mentioned between those lamps?—No; except that I do not think in Swan's lamp this is of the nature of a filament, and flexible.

Do you know that Swan's lamp burnt for an hour?—I have heard so.

Mr. ASTON: 40 minutes?

Having regard to the fact that his claim relates only to the method of making the illuminating portion of the lamp, do you not think that Cheesborough contemplated that the material which he does obtain in the way described would be useful for that purpose?—I do not think so.

At the request of Sir Horace Davey it was then arranged that one gentleman from each side should measure the resistance of lamps J I 1 to J I 5, and the lamps were then handed over to the parties, who left the court for the purpose of examining the lamps.

In re-examination by Mr. ASTON, Witness said that the brownish deposit on the inside of the globe was not usual now that the filaments were very much improved, but it was very usual at first.

Mr. EDWARD GIMINGHAM, in reply to Mr. MOULTON, said he was in the employ of the plaintiff company. Edison's specification had been placed in his hands, and he was told to make certain lamps from it. That was two years ago, and again at the beginning of this year. Mr. Imray had produced certain lamps—J I 1 to J I 5—which had been all made by him (witness). Some of those lamps were made four years ago, before the trial of Woodhouse and Rawson; but, although in court, they were not then produced. Beyond the instructions given in the specification no instructions were given to him in making the lamps, except a special instruction not to pass the current through the filament while it was being exhausted. Witness then described in detail the manufacture of the lamps in question.

His examination had not concluded when the Court adjourned for luncheon.

In cross-examination by Sir HORACE DAVEY, Witness was asked as to the several descriptions of lamps which he had manufactured since entering the employment of the plaintiffs. He stated that he made them from the specification of Edison's patent, and with no other instructions. Questioned as to a lamp with a cotton thread burner, and asked how he carbonised it, he explained that he took some ordinary sewing thread off a reel, and made a little framework of wood with two carbon rods, round which he wound the cotton, in order to get the shape. He then put it in the crucible and dusted in some plumbago, and heated it very hot over one of Fletcher's gas furnaces.

I suppose you previously knew how to make filaments?—I knew how to carbonise, and reading in the specification that you were to carbonise I knew that you must exclude air.

Where are there any instructions in the specification about the exclusion of air?—There are none, but I knew air must be excluded in order to carbonise. It simply says make it into a spiral.

You made a wooden frame?—Yes; to keep the carbon rods apart. I put them into a conical shaped crucible and dusted in lampblack.

Where do you find any directions in Edison's specification as to wooden frames?—There are none; I chose the way which I thought best.

Where are there any directions about plumbago?—I do not see any. I thought that would be best. I closed it as much as possible by filling it up.

What was the object of winding the thread on anything?—To get the shape.

If you had not taken some precaution it would have been crinkled up, would it not?—Yes; I suppose so. Before I made the wooden frame I tried placing it amongst broken bits of plumbago, but the result was that it was distorted. I tried several ways; it took two or three days before I discovered the best way of doing it.

Did you try the putty filament?—Yes; I rolled the putty out into a long, thin filament.

You did not carbonise that at once?—I let the putty dry, and then fastened it on wires, and put it into an oven to drive off all the tar.

Do you suggest that that is in accordance with Edison's directions?—He says carbonise, and I took the best means I could. I expected the tar would go off.

Does not Edison tell you to carbonise the putty wire before it is attached to the platina wires, and then carbonise the whole thing?—It does not direct you there to join it to the platina.

Was it not very brittle?—It was brittle compared with the other. I do not think it would stand handling with the fingers.

What precaution did you take to preserve the shape?—I made a spiral of copper wire, and then placed the flexible lampblack and tar between the coils. I afterwards dissolved the copper, and the spiral was left.

Can you show me a lamp with a filament of that sort?—No.

What heat did you use?—A copper oven heated by a Bunsen underneath. I thought if I got the lampblack and tar into the bulb it would do without having a spiral. I made a roll of paper, and wound the flexible lampblack and tar round it, and afterwards took away the carbonised paper. I put that into a lamp. They would not stand much knocking about, and soon broke in carriage. I should not choose that way of making a lamp, but I am certain that in time I could make one of those to be a practical lamp. All the other lamps are here. They light up very well indeed. I have lamps here that gave an average of 87 hours. They are thread lamps.

When you were exhausting the air from the bulb, did you use any external heat?—Yes; there was a gas burner underneath helping to drive the air out.

Re-examined: I had not been employed either by the Edison Company or the Swan Company before I made these lamps two years ago. I had a previous knowledge of chemistry. I had been to the Science and Art classes, and passed an elementary examination in chemistry at South Kensington; and in making these lamps I did my best with the knowledge I then possessed. Except that knowledge, and Edison's specification, I had no other instruction.

Taking any one of these methods given in the specification, could you have made practical lamps with it?—Certainly.

Dr. JOHN AMBROSE FLEMING, examined by Mr. ASTON, Q.C., said he had devoted considerable attention to the manufacture of electric lamps. He had heard the evidence of Sir Frederick Bramwell, Dr. Hopkinson and Mr. Imray, and he substantially agreed with those witnesses.

You have had practical experience in the testing of lamps?—I have.

Have you tested any of the lamps made by the last witness?—I have tested some of them by measuring. I tested the lampblack and tar filament lamps by passing an electric current through them. I also tested the common cotton thread lamps. I passed a current through the lamp and measured the strength of the electric current and the electromotive force. I found that the current was half an ampere, and the electromotive force 50 volts, and the resistance of the lamp, hot, about 100 ohms when the lamp was brought to its proper incandescence.

Did you test it for duration?—No.

Now take the next lamp, marked E G 2. This is a lamp made with cotton thread rubbed with lampblack and tar. I did not measure the resistance of this particular lamp. I saw several of these lamps burning made from the same batch. I did not myself watch them very long, but we have records of the duration made by the last witness. I directed some lamps to be tested for duration. They were made of cotton thread rubbed with lampblack and tar.

What do you say as to the directions given in the specification?—I think they are sufficient to enable a workman to make these lamps. I heard the evidence of the last witness, and I think he proceeded in the right way.

Cross-examined by Sir HORACE DAVEY: I am at present in the employment of the plaintiff company as electrician, and I am well acquainted with the process of manufacture pursued by them.

There are four processes, are there not—carbonising the filament, the flashing process, attaching the carbon filament, and enclosing in the bulb?—Yes.

Is any single one done in the way described in Edison's patent? In the formation of the filament you do not use any single one of the modes suggested by Mr. Edison, do you?—Yes; we use the process which is indicated on page 3, "cotton thread properly carbonised."

But you have a trade secret about that, have you not; it is not a simple cotton thread?—It is a cotton thread which has been parchmentised.

And is that the trade secret connected with this process?—The mode of carrying that out in a commercial manner is a trade secret. The parchmentisation is not described in Edison's specification.

Now, with regard to the method described as carbonising in a close chamber, have you a trade secret with regard to that?—There is a secret in connection with the process of carbonising on a large scale.

As to heating in hydro-carbon, do you practise Cheesborough with something else?—We practise Cheesborough.

Do you use it only for getting your filaments of uniform resistance?—Yes.

Is there a trade secret as to that?—In the process of commercial manufacture on a large scale, to avoid wasters, there are methods employed which are trade secrets.

How do you attach your platina wires—by electro-plating?—It is not attached by electro-plating.

Is it attached in the mode indicated by Edison in his patent?—No.

And that is a trade secret, too?—It is.

Mr. ASTON: Have you any doubt that an incandescent lamp made with a filament composed of lampblack and tar, as described, would be useful?—A lamp so made might be made a very good commercial lamp, in my opinion.

Now, about these secret processes; you say they apply to operations that are carried on on a large scale?—Yes.

With what object are those processes employed?—The object is to save wasters in the manufacture.

Mr. GIMINGHAM recalled, examined by Mr. MOULTON: In addition to the lamp put in before, did you make others, some of which were run for duration?—Yes. [Lamps produced.]

How were they made?—They were made with thread rubbed with lampblack and tar.

And did you abstain from heating during exhaustion, in the same way as the other?—Yes.

In testing for duration, did you run them till they broke down?—Yes, I ran seven together.

What was the average number of hours they stood?—87·5 hours.

What was the longest and what the shortest duration?—The longest was 190 hours, and the shortest 40 hours.

Mr. ASTON: I should have wished to call Prof. Dewar now, but he is not able to be here.

Digitized by Google

His LORDSHIP : We do not want any further scientific evidence.

Mr. ASTON : Then that is the plaintiffs' case. I do not intend to make any comment at this stage. I propose that the judgments in the former case should be brought under your lordship's notice.

Mr. JUSTICE KAY : Those judgments proceeded on other evidence ; therefore, I am bound to make up my own mind on the evidence before me.

Mr. ASTON : I thought those portions of the judgments which refer to the construction of the specification might be useful.

His LORDSHIP : Very well.

The Court then adjourned till Tuesday, April 24.

TUESDAY AND WEDNESDAY, APRIL 24TH AND 25TH.

Sir HORACE DAVEY, opening the case for the defendants, said that he was to some extent in a peculiar position, as an action on the same patents had, as his lordship was aware, been already brought against other defendants by the plaintiff company, and his lordship might perhaps be aware that he appeared on behalf of the defendants. The case against Woodhouse and Rawson went to appeal. Of course, his lordship would form his own decision, but he felt called upon to say that in the first action the defendants relied almost entirely on what was known as Swan's stick lamp as anticipation of Edison's patent, and, depending almost exclusively on the cross-examination of the plaintiffs' witnesses, brought little evidence on their own side. He (Sir Horace Davey) relied on Swan's low-resistance lamp as anticipation, but he by no means relied on that alone. He had evidence which he would bring forward to show that Swan and Stearn not only made, he might say, numerous low-resistance lamps, but that before the date of Edison's application they made lamps with burners of paper or thread, and that these were publicly exhibited. His lordship was well aware that evidence that appeared conclusive in consultation was occasionally liable to fall to pieces under cross-examination in the box, especially evidence of this nature, so he would not at present rely upon it too much, but would wait until his lordship had heard it.

The first case of anticipation that he thought it necessary to call his lordship's attention to was that of King. King used a plate or sheet of carbon made as thin as possible in a Torricellian vacuum. The inventor particularly mentions that the carbon is to be thin, and if it is thin it must have high resistance. The carbon was not in such a perfect vacuum as would now be used ; but the inventor used the best vacuum he could obtain at that date. It must be remembered that the Sprengel pump, which has made incandescent lamp manufacture commercially practicable, was not invented till long after King's time. We have here, then, all the elements of Edison's lamp, the difference being in degree only. The next anticipation is that of an "ingenious gentleman" named Roberts. He used a very thin rod of carbon, supported in a glass bulb by two clamps fastened to leading-in connections. The base of the lamp was not glass, however, but was made of brass, and was connected with a pump by a tube with a stopcock. The most important anticipations were those of Lane-Fox and Swan. He would ask his lordship to turn to Lane-Fox's specification No. 3,988 of 1878. On page 3, line 23, the specification runs :—"The material or alloy employed" (for incandescent conductors) "should be capable of standing as high a degree of temperature as possible without fusing, volatilising, or falling to pieces; it should also have a high specific resistance." Mr. Lane-Fox here points out the very thing on which Mr. Edison lays so much stress in his later specification. "The higher the temperature to which the material can be raised, the more economical will be the light produced—that is, the light will be greater in proportion to the force or energy expended, inasmuch as the radiant energy proceeding from the surface of the material will be more and more luminous as the temperature increases. In order to prevent the deterioration of the material, I sometimes surround it with an atmosphere of nitrogen gas. The quantity of light will be proportional to the extent of the luminous surface. The resistance of the luminous material and its extent of surface should therefore depend on the amount of light it is required to give and the electromotive force used. Speaking broadly, it may be said that the resistance of the luminous conductor should be so adjusted or fixed that the electromotive force of the mains to which it is attached is just sufficient to develop within it the strength of current necessary to raise it to the right degree of incandescence." These passages showed that in 1879 Edison did not discover the laws or principles relating to parallel distribution. Lane-Fox goes on : "In order that the electric force may be conveyed at a higher tension—that is, having high electromotive force, so that there may not be very great loss from the resistance of the conducting mains or conductors—I make the lamps, when I use an alloy of platinum and iridium, of lengths of fine wires, so that I may get a high resistance without having a large extent of luminous surface." Lane-Fox thus clearly explains what is necessary for parallel lighting. If his lordship would kindly turn to Lane-Fox's specification No. 4,043 of 1878, p. 3, he would find the inventor referred to the patent just quoted, and said also :—"I sometimes employ asbestos or other suitable non-conducting refractory material saturated or impregnated with some conducting refractory material, such, for example, as carbon or iridium." In provisional specification 1,122 of 1879 Lane-Fox refers to 140 volts as convenient in the mains, and 300 ohms as a good resistance for the lamp. Mr. Lane-Fox goes on :—"The parts before described are hermetically enclosed within a globe or other form of glass or other suitable material, through one portion of which the conducting wires are hermetically carried. From this globe all trace of oxygen, carbonic acid gas, water, and any gas or vapour capable of attacking or affecting the material of the luminous bridge when at a high temperature must be removed." This last passage has been interpreted to mean that the globe was filled with some inert gas, such as nitrogen, but at any rate it is perfectly consistent with the use of a vacuum.

Mr. Swan's lamp consisted of a conductor of carbon, apparently of low resistance. He understood there was some loose contact now which precluded accurate measurement of the resistance of the conductor. The lamp had had a long litigious life, which had, of course, done it harm. The plaintiffs had held that one of the great advances of Edison, and one of the *differentia* of "filament" was that it was formed before carbonisation. Yet the plaintiffs' witnesses were forced to admit that there were no reasons to suppose Swan's conductor had been made by means of saw and file, and that it might certainly have been made of Carré carbon, as he would prove it really was. The plaintiffs' witnesses were unable to find any evidence of difference between Swan's conductor and Carré carbon, and it was admitted that Carré's carbons were shaped before carbonisation. Sometimes his learned friends held that a filament was a conductor of small cross section. He would ask his lordship to look at the cardboard lamp put in by the plaintiffs as made in accordance with Edison's specification, and claimed by Mr. Imray as an Edison filament lamp. Its resistance was 4·5 ohms, and its surface about the same as Swan's. Swan's resistance was estimated at four ohms. Swan's lamp was, therefore, as much under Edison's claim as the cardboard exhibit, and would therefore invalidate the patent. His lordship would notice that Swan's lamp was to some extent "smoked." This smoking was because Swan did not at that date realise the bad effect of occluded gases in the carbon. He had done so soon afterwards. His lordship would notice, however, that the lamps put in as made according to Edison's specification were also smoked, so that in this respect Edison was just as backward as Swan.

Sir Horace Davey then turned to Edison's own specification, No. 4,576, of 1879. His first objection to this was insufficiency of description. He might, and perhaps would, call many scientific gentlemen who would explain that the instructions were meagre and misleading, but he might also rely on the plaintiffs' evidence alone. In the first place Edison gave no instructions as to how to carbonise. Carbonising such things as charcoal, even for gunpowder, was a known process in 1879, but there was no practice that would guide a workman as to carbonising such things as carbon filaments. This was proved by Sir Frederick Bramwell himself. Even in 1888, here we have Sir Frederick Bramwell, who tells us the workman might use sand. It would have been needless to remind his lordship that sand would most certainly not do. There would be quite enough oxygen in the interstices of the sand to consume a filament entirely, or to injure it and make it inoperative. "Our exceedingly ingenious young friend, Mr. Gimingham," dusted in graphite and bits of broken filament, but he was unable to find any direction to do this in the specification. In answer to an apparently harmless question from Mr. Moulton, the same witness had informed the Court that he wound the cotton thread on a carbon and wood frame, and this he had evolved entirely from his inner consciousness, from his knowledge of carbonisation. This was remarkable, for the wood and carbon frame was an exceedindly ingenious invention, which took some weeks to work out. It was found, after the date of Edison's specification, that the threads contracted so much in the act of carbonisation that they broke. Carbon threads were, of course, obtained, but they were broken and useless for the purpose of incandescent lamps. After many experiments the method of using a frame made of wood and carbon rods was discovered or worked out. The wood carbonises at the same time as the threads, and shrinks with them, so that the threads are not broken during carbonisation, but are kept in shape. Then, on going to the coiled filaments, the witness admitted that it was practically impossible to succeed, though he might have done so if he had had enough time allowed him. That the instructions as to carbonisation are insufficient was admitted, practically, by Edison himself. He had taken out subsequent patents for methods of carbonising. In one case he described elaborate moulds, in which the material or filament to be carbonised was held in such a way that it could contract without spoiling its shape. Now, all this was, according to his view, a tacit admission that his earlier patent, the one now the subject of this action, gave insufficient description. He also took out a patent describing the use of bamboo as a material for the manufacture of filaments. Mr. Edison also shows that his object was not always to make his conductor thin. He wants considerable mass, and wishes to coil the conductor so as to get little radiating surface and large mass. His object was then to make his filament thick. His learned friends were, if he might venture to say so, very slippery. Sometimes a filament was one thing, sometimes another ; but the utmost that had ever been said in the way of definition was that a filament was something of filamentous character. Sometimes a filament must have high resistance, but lamps of a few ohms were included by the plaintiffs as made according to Edison's specification. Sometimes a filament was a thin conductor ; but then they claimed a lamp whose conductor was about as large as that of Swan's stick lamp, and Edison here directs that his conductor may be comparatively thick. Whenever anybody wished to insult Swan's lamp he called it a stick lamp.

Sir Horace Davey asked his lordship to turn to the claims. The first was held by the Court of Appeal to be for a lamp made with the filament as described, and secured as set forth, so that it did not cover other kinds of filaments, or filaments otherwise secured. The second claim covered all filaments. His lordship might, perhaps, be bound to accept the construction of the Court of Appeal as to this claim, unless in this case they brought forward new evidence which would give grounds not existing before for another interpretation. He hoped his lordship might do so.

His LORDSHIP asked whether if Edison had discovered a new principle, and had described one operative method of carrying it into effect, he would be entitled to every other method.

Sir HORACE DAVEY thought he would, provided he had discovered a new principle, but in this case the principle was well known ; so Edison

Digitized by Google

must in his specification give instructions whereby each of several methods of working his invention described may be carried into effect. In the case where the inventor did not discover any new principle, one alternative method that is inoperative would invalidate the patent. He (Sir Horace Davey) read many quotations and cited numerous authorities, such as the aniline case. In this case the patentee directed that a compound was to be treated with sulphuric acid or heated, but it was found to be necessary that it should be heated, it would not work cold, and the patent was held invalid on that ground. If there was any one way in particular which Edison preferred, it was the coiled putty of lampblack and tar. It was the only one described at full length and the only one illustrated. It was also remarkable that Edison did not use the term "filament" till he described his lampblack and tar conductor. Yet this form of all was the most impracticable. The plaintiffs had failed completely to make any such lamp according to the specification. He was instructed that the third claim was for an arrangement which was of no practical use, and was old. The fourth was for the method of securing the filament to the leading-in wires, and he would call witnesses to show that it was inoperative.

Before leaving Edison, he would call his lordship's attention to the fact that, though Edison did not hide his light under a bushel, he had never made any lamps under his specification. In the last case his learned friends had referred to the "world-wide Edison lamp"; and what was the "world-wide Edison lamy"? It was a bamboo lamp made with all the modern improvements worked out by Edison and others, and it was all these innumerable improvements in manufacturing details that made the lamp practical. The first Edison lamps were exhibited towards the latter part of 1881. He would not treat Cheesborough at any great length. He would merely call his lordship's attention to the point that the patent was for a material, not for a process of manufacture. The material was precisely the same as that described by Deprez, and the method of making it was the same. The purpose or application was different, but the claim was for the material, and nothing was said in the specification about the application of it. The patent was also void because the directions were misleading. Cheesborough proposed to enclose a carbon conductor in a tube of lime, and heat it electrically in a carbonaceous gas, so that the carbon would be deposited on the lime. He was instructed that at that temperature the carbon would reduce the lime and be attacked, and the calcium would melt or volatilise, and the process would be inoperative. Cheesborough also proposes to saw or cut up his material into sticks, precisely the mode condemned by his learned friends in the case of Swan's low-resistance lamp.

Mr. ROBERT PERCY SELLON, sworn and examined by Mr. FINLAY, said that he was chief electrician to the Anglo-American Brush Electric Lighting Corporation, and had been engaged on electrical matters for the last eight years or more. He was familiar with the process of the Anglo-American Corporation in making lamps.

What is the material which you take for the manufacture of the carbon used to form the burner?—The material is cellulose in an exceedingly pure condition. It is formed by dissolving ordinary cotton wool in a solution of chloride of zinc. By the application of slight heat this produces a viscous semi-liquid mass.

Mr. JUSTICE KAY: The fibres are dissolved?—The cellular or structural character is entirely destroyed.

Mr. FINLAY: What do you then do with that material?—The material is then forced through a die or small orifice, and is allowed to pass into alcohol. The effect of the alcohol is to precipitate the liquid emerging from the die in the form of a thread.

How is it forced through the die which you have mentioned?—By a pressure applied in any convenient way; in fact, it is applied by a head of mercury.

Before forcing it out in that way, do you take any steps to remove the air bubbles in the viscous mass?—Yes; before passing through the die it is boiled.

Mr. JUSTICE KAY: The air is first removed by boiling the viscous mass?—Yes, with an air pump connected with the vessel containing the mass, which is worked while it is boiling—heating and pumping simultaneously.

Mr. FINLAY: Then it comes out into a thread-like form, and passes out into alcohol, as you described just now?—That is so. I should just like to mention this point, that the effect of the alcohol is not only to stiffen the thread, but to withdraw at the same time the metallic salts—that is, the zinc chloride and any other impurities.

I think you complete the stiffening as well as the removal of any impurities by further steeping in another jar of alcohol for a long time?—That is so; it is left to soak in another jar of alcohol. The result is a non-structural thread of cellulose in an exceedingly pure condition. [A specimen was handed to the witness.] This is a specimen after it has been soaked. It is merely allowed to dry in the atmosphere.

Just explain how the drying is effected?—The thread, while still wet, is wound upon wooden drums, which are covered upon the surface with velvet. A considerable amount of contraction takes place during the drying, and there is sufficient "give" in the velvet to prevent the fracture of the material while drying.

What is the next stage in your process?—The next stage is to wind that material upon a block of plumbago, a specimen of which was shown.

Wound on a piece of cardboard?—A piece of cardboard at the bottom. That is to allow for the contraction, and the form is retained by the cotton thread wound round the block.

To allow for the contraction in a subsequent process?—In a subsequent process of carbonisation.

It ends in a process of carbonisation?—That is so.

That is, by the consumption of the carbon?—By the consumption of the carbon.

Of course, the thread as it carbonises contracts somewhat?—Very considerably.

And the cardboard, which is also carbonised, contracts at the same time?—It also contracts. It consumes away at an early stage of the carbonisation, in fact.

Will you describe now how the carbonisation is effected?—One or more blocks in that form [referring to the specimen already produced] having this material wound upon them are packed upon one another in a plumbago crucible filled with powdered plumbago. A little paraffin wax is placed at the bottom of the crucible. This, by melting at an early stage of the carbonisation, drives off any deleterious gases in the interstices of the plumbago.

Mr. JUSTICE KAY: And replaces them with what?—Paraffin wax is a hydro-carbon, and there would be a combination with the vaporised paraffin wax.

Mr. FINLAY: The crucible of course is closed, and placed in the furnace.—Yes.

How do you apply the temperature, and up to what point?—We commence by applying the temperature gradually. It takes some half a dozen hours to raise the temperature up to a white heat. The object of gradually applying the temperature is that the volatile matters in the carbonisable material should not be driven off too rapidly and deteriorate the carbonisable threads. At the end of the six hours of gradual heating the temperature is raised to the most intense point that the furnace will allow of; that is probably about 3,000° F., so far as one can judge, and that is kept up for several hours.

The total period in the furnace is, I think, about eleven hours?—About eleven hours. The crucible is then taken out to cool, and the plumbago blocks with the carbonised thread upon them withdrawn. The carbonised materials are taken off the plumbago moulds. [The witness produced specimens of the carbonised threads as they are taken off the moulds.] The carbonised thread is then mounted in temporary metallic clips, and subjected to the process of electrical heating in a hydro-carbon atmosphere.

How long do you continue to send the current through the thread or filament in this atmosphere?—The current is only passed through for a few seconds, the object of the process being to obtain relative uniformity of resistance between carbon and carbon.

I understand that to mean you keep the current going until the instrument shows a certain amount of resistance in each case?—We do not actually do that. The current is allowed to pass intermittently; and the resistance, as we practise it, is taken between the intermission of the current while the burner is cold. The current is applied from moment to moment.

If you find that it is not right, do you apply the current again?—We apply the current again.

How do you measure the resistance?—It is measured by an ordinary Wheatstone bridge.

And, then, if it is not right, you do what?—We again apply the current, and again measure the resistance, and that is continued until the desired resistance is arrived at. I may mention that the amount of deposit required to produce this uniformity is really very small, amounting in practice to about 5 to 10 per cent. of the total bulk of the burner. The next step is to "mount," as it is called, the burner upon its platinum wires. The burner is inserted in platinum supports, twisted into a small spiral at the ends. These are specimens of the platinum supports ready to have the burner fixed in. [Producing them.]

Mr. FINLAY: You stick the flashed filament into the spiral?—Yes; these are specimens of the flashed filament. [Producing them.]

Mr. JUSTICE KAY: They look a little lighter in colour and more glossy than the others.—That is the only way in which you can detect the difference. They are a steel-blue-grey, or a steel-grey.

Mr. FINLAY: Having inserted each end of the filament into the spiral, what do you do?—There is temporarily sufficient friction between the ends of the burner and the platinum spirals to hold them, while the point of junction between the platinum and the carbon is heated in a hydro-carbon atmosphere.

Heated how?—Heated electrically by passing the current through the point of junction.

Then this is the second time it is heated in a hydro-carbon atmosphere?—Yes.

What is the object?—The current is, by means of a special mechanica device, prevented from passing in the body of the burner, and in this way only heats the points of junction. As a consequence, there is a deposit over the points of junction only.

Prevents it passing through the thread?—Through the thread proper.

Only through the two junctions?—Yes.

What is the effect of that upon the junction?—The effect is to obtain a deposit of carbon over the point of junction, and so produce a sound mechanical and electrical joint between the two.

The Court then adjourned.

THURSDAY, APRIL 26.

Mr. R. P. SELLON was further examined by Mr. FINLAY, Q.C. He said that after the process of mounting the carbon thread, the next step was the sealing of the carbon thread, mounted upon its platinum wires, into the glass globe. The next step was to exhaust the globe.

Mr. JUSTICE KAY: I do not think you need describe it in detail. At the lower end of the globe there is a tube which is connected with an air pump, and thus the globe is exhausted. Is that so?—Yes, with this addition, that it is first done with a current, and then without a current, the globe being heated externally, that being to dry off the moisture from the inner surface of the glass, and to expand the air. That completes the process.

Digitized by Google

[At this stage a complete globe of the defendants' was produced, shown to witness, and accepted by him as a specimen marked I H 4.]

Mr. FINLAY: You are familiar with the Edison patent which forms the subject of this action?—Yes; I have carried out a considerable number of trials with reference to the processes described.

With what results?—I think the instructions contained in the patent with reference to the manufacture of carbon filament lamps are quite insufficient to enable the workman to make a practically useful lamp.

Which of them have yon tried?—I have tried the whole of the processes except as regards the winding of the carbon upon the copper helix described at p. 4, lines 42 to 46.

And what is the result of your experiments—you say the directions are not sufficient to enable the workmen to make a useful lamp?—Quite insufficient to do so.

Do you produce any specimens of your attempts to carry out Edison's directions?—I have some specimens with me.

Produce them and explain the different processes to which each relates?—I wish to explain that as regards the suggestions towards carbonising described by Mr. Edison, I do not think that workmen would have known in December, 1879, that it would have been necessary to pack the crucible with some material that would prevent the destruction of the carbon burners. When you are dealing with this very slender carbon in incandescent lamps the most rigid exclusion of air is essential; but this is not necessary in the processes of carbonisation as practised in other manufactures. Packing the crucible for carbonising carbons for incandescent lamps with sand would result in the destruction of the carbons.

I ask you the result of your own experiments in endeavouring to carry out Edison's directions in the specification?—In attempting to make lamps in accordance with Edison's instructions I packed the crucible in which the threads and other materials are placed with plumbago, knowing that in the absence of that there would be total destruction of the materials. I produce some samples of cotton threads smeared with lampblack and tar, of paper, and of wood splints, carbonised under these circumstances, and following Edison's directions. The result, so far as the process of carbonising is concerned, has invariably been this, that all the materials mentioned have come out of the carbonising process extremely fragile and roughened, and it was impossible practically to manipulate hem.

You produce specimens made under different processes?—Yes.

They would, I suppose, fall under two groups—fibrous material, such as wood, paper, cotton and thread as the first group; and, secondly, the group where such materials as lampblack and tar are used?—Yes. There are, no doubt, two distinct groups—one which Edison described as fibrous vegetable substances, the second would be lampblack, tar and putty materials. I have numbered the specimens. Nos. 1 to 6 are specimens of carbonised wood splints. I selected boxwood for that purpose, that being the material that would be likely to succeed where a great many others would inevitably fail. In boxwood there is a comparative absence of resinous tarry matter. Nos. 7 and 10 inclusive are cotton threads. They are not smeared or treated in any way. Nos. 11 and 16 inclusive are of paper. Nos. 17 and 18 are cotton threads smeared with lampblack, tar, or putty material.

Would you describe how you treated these various threads?—I carbonised them at a temperature as nearly as I could attain just below that of melted copper. I infer that that was the temperature intended by Edison, from the fact that he says he winds the cotton thread on a copper helix, and afterwards it is eaten away by means of acids.

What is the temperature at which copper will fuse?—2,200° F. In every case the junction with the platinum wires was made in the manner suggested by Edison by pasting the material round the joint.

In any case were you able to get results of practical utility?—In no case. There are several elements of failure, if I may say so, in the process which he describes. Firstly, there is that of carbonisation. Apart from the question of packing with some material, such as either charcoal or plumbago, it is necessary for the production of carbon of any practical value to place them upon moulds, or under some pressure which enables them to retain their form, and which will at the same time permit of the considerable amount of contraction which these vegetable matters undergo during carbonisation.

Is there anything directing that in Edison's specification?—I can find nothing.

And in 1879 would an ordinary workman have known that?—I do not see how he could possibly have known it, having regard to the fact that the carbonising of these slender materials for the purpose of incandescent lamps was quite unknown. When I say unknown I mean it was not commonly known. There were, indeed, several workers who had been engaged on this same question. Among them I name Mr. Lane-Fox and Mr. Swan and Mr. Carré, but it was not common.

Were there other causes of failure?—There is another cause of failure, also common to all the materials suggested in the process of Edison, and that failure is when the platinum wire which is used undergoes the process of carbonising an alloy of platinum is formed. There is a chemical action set up between the platinum and the carbon in the crucible.

That is in the process of mounting?—Yes.

Mr. JUSTICE KAY: What is that alloy?—I believe it is carbide of platinum.

Mr. FINLAY: I understand the effect of this is that the platinum is rendered very porous and rough in character?

Mr. JUSTICE KAY: Is that at the joint?—Witness: The whole of the platinum in the crucible has been subjected in this experiment to the process of carbonisation. The platinum is in this way rendered very brittle, and it becomes very difficult to seal into the glass globe. But even assuming that you succeed in sealing the platinum into the globe, there is great difficulty. I will not say it is impossible, for I have not had a sufficient number of lamps to be able to say so, but I have seen the platinum put into the glass globe, and from the porous character imparted to the platinum you could not obtain a vacuum. That has been upon our usual mercury pumps, and the process of exhaustion has been carried on for a far longer period than is usual with Edison's lamps.

Mr. FINLAY: What is the result?—We find it is impossible to obtain a vacuum. We tried it sufficiently long to convince ourselves that no kind of vacuum would be formed.

Is that the result of putting into the carbonising chamber the carbon wires with the threads mounted upon them as Edison directs?—That is so.

Those two causes of failure you have mentioned are common to the specimens you have produced—fibrous and non-fibrous?—Yes. With reference to this particular exhibit (showing exhibit), box wood, horse-shoe shaped, there is nothing in the samples beyond that the carbons are extremely fragile and roughened on the surface, and in only a very few cases did I succeed in obtaining a complete lamp, consisting of wood splint fixed upon this platinum after the process of carbonisation was over. In the majority of cases the wood has been broken away; and the same remarks apply to the cotton thread and to paper, and there is that element of failure which would certainly stand in the way of enabling a practically useful lamp to be produced from these materials. Vegetable substances, especially those which have undergone a process of manufacture, such for example as cotton thread and paper, contain a great many impurities of various kinds—silica and so on. Unless some precautions are taken to free the material as far as possible from these impurities, such as the process of parchmentising, there is, no doubt, a chemical action set up in the process of carbonisation between those impurities, the cotton threads themselves, and the other materials with the carbon. This results in there being obtained from the carbonising furnaces something very fragile and porous, or coarse-grained in character. And one may say the inevitable result of this must be that when the current is passed through it, it will heat and exhibit bright spots, and in addition to this it will be virtually impossible to get incandescent lamps made out of such materials without what is called running, *i.e.*, yielding a small illuminating power when placed upon a single source of electricity or generation with a dynamo machine. I feel sure that this difficulty is a very real one, from the fact that I am aware—and I believe I know broadly the processes employed in the manufacture of all the best lamps—that no practicable lamp has been made or placed upon the market in which some such process as that of parchmentising has not been adopted. I would wish to add that the remarks which I have been making apply to two lamps made particularly of cotton thread or paper. I am well aware of what is known as the Edison lamp; a lamp made of bamboo fibre has not, to the best of my knowledge, such a process as parchmentising. I believe the bamboo was used direct. With reference to the lampblack and cotton filament, I think it would be absolutely impossible, by following out this process of smearing with putty before carbonisation, to attain results such as I understand Edison to desire to any practical extent.

Mr. FINLAY: Amongst your specimens I do not observe any filament made of lampblack and tar, as suggested by Mr. Edison at page 4, line 1 and following lines?—I have no specimens here, but I may say I have made a great many experiments with the object of testing the practicability of that process.

Mr. JUSTICE KAY: That is what we call the putty filament?—Yes, the putty filament. I followed out Edison's instructions by previously igniting the lampblack in the closed crucible for several hours, as directed at page 4, line 2.

How could it be ignited for several hours?—Well, that is a wrong expression. I afterwards moistened the lampblack with tar, and kneaded the whole until it became thick putty. I endeavoured to roll out pieces of this material in the form of wire to $\frac{1}{1000}$th of an inch in diameter, but the result of all my trials was that the smallest diameter I could obtain before the material cracked and broke into small fragments was about $\frac{1}{100}$th of an inch. I then endeavoured to form these into a spiral, taking Edison's drawing as a guide. Obviously, for the purpose of Edison's spiral, the diameter of the cords must be small, and the convolutions must be close together. All my attempts to obtain a spiral in this form, however, failed, owing to the fact that when the putty was rolled round the small diameter it cracked all through and broke, *i.e.*, it became covered with small cracks.

Mr. JUSTICE KAY: Do you mean it separated?

Witness: It broke in two before I could obtain a spiral of such a form as Mr. Edison describes and shows. I then formed this material into the horseshoe form in order to surmount the difficulty of the crack which resulted from the winding of the spiral. I joined these, mounted them on platinum wires by means of the putty material, moulded round the junction before using, making the junction itself of putty and carbonising it under conditions as regards diameter described by Edison. The result in every case was this—the horseshoes were obtained in an extremely friable condition, so that in many cases they would break on merely lifting them out of the crucible. But in every case, after succeeding in obtaining them from the crucible, they were so extremely fragile that the amount of rough handling that they would ordinarily have to undergo in the subsequent processes of the manufacture of the lamp would almost inevitably break or fracture the horseshoe.

Mr. FINLAY: In your judgment is it possible to make a practicable filament with lampblack and carbon on Mr. Edison's plan?—No.

You have observed what Mr. Edison says about the importance of the spiral form in his specification?—I know he does attach great importance to it.

Have you tried to make filaments other than the filaments of the putty into the spiral form under Mr. Edison's directions?—I have tried the processes which Edison suggests at page 4, lines 9 to 12, *i.e.*, rolling the thread within the putty, but the result was substantially the same as where the putty alone was made use of. It is perfectly true the carbon

Digitized by Google

filament is not so liable to crack, rather less liable than the other ; but nevertheless, the material that was upon the thread did crack in every direction, so that it was quite impossible to obtain any practical result.

I think you have prepared a lamp according to Edison's specification as regards the cotton thread ?—Yes (lamp produced). That is the cotton thread alone not parchmentised. Parchmentisation is obtained by treating with sulphuric acid.

Did you put the thread upon a model in the crucible in this case ?—No, this was not fixed upon any model.

What do you say is the result ?—I wish to explain that the process of mounting has not been carried on according to Edison's instructions. The instructions have only been followed as regards the cotton thread alone in the way I have described, and the result has been a burner of a very porous and rough character, and is absolutely wanting in stability to an extent that would render it useless for practical purposes.

Have you tried camphor and oxide of zinc ?—Yes.

How did that answer ?—The result was, when a current was passed through the lamp, the oxide of zinc and camphor combined with the carbon produced carbonic acid, and the metallic base was reduced and volatilised and the surface of the globe obscured, and the resulting carbon was extremely porous and open grained. Such carbon would very soon dis integrate when put into operation. The process could not be used for practical purposes.

You have been familiar with electric lamps in use for a good number of years ?—Yes.

Since 1879 ?—Since 1880.

Have there been in use any lamps made under this patent of Edison's of November, 1879 ?—Certainly not, so far as I am aware.

You are aware of what was being done by Mr. Swan in the matter of incandescent lamps ?—I am aware from what was published of the matter.

Have you made lamps such as were produced by the Attorney-General as samples of his lamps ?—I have. I have them by me.

Can you tell whether you find they worked and how they worked ?—I have produced such lamps as these experimentally, and have tried their working for a considerable number of hours, varying in different cases. I found they worked perfectly satisfactorily as individual lamps.

Mr. JUSTICE KAY : They would not work alongside ?—I mean to say that such lamps, being lamps of low resistance, would not be suited for purposes of distribution where a large number of lamps are being used at distances from the source of generation.

Mr. FINLAY : You exhibit now lamps made according to the model ?—Yes. I did not have the advantage of the model, but they were made in accordance with what I saw of the model and what was published with reference to Mr. Swan's lamp.

What publication do you refer to ?—The lamp was described by Mr. Swan either at one of his lectures or before the Literary and Philosophical Society of Newcastle.

You have seen Mr. Cheesborough's specification, and you have employed the process of flashing ?—Yes ; I have observed the advantages claimed by Cheesborough for the material produced in the way he describes.

Do you employ the process of flashing for that purpose ?—Not for the purpose described by Mr. Cheesborough—that is to say, the main object of the process of electrical heating.

Mr. FINLAY : You have examined and are prepared to show your carbon filaments as they are before and after the process ?—Yes. I have lens which will enable examination to be made on carbon both before and after flashing.

Does the carbon of your filaments require the process for the purpose mentioned by Mr. Cheesborough ?—Broadly speaking it does not. It is so even or dense throughout its length that we have no difficulty, and have actually made lamps without employing the process of flashing at all ; that is to say, there are no inherent defects in the carbon burners themselves, which require to be corrected by this process.

You said, "broadly speaking." Does that mean there is any qualification, and if so, what ?—What I mean to say is this, that the primary object with which we carry out the process is, and is only, that of obtaining relative uniform resistance between burner and burner. It is quite possible, as a matter of fact, that occasionally one in perhaps a considerable number of burners would be obtained from the carbonising furnace which has received some injury. It might have become damaged in some way or other, so that on the passing of the current through it it would be uneven in its cross-section. In such a case the result of subjecting it to the process of electrical heating in carbon gas would be to cure that defect. That is the qualification, but it is quite an exceptional thing.

Would you show a filament under the lens to his lordship ?

Mr. JUSTICE KAY : Better show it to experts.

Mr. FINLAY : You observe the reference to 7,000° F. in Mr. Cheesborough's specification ?—Yes.

What would be the effect of such temperature ?—Obviously the immediate destruction of the carbon subjected to it ; and for this reason, that carbon volatilises in an electrical arc, and the temperature of an electrical arc has been calculated to be about 5,000 or 6,000° F., so that obviously if subjected to a temperature more than 1,000 degrees higher than that it would be instantly destroyed.

What was the resistance of these lamps made by you after the species of Swan's stick lamps ?—Using a carbon of the same length and the same diameter, as nearly as possible to do so, the resistance was I think, between 1 and 2 ohms while cold.

Have you tried the resistance produced as being made by the plaintiffs under Edison's patent ?—I have.

What was their resistance ?—I am sorry to say I have not kept accurate measurement, but I remember clearly that their resistance cold averaged 2½ ohms as nearly as possible.

Mr. Aston, Q.C., asked that as a great deal of the evidence given referred to experiments, he might be allowed to reserve the cross-examination of this witness, but Mr. Justice Kay said he had better go on.

Cross-examined by Mr. ASTON : I understand you to say that you are not familiar with the manufacture of pieces of carbon to be used for electric lighting carbonised in close retorts by means of charcoal ?—I do not mean to imply that I am not familiar with the carbonisation of carbon under conditions where charcoal was used.

I am speaking of 1879.—I was not aware then.

Have you the specifications referred to as the alleged anticipations of Cheesborough's patent ?—I have.

Do you not remember that Stait says that electrodes are improved by being gradually exposed to the strongest white heat of the furnace, enclosed in vessels of charcoal ?—I think he says so.

The learned counsel then read Stait's specification and other specifications, and cross-examined witness with reference to them.

Mr. JUSTICE KAY asked if he was to assume that the contention was that an ordinary workman knew all that was in the book ?

Mr. ASTON said not an ordinary workman, but persons who had to deal with the manufacture of this light brought into use. That, however, would be a matter for argument by-and-bye.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-NIGHT) FRIDAY, April 27th.

ROYAL INSTITUTION.

9 p.m. "Electrical Influence Machines." By Mr. JAMES WIMSHURST, M.R.I.

SATURDAY, April 28th.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Later Works of Richard Wagner" (3). By Mr. C. ARMBRUSTER.

PHYSICAL SOCIETY OF GLASGOW UNIVERSITY.

Paper on "Theory of Gases." By Mr. W. COLQUHOUN, M.A.

PHYSICAL SOCIETY (LONDON).

3 p.m. "On Electromotive Force by Contact." By Mr. C. V. BURTON. "A Theory Concerning the Sudden Loss of Magnetic Properties of Iron and Nickel." By Mr. H. TOMLINSON. Note on "The Graphic Treatment of the Lamont-Frölich Formula for Induced Magnetism;" Note on "The Conditions of Self-Excitement in a Dynamo Machine;" and Note on "The Conditions of Self-Regulation in a Constant Potential Dynamo Machine." By Prof. S. P. THOMPSON.

MONDAY, April 30th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture VI. "The Decoration and Illustration of Books" (1). By Mr. W. CRANE.

TUESDAY, May 1st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed, "The Distribution of Hydraulic Power in London." By Mr. E. B. ELLINGTON, M.I.C.E.

ROYAL INSTITUTION.

1:30 p.m. Annual Meeting.

3 p.m. "The Plant in the War of Nature." By Mr. W. GARDINER.

WEDNESDAY, May 2nd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Drawing, a means of Education." By Mr. T. R. ABLETT. Sir GEORGE BIRDWOOD, M.D., K.C.I.E., C.S.I., in the chair.

THURSDAY, May 3rd.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Chemical Arts" (4). By Prof. DEWAR.

ROYAL SOCIETY.

4:30 p.m. Ordinary Meeting.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting.

SOCIETY OF MECHANICAL ENGINEERS.

7:30 p.m. Meeting at the Institution of Civil Engineers.

FRIDAY, May 4th.

7:30 p.m. Continuation of last-mentioned meeting.

ROYAL INSTITUTION.

9 p.m. "The Invincible Armada." By Prof. J. K. LAUGHTON.

SOCIETY OF ARTS.

8 p.m. Indian Section. "The Injurious Effects of Canal Irrigation on the Health of the Population of the Punjab." By Surgeon-General H. W. BELLEW, C.S.I., C.I.E. Sir JOSEPH FAYRER K.C.S.I., will preside.

,, Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	6 1	...	12 1	...	24 2

"The Electrician" in America.

'THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

CONTENTS OF THE CURRENT NUMBER.

SPECIAL NOTICE.

With this week's issue we present our readers (Gratis) with a Steel Plate Portrait of SIR JOHN PENDER, K.C.M.G.

Complaints of non-receipt should be made *at once* to the Publisher.

THE SIR JOHN PENDER BANQUET.

Less than a year ago a numerous and distinguished assembly met together in the manner customary among Englishmen to celebrate round the festive board the Jubilee of the Electric Telegraph, and to do honour to the memory of its discoverers who had passed away before that era of its existence was reached. Last Monday evening an equally numerous, and, if possible, still more distinguished, gathering joined in a similar demonstration to commemorate the greatest of all the achievements to which that discovery has been applied, and to do honour to one who has been and is still conspicuously associated with its triumphs. Submarine Telegraphy—or more correctly in this relation sub-oceanic telegraphy—is of comparatively recent date, and the successful laying of the cables uniting this country with America marked a totally new departure with an entirely new field of operations for the art which COOKE and WHEATSTONE had given us nearly thirty years earlier. The completion of that difficult and hazardous enterprise, which at one time threatened to sink past recovery millions of English capital at the bottom of the Atlantic, was largely due to the courage, the energy, and the liberality of the honoured guest at last Mondey's banquet. The possibility of oceanic telegraphy on so vast a scale being once established, its extension in other directions had not long to wait. The far East was soon reached; and in due time the Australasian and South African Colonies, as well as our Indian Empire, with all the intermediate links between us and that splendid dependency, were welded together by a chain of inter-communication as effectual and almost as secure as that which had crossed the silver streak which separates England from France.

To all these far-reaching and momentous enterprises, Mr., now Sir JOHN, PENDER, has lent his powerful aid; and it is hardly an exaggeration to say that wherever submarine tele-

Digitized by Google

graphy is known his name will be found associated with it. Mr. JOHN PENDER had earned this world-wide celebrity long before it was publicly recognised in his own country. Honours which are lavishly bestowed for political services are sparingly given to the pioneers of national commerce. Jus recently, however, the QUEEN'S advisers bethought them ot the debt which they owed to this eminent and indefatigable agent in the prosperity of the empire, and HER MAJESTY has been pleased to confer upon him the Order of K.C.M.G. It was to congratulate him upon this well-deserved, though somewhat tardy, recognition of his services that the banquet at the Hôtel Métropole was given; and the proceedings were in every way worthy of the event they intended to celebrate. Perhaps in no other country could such a scene have been witnessed; certainly in no other country is the true value of distinction such as this so frankly acknowledged where at the same time it is as discriminately bestowed. Except for those political services which Lord WOLSELEY evidently holds in very light estimation, and which are peculiar to the parliamentary institutions of this country, honours must be earned before they are had; and every one of the illustrious speakers of the evening gave their ungrudging testimony to the deserts of the man whom the nation has raised to a dignity which, although, as some think, inadequate, is at all events well deserved, and free from what Lord WOLSELEY calls the taint of party politics. The company present on this occasion might have been roughly described as composed of two classes, one of distinguished men who welcomed a fellow worker to their own ranks, the other of men who cheerfully rejoiced in a comrade's promotion from theirs.

Among the former, Lord DERBY, who occupied the chair, paid a very warm tribute of respect and gratitude to Sir JOHN —a tribute all the more valuable as coming from an ex-Colonial Secretary, who, if anybody, should know what submarine telegraphy has done for the Colonies and for England, and none the less genuine for being couched in terms of personal friendship for the recipient. "I ask you," his lordship said, "to join with me in paying this mark of respect to a gentleman whom many of us have known long as a private friend—few, I think, longer than I have—and whom all of us know in his public capacity; to one who has been prosperous enough, I have no doubt, to excite something of that jealousy with which marked success is apt to be attended, but who has attracted in this room a body of friends, which, whether we look to mere numbers, to social importance, to intellectual power, or to the warmth of their attachment, forms such a gathering as has seldom come together in honour of any private individual." Success, as the Chairman afterwards remarked, is not always a sure test of merit, nor failure of demerit; but in this case it was felt both by speaker and audience that the successes were not more remarkable than the qualities by which they had been achieved. These qualities are represented in the best traditions of British commerce and enterprise. It is to the exercise of these qualities that Sir JOHN PENDER owes his prosperous career, and we the prosperity of oceanic telegraphy There need be no illusions on this point. Whatever the State may think fit to do with its inland telegraphs, or with those connecting it to its immediate neighbours, the cable business of the world will probably remain in private hands. At all events, it has never yet been undertaken by the State; and never by anyone, unless for those sound commercial reasons which have impelled men like Sir JOHN PENDER to embark their energy and their capital in ventures which yield a profitable return. These are not the men of "fixed ideas" of whom CARLYLE bids us beware. Their aims are tangible realities; and what they have accomplished is equally removed from the fanciful and ideal.

A passing reference to this aspect of submarine telegraphy was made by Sir JOHN PENDER himself in his response to the toast of the evening. Although, said he, we have laid enough cable to girdle the world many times round, we have not put a girdle round it yet, simply because in our judgment the girdle would not pay. The fancy of a SHAKESPEARE may picture it there, and the "fixed idea" of the member for Canterbury may persist in fixing it there, but for the present cable enterprise must continue to be, as in the past it has been, conducted on sober and matter-of-fact business principles. Incidentally, no doubt, the existence, and possibly the extension, of submarine telegraphy will lend itself to a more sentimental purpose—to solve the great emigration question, for example. It was said by Sir JOHN that the fact of a colony being within speaking distance of the mother country may help to reconcile the surplus populations to the expatriation which in these days they seem so loth to incur, and no doubt this is the case. It will also assist more than anything else can do to bring about, if it has not already created, a practical Imperial Federation, which is the "fixed idea" of so many eminent enthusiasts. Of one thing we need entertain no doubt whatever, although Lord DERBY is not quite sure about it. Whether we, the people of the world, will love one another the better for being so intimately associated is to him an open question. But if the invention of printing made us more sympathetic, more humane, as one of the shrewdest of English novelists once assured us that it did, we may confidently predict a similar effect from the even wider sympathies which the world's telegraphs open up to us. On the whole, and in the long-run, as MATTHEW ARNOLD used to say, the telegraph "makes for" peace by promptly removing the causes of discord. To quote again from CARLYLE, "all quarrels are at bottom the result of misunderstandings;" and nothing contributes to the clearing up of misunderstandings between distant disputants so quickly as the telegraph. If Sir JOHN PENDER had no other title to fame than that of doing so much as he has done to put the world on this friendly footing, the honour lately conferred upon him would have been abundantly earned.

ELECTRIC TRACTION ON THE UNDERGROUND RAILWAY.

A few days since the *Financial News* informed its readers that the Metropolitan District Railway Company was "negotiating an arrangement for the working of its engines by electricity." This important statement will not, however, be new to the electrical world, since we first hinted at the existence of such a scheme more than six months ago, and in our issue of 20th January were able to give further details. It needs no argument to convince a Londoner that the successful adoption of electric traction upon the Underground Railways would immediately be followed by a large increase in the traffic receipts, and any scheme which will alleviate the miseries of the long-suffering millions who daily traverse those dark and dismal regions must command the attention of a very large section of the community. If, in addition, it can be demonstrated that the cost of working the line will be materially diminished, then there would appear to be nothing lacking on the part either of the public or of the railway directors to hasten the inauguration of this much-needed reform.

On the other hand, everyone must recognise that the commencement of anything in the nature of an experiment under the actual working conditions of the Metropolitan Railway is

Digitized by Google

a matter requiring the most attentive consideration and the utmost possible care and skill in the arrangements. It is not our wish, therefore, to urge anything like undue haste in the matter, nor is it our intention at the present moment to enter upon a technical discussion of the various possible solutions of the problem which present themselves to the electrical engineer. We wish, however, to submit in very few words some considerations which may tend towards a more rapid and more successful solution than our knowledge of the actual position of affairs leads us at present to anticipate.

It will be within the recollection of our readers that the proposal, which is still under consideration, involves the employment of secondary batteries, and it is quite possible that the promoters of the scheme have not as yet fully satisfied themselves as to the best form of cell for the purpose in view. However this may be, it is easy to understand some of the reasons which have led to the selection of the battery system as the most readily available for a preliminary experiment. The leading idea probably is that the self-contained electric engine, when its development had been perfected, would be able to run in turn with the ordinary traffic without requiring the least modification in the present arrangements. On the other hand, there are very few electrical engineers who would refuse to admit that, if once the experimental difficulties could be overcome, the adoption of a method of working by direct transmission from dynamos is peculiarly well suited to a railway line of this description. That the economy of this scheme would necessarily be higher than that obtainable by means of batteries scarcely requires demonstration. Apart altogether from the question of efficiency and duration of the cells, we must recollect that the batteries have to drag their own weight as well as that of the train; what this implies, where sufficient power has to be provided for starting the train every few minutes, only electrical engineers are in a position fully to appreciate. Our remarks on this point, however, must not be taken as antagonistic to the employment of secondary batteries where their efficiency and economy are beyond dispute.

Now, it seems to us that the difficulty of making a practical experiment with any one of the numerous overhead or conduit systems (which have proved so successful in the United States) may quite easily be overcome. We may add, parenthetically, that the Company which has the matter in hand is undoubtedly as well able to carry out a scheme of this character as the one already proposed. The suggestion which we would venture to make is, in brief, the following:—Let a certain section of the line be provided with conductors, either suspended from the roof of the tunnel or laid between the rails, as may be deemed most convenient. Let a certain number of the trains be provided with an electric locomotive *in addition* to the steam engine. It is obvious that the train could then take its place upon the circle with the rest of the traffic, without the least danger of causing an interruption, the steam engine taking it over the ordinary part of the line, and the electric locomotive doing duty on the electrical section. Over the electrical section the steam engine would, of course, form part of the load to be drawn; but that would enhance the value of the test. Such an experiment as this might be inaugurated at a minimum cost, and could be gradually extended over the whole system as experience and confidence were gained. While frankly confessing the experimental character of these praliminary trials, we are thoroughly persuaded they would result in the removal of any difficulties which at present seem to stand in the way of their success. In the interests alike of the shareholders and passengers of the Metropolitan and District Railways, as well as in those of Electric Traction in general, we trust that the experiment will speedily be made.

BANQUET TO SIR JOHN PENDER, K.C.M.G.

In recognition of the prominent part which has from the outset been taken by Sir John Pender in submarine telegraphy a banquet was given in his honour last Monday evening at the Hôtel Métropole by his friends, principally gentlemen who have been associated with him in the progress of this important enterprise. An extremely interesting feature of the evening's proceedings was the presentation to Lady Pender of a portrait of her husband, Sir John acting as intermediary for her ladyship. The portrait has been painted by Professor Herkomer, and was generally admired.

A large and distinguished company assembled to do honour to the occasion. The Right Hon. the Earl of Derby, K.G., presided, the guests including His Excellency Count van Bylandt, His Excellency Count Piper, the Earl of Jersey, Earl De la Warr, Lord Esher (the Master of the Rolls), General the Right Hon. Viscount Wolseley, G.C.B., G.C.M.G.; Lord Stratheden and Campbell, the Right Hon. Viscount Bury, K.C.M.G.; Lord Chelmsford, G.C.B.; Lord E. G. Fitzmaurice, Viscount Lymington, M.P.; Lord C. J. Hamilton, M.P.; the Right Hon. Sir Henry James, Q.C., M.P.; the Right Hon. C. H. Raikes (Postmaster-General), Sir Lyon Playfair, M.P., K.C.B.; Prof. Ayrton, Dr. Priestley, Mr. Robert Browning, Sir George Elliot, Bart., M.P.; Sir John Hawkshaw, F.R.S.; Sir Stevenson A. Blackwood, K.C.B.; the Right Hon. Sir H. Selwin-Ibbetson, M.P.; and Count Oscar Von Reichenbach. The other gentlemen present, including those forming the committee who promoted and carried out the arrangements of the banquet, were:—Sir James Anderson, W. Andrews, Esq.; Arthur Anderson, Esq.; Kenneth Anderson, Esq.; W. T. Ansell, Esq.; Ben. Ashton, Esq.; Dr. Aikin, the Hon. Wm. St. John Brodrick, M.P.; F. A. Bevan, Esq.; A. H. Berthoud, Esq.; F. W. Bond, Esq.; J. Spencer Balfour, Esq.; the Very Rev. Geo. G. Bradley, Dean of Westminster, D.D.; F. E. Baines, Esq., C.B.; T. Brown, Esq.; W. H. Burman, Esq.; Chas. Burt, Esq.; Sir Arthur Blyth, K.C.M.G., C.B.; G. C. Bompas, Esq.; Sir Graham Berry, K.C.M.G.; J. Bass, Esq.; F. A. Beer, Esq.; Sir F. Dillon Bell, K.C.M.G., C.B.; Major-General Beadle, R.E.; T. G. Bowles, Esq.; Right Hon. Hugh C. E. Childers; Lord Sackville A. Cecil; G. W. Campbell, Esq.; R. M. Cunningham, Esq.; Richard Collett, Esq.; Sir A. L. Cappel, K.C.I.E.; Sir Daniel Cooper, Bart.; Sir Philip Henry W. Currie, K.C.B.; Latimer Clark, Esq.; H. Clifford Esq.; Alexander Crum, Esq.; the Hon. Ralph Dutton; Sir Juland Danvers, K.C.S.I.; Sir H. Des Vœux, Bart.; Edward J. S. Dicey, Esq., C.B.; George Draper, Esq.; E. Dickens, Esq.; R. Dudley, Esq.; E. Duncanson, Esq.; Capt. Davies, Herbert de Reuter, Esq.; C. W. Earle, Esq.; H. G. Erichsen, Esq.; Sir Henry Edwards, the Baron Erlanger, T. Fuller, Esq.; William Ford, Esq.: J. Staats Forbes, Esq.; L. Floersheim, Esq.; H. C. Fischer, Esq.; T. Finnis, Esq.; Henry C. Forde, Esq.; W. Flux, Esq.; C. J. Günther, Esq.; Matthew Gray, Esq.; Sir Gabriel Goldney, Bart.; Thos. Gray, Esq., C.B.; E. Graves, Esq.; Colonel Gouraud, Ch. Gerhardi, Esq,; Sir James F. Garrick, K.C.M.G., Q.C.; H. R. Grenfell, Esq.; J. G. Griffiths, Esq.; Earl of Galloway, K.T.; Admiral Sir Leopold Heath, K.C.B.; Admiral Sir J. C. D. Hay, Bart.; H. Holmes, Esq.; W. G. Hall, Esq.; F. E. Hesse, Esq.; A. R. Hardie, Esq.; J. C. Harker, Esq.; Sir Robert Herbert, K.C.B.; Admiral Sir Anthony H. Hoskins, K.C.B.; Captain Halpin, J. T. Horley, Esq; Keeley Halswelle, Esq.; F. Higgins, Esq.; Ludwig N. Hardy, Esq.; Sir J. Pope Hennessey, K.C.M.G.; W. Hibberdine, Esq.; F. A. Inderwick, Q.C.; Gen. Johnston, C.B.; F. J. Johnston, Esq.; W. Claude Johnson, Esq.; Admiral of the Fleet Sir H. Keppel; C. M. Kennedy, Esq., C.B.; L. Loëffler, Esq.; H. W. Lucy, Esq.; E. L. Lawson, Esq.; C. W. Lundy, Esq.; J. Laister, Esq.; John Latey, jun., Esq.; Admiral R. C. Mayne, M.P.; A. Marshall, Esq.; Peter M'Lagan, M.P.; Sir Halliday Macartney, K.C.M.G.; J. H. Macdonald, Esq. (the Lord Advocate); James McDougall, Esq.; Sir Chas. Mills, K.C.M.G., C.B.; J. Muirhead, Esq.; Dr. A. The "Health of Her Majesty the Queen, the Prince and Princess of Wales, and the other members of the Royal Family" having been drunk with the customary enthusiasm,

LORD DERBY proposed "The Army, the Navy, and Volunteer Forces," coupling with the toast the names of General Lord Wolseley, Admiral Sir Leopold Heath, and Viscount Bury.

The toast having been duly honoured,

LORD WOLSELEY said: Lord Derby, my Lords, and Gentlemen—I have very great pleasure in speaking on behalf of the Army, and in returning you thanks for the cordiality with which this toast has been received; and I am very much obliged to you, Lord Derby, for the very kind manner in which you have personally referred to me. I am very glad to have this opportunity afforded me of speaking on behalf of the profession to which I have the honour of belonging, and to convey an expression on their behalf of gratitude to the guest of this evening, Sir John Pender, for the great kindness we have always received from him and from the companies over which he has so ably presided for so many years. During all the recent little wars we have had in various parts of the world, wherever it has been my good fortune to come in contact with Sir John Pender he has invariably aided and assisted us, not only publicly, but privately, and has done everything he possibly could do in the interest of the public service, and has invariably on all occasions told me whenever I have been drawn into contact with him that he would use every effort to assist private individuals—that is, the sick and wounded—by freely placing the telegraphs with which he was connected at their disposal (cheers). It is no easy matter for an officer holding a public position, as I do, in the War Office, to speak in an open manner about the Army. Of course it is possible to speak on various subjects connected with the discipline of the Army and its organisation and its reorganisation, which has gone on for so many years; but it is no easy matter to speak as I would wish to speak, "from the housetops," about the Army, and not overstep the bounds which a public officer should do. As regards the ordinary affairs of the Army, I think I am justified in saying that in no previous period of our history has it been, as far as it goes, in a more efficient condition (cheers). I believe that officers are far better instructed, far more able to undertake the duties they are called upon to perform, and far more efficient to discharge those duties than I have ever known them (cheers). Now I will mention to you one fact which has lately come to my notice, which speaks volumes for the discipline of our men—that during the last twelve months half of our military prisons have been shut up because we had no one to send into them (cheers). Under our peculiar system of Government it is very difficult indeed, as I have said, for an officer to speak regarding the organisation of the Army, but it is no easy matter to have really an efficient Army at all. It is very curious that though John Bull goes to considerable expense in paying those whom he considers experts to advise him and the country both on the Army and the Navy—admirals and generals who advise him on naval and military matters—that the opinions of those experts, which are so highly praised, are never published, and John Bull, who pays for them, is never made acquainted with what those opinions are. We have from time to time long statements made as to the Army and Navy from gentlemen in power. I have often to listen to them myself, and I often wonder how much those speeches are affected by the Party exigencies of the moment, and how much they represent the opinions of the First Lord of the Admiralty and of the Secretary of State for War. I confess myself that this is a system of which I cannot approve, and I do not believe that any Admiral or General in office, or who has been in office, approves of it, because one and all of us believe that it is a system which sooner or later will land this country in disaster. We live in times when, I think, it behoves the people of England to know not only the truth, but the whole truth, with respect to its Army and Navy (cheers). We see around us all the nations of Europe—certainly all the great nations of Europe—with the one exception of England, armed to the teeth; and as you look around on the political horizon of Europe you can gather no good from it, but it all forebodes storms, and certainly forebodes no good for this country. Those who, like myself, have to study matters connected with the defences of this Empire, not only at home but abroad, have to put this question to ourselves—Are the Army and the Navy as strong as they ought to be? I think very few who have studied this question would admit that they are as strong as they ought to be. But when we come to think why they are not so strong as they should be, surely, as Lord Derby has said, the people of this country have never refused the Ministry any money they have asked for, either for the Army or the Navy; and surely the taxpayers of this country never grudge any money which they are asked to pay for the efficiency of those services. The answer to the question, why the Army and the Navy are not as strong as they ought to be, is to be found in the system of our Government in Party politics—that curse of modern England which is now sapping and undermining the foundations of our country, and which is depriving our statesmen of the manly honesty which was once their characteristic. What do we see when any new Administration comes into office? What directly takes place? It is the same with all Parties. The first thing is the endeavour made by the Minister in office to obtain some clap-trap reputation by cutting down the expenses of the Army and Navy, and when some Minister is enabled to produce an Army and Navy Budget which in some degree represents a smaller sum than that of his predecessor he plumes himself upon the victory he has gained. He is proud that he has succeeded better than, perhaps, his opponent who sits on the bench opposite him, and as he chuckles over this success he says, "See what a good boy am I!" (laughter and cheers). This is the result of—what? The result of a low and vicious standard of morality, which is now uppermost in men's minds. In speaking so light-heartedly of such a matter he forgets, in his pride of having reduced the Estimates, the fault he has committed, the crime he is guilty of against the country (cheers). I hope you will pardon me for speaking so openly as I have done, but I feel deeply on the subject. I feel that we have arrived at an epoch in our history when it behoves public men to speak the truth, and not only the truth, but the whole truth (cheers).

ADMIRAL SIR L. HEATH, in replying for the Navy, said that his profession were very proud at having been associated with the very early days of ocean telegraphy, and they were grateful to those who, with such energy, perseverance and scientific skill, had covered the ocean with their lines.

VISCOUNT BURY replied for the Auxiliary Forces.

LORD DERBY: Sir John Pender, it now devolves upon me to perform a very agreeable duty, and that is to ask you to act as an intermediary for Lady Pender, and on her part to accept from the committee and from your friends who have met in this room the picture which we now see on the opposite wall (cheers). Of that work of art I will only say that it seems to me that the executioner has done full justice to the merits of the subject. I shall immediately proceed on another and not less agreeable task, and that is to propose to you, my lords and gentlemen, the toast of the evening and to ask you to drink the health of our honoured guest and friend, Sir John Pender (cheers). I shall say what I have to say in a few words, and that for several reasons. A tolerable acquaintance with public dinners has taught me that while many speeches are complained of as being too long, none in my recollection was ever complained of as being too short (laughter). That is one reason. Another is that to speak of a distinguished man in terms which one would like to use is easier in his absence than before his face; and this I know, that if my part should be imperfectly played, your sympathy and goodwill, acquired beforehand, will more than supply its deficiency. I ask you to join with me in paying this mark of respect to a gentleman whom many of us have known long as a private friend—few I think longer than I have—and whom all of us know in his public capacity, who has been prosperous enough, I have no doubt, to excite something of that jealousy with which marked success is apt to be attended, but who has brought together in this room a body of friends, which, whether we look to mere numbers, to social importance, to intellectual power, or to the warmth of their attachment, forms such a gathering as has seldom come together in honour of any private individual (cheers). Our friend, as we know, has been the author of his own fortunes, but I am not asking you to pay him honour for being what is called a self-made man. There are many kinds of self-made men, and the value of the article so produced varies greatly. We have heard of some who by the fact of having made themselves have been said to have relieved Providence of a heavy responsibility (laughter). Success is not a sure test of merit, nor failure of demerit; but when we find large means obtained by the industry, the energy, the adventure, and the foresight of a lifetime—when we find a man who has so thriven giving the best of his time and his care to the service of the public; when we know that he employs in liberal hospitality, in the patronage of science and art and the encouragement of industrial enterprise, the fortune which he has acquired, we cannot refuse to pay respect, not to the success which has been achieved, but to the qualities by which it has been earned; not to the wealth which has been accumulated, but to the wise and generous use which has made that accumulation a public benefit and not a public injury (cheers). But, gentlemen, it is not of our friend as a man of business, it is not even of him in his capacity as a former member of Parliament, that I am here to speak to-night. I sat long enough with him in the House of Commons, though not then in the same political connection, to be able

Digitized by Google

to bear witness to the respect which was always felt there for his opinion when he chose to give it, and it is something to say of a member of Parliament that he never, so far as I know, made an unnecessary speech or made a speech which did not tell the House something worth knowing (applause). But it is not on the ground of public service that Sir John Pender's name will be entitled to the gratitude and respect of future times. His main work as regards the public is in that field which for many years he made, I will not say exclusively, but principally, his own—I refer, as, of course, you know, to the service which he has rendered to submarine telegraphy (cheers). Of that great branch of enterprise it is not too much to say that he has been the principal promoter (cheers). He was chairman of the British and Irish Magnetic Company at a time when the public idea of carrying wires under a vast stretch of ocean was altogether new and strange. He was one of the largest contributors to the first Atlantic cable projected. He came to the rescue at the moment of greatest difficulty, when the first Atlantic cable parted in mid-ocean, and the company which sent it out could do nothing more. It would have been useless at that moment to appeal to the public. They had been in general mistrustful from the first, and they were utterly disgusted by the failure. It is not too much to affirm that, but for Sir John Pender and for a few others of whom he was the chief, that enterprise would have collapsed, and at best a long delay would have occurred before investors consented to risk their capital in such a speculation again. Of course the thing would have been done at last (Sir John Pender: Hear, hear,) just as some one, no doubt, would have discovered America if Columbus had failed (laughter), and just as the steam engine was bound to come into existence if James Watt had never been born. Great discoveries, great inventions, important applications of science to new purposes, cannot be long delayed or long thwarted by the action of an individual, but in such a case as this the loss of time represented by even one generation would have meant almost incalculable loss—material loss—to England; and very likely the Americans, or some other energetic people, would have come in, and would have taken the lead and all the glory and profit out of our hands (hear, hear). I will not go into details here, but I will state only what is publicly known when I tell you that in order to avert a failure, which would have led to the loss of all the capital employed, Sir John Pender gave his personal guarantee for a quarter of a million sterling (loud cheers). That practical evidence of confidence created confidence in other people. The work went on again; a new cable was laid, and by what I have always thought the most singular triumph of scientific ingenuity, the old cable was recovered from the depth of the Atlantic, some two miles below the surface (applause). We have heard of capital sunk in an industrial enterprise; but it does not often happen that capital sunk at such a depth is recovered (laughter and cheers). Well, if our friend had done nothing more than what I have told you he would still have been the greatest benefactor to the cause of telegraphy that had yet appeared. But with him this success was only the beginning. He was not content to win a victory—he knew how to improve it when won. He became chairman of the company that laid the first line to India; he controlled the line giving independent communication to Gibraltar, Malta, and Suez; he created the present Eastern Telegraph Company, giving access to the whole of the Levant; he was mainly instrumental in establishing communication with Australia and China; and, not least important, he gave us the cable to South Africa, which, if it had been in existence a few years earlier, would have saved us an outlay larger than I like to contemplate, both in lives and in money (cheers). No doubt he has not done these things alone. Others have helped, and helped largely (Sir John Pender: Hear, hear), but I am sure I shall not be contradicted when I say that those who have the best right to participate in the credit would be the readiest to award to our friend the largest share of it (cheers). Sir John himself will tell you better than I can do what the results of telegraphic work have been, but I think I am right in saying that the submarine cables now in use would go five times round the globe, and that more than nine-tenths of them—which to my mind is a more important matter—have been laid by private enterprise, leaving less than one-tenth as the work of the State (cheers). In regard to military matters, the saving of force effected by ocean telegraphs is obvious, and is immense. If troubles occur in India, in South Africa, or elsewhere, troops can be on the spot in less time than it would have formerly taken for the news to reach England (applause). Wherever our fleets or our armies may be, they can be put under orders from home at a few hours' notice. To any country that would be a considerable gain; to a country whose interests and responsibilities are scattered over the world, as ours are, the gain is incalculable and invaluable (cheers). But the administrative changes brought about are perhaps not less important. We have now, for the first time, an effective control over the men whom we send out to govern distant dependencies. It is something almost unintelligible to us now the way in which in the early days of Anglo-Indian history wars were entered into, treaties concluded, and territories annexed, all in the name of England, by English arms, all at England's expense, without the people at home—even those in authority—having a chance to speak on the subject. The thing was done, and in Leadenhall-street and Downing-street it was first heard of months after it had become an accomplished fact. I am bound to admit—and you may draw from the admission what inference you please—that the absolute independence and the practical irresponsibility given to our governors did facilitate the extension of our Empire (hear, hear); but nations, like individuals, prefer to manage their own affairs, and it is, on the whole, a great deal more satisfactory to know day by day and hour by hour what our agents abroad are doing, even if we do run the risk of sometimes checking and thwarting those on the spot, and interfering unwisely in local matters in deference to opinions at home. Of one thing I am sure, that the change is in the interest of peace (hear hear), and for this reason, no doubt: People on the spot when any local quarrel arises may see more clearly than we do here what is immediately before them; but they are liable to be influenced by local interests and local prejudices, and they naturally look not to the policy of the Empire as a whole, but to the policy of that small part of the Empire with which they have to do. As it affects public business there are many here who can speak to more purpose than I can; but my impression is that telegraphic communication all over the world tends to check speculation, because men act now on certain information, and not on conjecture. I think also it tends to the suppression of middlemen—to the lessening of those intermediate profits, and so, in general, to the advantage both of the producer and the consumer. That is all good as far as it goes, though no doubt it checks the growth of great commercial fortunes, and it makes business less attractive to those who have a turn for speculation. To me the chief interest in the subject lies in the absolutely new conditions of human society which telegraphs have introduced. For the first time since man existed on earth the whole human race has been brought face to face, so to speak (hear, hear, and cheers). Of course it is very hackneyed to talk about space being annihilated, but no familiarity quite takes away the feeling of wonder when one hears of men at different ends of New York, at a time when all traffic was interrupted, and the streets were blocked, and the local wires were destroyed, communicating with one another *viâ* London. That to my knowledge is a matter of fact. It is almost equally striking when one sees at the clubs the report of a battle going on somewhere in Asia or Africa, 8,000 or 10,000 miles off, and the report of that battle reaches you before the battle is concluded (cheers). Whether mankind will love one another better as they come into closer contact is an open question. I wait to see the result, but, at any rate, they will understand one another better, and that is something gained. However, I did not come here to lecture you on telegraphs or on the future of humanity. I came here to ask you, as I ask you now, to drink the health of the man to whom, more than to any other, we owe the present development of the telegraphic system of the world (cheers).

The toast was drunk with the greatest enthusiasm, the company joining in singing "For he's a jolly good fellow."

Sir JOHN PENDER, who on rising to respond was received with prolonged cheers, said: My Lord Derby, your Excellencies, my Lords and Gentlemen—Lord Derby has given to me a very pleasant task to perform, that is to present to my wife in the name of my friends a portrait of myself. I doubt whether there could be anything more pleasing for a husband to do to an affectionate and loving wife. It will afford me the greatest pleasure to make the presentation, and I believe that the pleasure she will have in receiving it from my friends may probably be the greatest she has experienced in her life (applause). Lord Derby has spoken of my early life—my early mercantile life—and of my being a self-made man. My Lords and Gentlemen, he has told you the truth and the whole truth; but when I look back to the period of my life which I spent in Lancashire, the county of which Lord Derby is so proud, and in which he is so much beloved, I may tell you that it was probably the happiest of my life. I was sowing, constantly sowing, and, I am glad to tell you, I was constantly reaping too (laughter and cheers). Probably there is nothing that affects a man more in his life than to know that when he puts his hand to anything there is a happy result to that act of his (hear, hear). I may say, I think without any hesitation, that my life in Lancashire, arduous as it was, was very happy, though very exciting. At the same time—and there are Lancashire men here, I am glad to say, who have followed my career all through—I believe that the period in which I lived in that county was probably the most remarkable in point of prosperity that it ever enjoyed. Now I pass from what I may call the first period of my life, and come to that which Lord Derby has more particularly brought before you, and which has probably more to do with the object of this gathering this evening. But when Lord Derby talks to you and to me as he has done to-night, I must say that, often as I have spoken in the interests of submarine telegraphy, I have never felt the difficulty I feel now of expressing my gratitude for the language he has used and for the reception which you have given to his remarks. It is, indeed, impossible for me to command words to express the gratitude I feel for these warm expressions of yours; but it would be altogether wrong of me were I to accept those expressions entirely to myself. I have been associated with a band of honourable and earnest men in an endeavour to accomplish a great work. We have worked hand in hand with one another, and we have, I believe, attained a great result. Why, gentlemen, it is only little more than 21 years ago since scientific men declared that submarine telegraphy was practicable. At that time a few men associated with myself took a firm grip of the question, and the result was that we carried submarine telegraphy to the position which it occupies at the present time (cheers). And what is the position it occupies at the present time? Why, this position—that there is no civilised country in the world—or there is scarcely one left out—that is not now approached by the submarine telegraph (cheers). It has brought our Indian Empire and our vast Colonial possessions into hourly touch with England. What occurs here and what occurs there are known to each alike. By submarine telegraphy war may be averted by temperate counsel promptly exercised, and due effect being instantly given to the judgment, prudence, and foresight of our statesmen. The use of the commercial capital of the world is made manifold by telegraphic communication, social intercourse is developed and widened, and the facility of our cable connection has brought us into harmony and communication with our friends beyond the seas, and in this sense it has practically created that federation which is so much desired by so many of our eminent statesmen in this country, as well as in our Colonies (cheers). In short, submarine telegraphy has brought about unity of action in all that pertains to our political, commercial, and social life. My lords

Digitized by Google

and gentlemen, I am not going to weary you with statistics, but I may submit for your reflection that the vast commerce of this Empire, as shown by our exports and imports - involving no less a sum than 1,000 millions sterling per annum—is influenced and controlled daily, as it were, by our cable communication. Yet I repeat that it is only in its early life. It is not only the commerce of this country—it is not only the capital engaged in this country—but our system is a great international system. We have created it not for ourselves alone, for there is no nation in Europe—there is no part of the civilised world—that does not receive the same benefit from submarine telegraphy that England receives, though this country has been the initiator. My Lords and Gentlemen, we have not, as has been said, girded the world to the letter—because, I may tell you, it would not pay—we have in all this great work never lost sight of the practical and commercial value that should be taken of it—but we have done more, as Lord Derby has told you. We have laid sufficient cable to girdle the world five times round (cheers), and when it becomes practicable to complete that great prophecy we are ready to do it to-morrow. All this work has cost something like 40 millions sterling, the larger portion of which—36 millions—has been subscribed by private enterprise, and only four millions by the Governments of the world. That, I say, is one of the remarkable instances where commercial enterprise has done more to benefit the world than all the Governments of the world put together. I think I may appeal to any gentleman here associated with me in the early days of telegraphy to endorse what I am about to say. I remember when we considered it a difficult question to raise £500,000 or £600,000 to lay a cable in the Atlantic, and I know very well, my lords and gentlemen, the difficulty we had in getting that sum ; but as I have already told you there are now forty millions sterling at the bottom of the sea. As Lord Derby has said, it is very difficult, having put money there, to find how to get it back, but, taking it all round, where it has been sunk it lives (cheers), and there are many whom I am addressing, and many of the public, who will agree with me when I say that we are paying a very satisfactory dividend on the money that they have invested. I may say more. A feature which I think is a very proud one indeed in regard to submarine telegraphy is that the debentures which those companies have issued hold at the present time about as high a position in the City of London as those of any other existing company. Moreover, the nations of the world are now recognising submarine telegraphy, and since I came here I have been told by one of the members of the Board of Trade that the decision of the conference which has been held for the protection of submarine telegraphs was to be confirmed by the nations represented, and that on the 1st of May we are to be recognised by the nations of the world as a great and important institution. Now that this great work is accomplished, and communication with all parts of the world made almost a certainty, who are those that most appreciate the advantages conferred by it? I will first say that statesmen—your excellencies who sit right and left of me—will recognise that submarine telegraphy has been an important advantage to you in your positions. I would say the same also of the merchants, of whom there are many here this evening ; and as to the shipowners, they all know how we have followed the flag, and how our enterprise has developed this country's commercial relations with the rest of the world (cheers). I think there are few of them who would not admit that. I will also appeal to philanthropists. They know how much human progress has been helped by this means. Our admirals and generals will, I believe, admit—and Lord Wolseley has done so this evening—that submarine telegraphy has played and will play an important part in wars, should this country unfortunately be at any time embroiled. God grant that it may be more prominent in averting than in facilitating war. I am sure Lord Wolseley and the Admirals will say Amen to that (applause). I would also appeal to the Press. I say that the power of the Press in England is felt throughout the world by this omnipotent agency (applause). Those who hold the view that the English-speaking races will eventually dominate the world, know the impulse that submarine telegraphy has given in that direction. Social life, whether as regards the classes or the masses, has been extended, and the feeling of loyalty to the Throne and attachment to the old country has been enhanced. The whole scope of good which I have briefly indicated carries its own reward to myself and those with whom I have been associated (cheers). So much for the past, or what I may call the early youth of submarine telegraphy. There are yet great questions to be solved in which submarine telegraphy is likely to play an important part. One of these is the disposal of our surplus population. We have in the past by that surplus population created colonies that are to some extent our wards. Those colonies have to be extended, and telegraphy will play an important part in doing so and sweetening and quickening emigration (applause). There is nothing probably that retards it more than the feeling of regret at leaving the old home and the old country ; but they know that through the Press they will be able to ascertain what is going on at home and all about the old surroundings, while those that are left behind will know that they will be made acquainted almost from day to day, if not from hour to hour, with what is taking place at the new homes of the emigrants. This will make our surplus population brace themselves up to leave the mother country, knowing, as I have said, that they will hear from those they leave behind, and knowing that they are going to countries where they will have elbow room and a chance in life. That consideration is of great moment at the present time to England, and of enormous importance in the future, because such emigration will create an England abroad—a people that will always be loyal to the old country (cheers). Now, let me add that the mission of submarine telegraphy is peace (hear, hear, and applause). It is beneficent in this, that its object is to advance civilisation—its object is to bring about political, commercial, and social progress. And let me say that I believe when the history of the Victorian era is written submarine telegraphy will take a very important position in its records (applause), and those friends who are associated with us—friends in England, friends in Germany, friends in America—will all have the satisfaction of knowing that they have taken part in a work which has promoted the progress of the world, and they will feel satisfied that in taking part in that work they have left the world more advanced and more in harmony than they found it (loud cheers).

The MARQUIS of TWEEDDALE: My Lords and Gentlemen, a very important toast has been entrusted to me this evening, which I am sure will receive from you a very hearty reception. The toast which I have to propose is no less a one than "Prosperity to the British Empire" (cheers). My Lords and Gentlemen, this is a toast on which much might be said, but having regard to the period of the evening at which we have now arrived you will not expect from me a long speech. I shall not dwell in dealing with it upon the marvellous extent to which our Empire has reached, embracing, as it does, one-sixth of the whole surface of the land of this world, and embracing no less a proportion of the peoples of the world. Nor will I dwell upon the energy and the enterprise which have led to the acquisition of that enormous Empire. These are matters which are familiar, or ought to be familiar, to everyone here, but I think I may be allowed to express the hope that we are not wanting in ability to maintain that Empire or in the desire to transmit it intact to those who come after us (cheers). It has often been said that it is very easy to acquire an empire, but very difficult to maintain it. History affords innumerable examples of enormous empires which have been acquired, and which have been as speedily lost; and there never was a time, I venture to think, in the history of this country when the lessons which have been thus learned were more important than they are at this moment (applause). Everyone who has paid any attention to what is going on in the world must have observed the immense interest which has been taken by foreign countries in the development of their Colonial possessions and the acquisition of new territories ; and I do not think we should be surprised if foreign nations should view, if not with envy, certainly not without some regret, the opportunities which they have lost in placing themselves in the same position as we have with respect to the world at large. This remarkable awakening on the part of foreign nations to the desirability of securing possessions and colonies throughout the world should, I think, arouse in us a desire to protect and preserve those possessions which we have acquired through the energy of those who have gone before us. Happily in this country, simultaneously with that movement which has been so marked in foreign nations, an immense change has taken place in this country in popular sentiment with respect to our position in the Colonies and our dependencies. Within the last few years a predominant school in this country advocated the principle that our Colonies should be allowed to shift for themselves without any regard to the mother country. When we talked about India the answer was, "Rather let India perish than that we should incur any great risk in its defence." I am happy to say that the school which held these views is now almost extinct (applause). On the contrary, you will see on every hand those who are advocating a very much closer alliance, a much closer connection with our Colonies and dependencies abroad than ever before in the history of this country (hear, hear). I am not going to discuss the various proposals which have been made from time to time in recent days to strengthen the ties which exist between us and our Colonies and dependencies. Some of these proposals appear to me to be very desirable, others appear to me to be rather fantastic, but in this I feel perfectly sure you will agree with me, that of all the means advanced to strengthen the ties which exist between us and our Colonies and dependencies, none have been so entirely free from any objections and so entirely advantageous to them and to us, as the establishment of that connection which has been produced by the institution of telegraphic communication between us (cheers). And when I ask you to respond to this toast, as I shall do at once, I hope you will not forget the immense share which has been taken in promoting this important and valuable enterprise by the gentleman whom we are here to honour on this occasion (applause). I think you will all reflect when you drink this toast, that no one has done so much—no statesman has done more—to establish an intimate connection with our Colonies and dependencies than the gentleman to whom I have referred (renewed cheers). I ask you now to drink to the toast of the "British Empire," connecting with it the names of two distinguished gentlemen, Sir Selwin Ibbetson, M.P., and Sir Arthur Blyth.

The toast having been duly honoured,

Sir H. SELWIN-IBBETSON, M.P., said we might well be proud of our country, considering the prominent position she had attained. England had become a great and strong nation through her commerce and the character of her people. Looking at the past history of the country, we could see how she had steadily and gradually by her commerce and enterprise spread her net over the world. That net and that spread of country was a guarantee, at all events—and a large guarantee—for the maintenance of peace, and nothing so much pointed to that conclusion as such a gathering as the present, which was to pay a tribute to the success of an Englishman—one of the type of men who had won for us our proud position (cheers). The British Empire might rest confident in her strength and in her future as long as such men remained among us to rule her destinies.

Sir ARTHUR BLYTH having also replied,

LORD ESHER proposed "The Health of the Chairman," which was drunk with great cordiality.

LORD DERBY, after acknowledging the compliment, alluded to the receipt of the following, among many other telegrams :—

ADELAIDE (from Mr. CHAS. TODD, C.M.G.).—"Australian friends add their heartiest felicitations to those tendered to Sir John Pender, K.C.M.G., at banquet to-night."

Digitized by Google

ALEXANDRIA (from Blum Pasha).—"Please receive my heartiest congratulations on the occasion of the so-well-deserved distinction conferred upon you."

ALEXANDRIA (from Nubar Pasha).—"I join all good friends united with you this evening in sincere congratulations."

ATHENS.—"Prime Minister, Miss Tricoupis, Mr. Lombardos, and all here send you their most hearty congratulations, trusting that the well-merited honour conferred upon you is only a foretaste of still higher ones."

BERLIN (from Dr. Lazard).—"Most sorry not having been able to accept kind invitation. I beg to express my full sympathy with the object of the banquet, and best wishes for Sir John Pender's future health and happiness.

BOMBAY.—"Lord Reay sends his sincere congratulations to Sir John Pender."

CAPETOWN (from Mr. James Sivewright, C.B.)—"Sincere and hearty congratulations from Capetown."

CONSTANTINOPLE (from Izzet Effendi, Director-General Ottoman Telegraphs, G. Serpos Effendi, Mr. A. de Vere and Staff).—"Constantinople begs to join her congratulations to those which are to-day offered to you by London."

COPENHAGEN (from the Chairman and Managing Director of the Great Northern Telegraph Company to Lord Derby).—"From the land in which the mighty powers of electro-magnetism first came to light, powers which were soon enrolled into the service of telegraphy, we send a warm greeting of sympathy with the banquet given in honour of Sir John Pender, K.C.M.G., through whose energy and perseverance, aided by the skill of congenial co-operators, so many of the most distant parts of the globe now enjoy instantaneous communication with each other. We trust and hope that continued cordial telegraphic relations will more and more result in benefits to the world at large."

DURBAN (from Mr. Henry Carlisle).—"Staff in South Africa respectfully tender congratulations to their Chairman."

MADRAS.—"Lord Connemara sends you cordial congratulations."

MALTA (from Mr. Robert Portelli).—"His Excellency the Governor desires me to convey to you his hearty congratulations on your well merited honours, and wishes you may live long to enjoy them."

ZANZIBAR (from the Sultan of Zanzibar).—"We congratulate you on decoration invested by Queen Victoria, hoping you will wear it happily and long."

ZANZIBAR.—"The station and 'Great Northern' united in offering warmest congratulations to Sir John Pender this evening, and hoped for long-continuance of the life he has so successfully devoted to ruling the destinies of the electric telegraph."

NEW YORK (from Mr. Norvin Green, President of the Western Union Telegraph Company, and Mr. Thos. T. Eckert, General Manager, to Lord Derby).—"Pray add our congratulations to the many which are doubtless coming from all parts of the world to Sir John Pender, on the occasion of this public recognition of his long identification with the cable enterprises which have contributed so large a share to the advancement of civilisation. We wish Sir John and Lady Pender long life and much happiness."

NEW YORK (from the President of the Dominion Telegraph Company of Canada to the Earl of Derby).—"Pray allow me to give expression to my feelings of gratification at the presentation to be made at the banquet this evening by your lordship and friends to Lady Pender, in commemoration of the honour which Her Majesty has so graciously bestowed upon Sir John Pender in recognition of his valuable public services."

NEW YORK (from Mr. E. Wiman to Lord Derby).—"As representing the telegraph systems included in the Great North-Western Telegraph Company of the Dominion of Canada, and extending all over the northern continent, permit me to tender my hearty congratulations through your lordship to Sir John and Lady Pender on the occasion which calls their friends together. Though distant from Sir John thousands of miles, nevertheless we maintain a close connection, and realise every day the vast service he has rendered the world in promoting instantaneous communication throughout its wide expanse. Kindly ask your honoured guests to accept the compliments and kind regards of our telegraphic circle."

NEW YORK (from Mr. Cyrus W. Field, to Lord Derby).—"Will your Lordship kindly convey to Sir John Pender my warmest congratulations and my regret that, living at my home in New York, I am unable to be present this evening at the banquet given to him by his many influential friends and admirers, and my consequent inability to take him by the hand and to assure him how much I appreciate his valuable services in connection with ocean telegraphy?"

NEW YORK CITY (from the Mayor to Lord Derby).—"Pray express to the assembled guests the great gratification which the American friends of Sir John and Lady Pender feel in the honours which are paid to them by their admirers, among whom please count as the most sincere Mrs. Hewitt and myself."

THE PROTECTION OF SUBMARINE CABLES.

The Board of Trade have called the attention of the Submarine Telegraph Companies of this country to a notice which appeared in Tuesday's *Gazette* relating to the International Convention for the Protection of Submarine Cables :—

NOTICE.

Submarine Telegraph Act, 1885.

(48 and 49 Vict., cap. 49.)

WHEREAS by the Submarine Telegraph Act, 1885, it is (amongst other things) enacted as follows :—

"This Act shall come into force on such day as may be fixed by a Notice in that behalf published in the *London Gazette*."

Notice is hereby given, that the day fixed for the said Act to come into force is the first day of May, 1888.

Henry G. Calcraft.
Secretary to the Board of Trade.

Board of Trade, April 20, 1888.

The full text of the Act above referred to will be found in *The Electrician*, August 7th, 1885, page 233.

DAMAGED BY LIGHTNING.

The accompanying sketch, from a photograph taken by Mr. W. Marriott of objects exhibited by the Royal College of Sur-

geons at the recent exhibition of the Royal Meteorological Society, represents a suit of clothes which were torn from the body of a labourer while standing under a tree near Ashford, Kent, during a severe thunderstorm on the 8th June, 1878. They comprise a cotton jacket, flannel under-vest, trousers, stockings, garters, boots and watch. The man was thrown some distance from the tree, while his clothes were hurled in all directions. The poor fellow was not killed, but was rendered insensible; he is still alive, and naturally has a very great dread of thunderstorms.

OBITUARY.

THOMAS RUSSELL CRAMPTON.

We regret to have to record the death of Mr. T. R. Crampton, M.Inst.C.E., which occurred at his residence in Ashley-place, Westminster, on the 19th inst. Mr. Crampton will be remembered as having successfully laid one of the first cables which connected England with France in the year 1851, a task the whole engineering responsibility of which devolved upon him. Mr. Crampton's other achievements were chiefly in the field of railway extension; but he continued to take interest in telegraphic engineering, and was at one time a member of the Council of the Society of Telegraph-Engineers and Electricians. Mr. Crampton was seventy-one years of age, having been born in 1816 at Broadstairs, Kent.

SAUNDERS' LIGHTNING GUARD.

In our issue of February 24th last we mentioned a recent instance in which a lightning flash struck the cable station at Porthcurno and fused the coils of two recorders, the only lightning protector in the station which proved efficient being one of the form devised by Mr. Wm. Saunders. Under these circumstances this form of protector is likely to come into more extended use, and the following description will therefore prove of interest:—The Saunders lightning guard consists of a brass tube, B (Fig. 1), through which passes a fine wire, W, one end of which is attached to the terminal C, and the other to a stud passing through and moving freely in the terminal C′. The spiral spring S is held in tension by the wire. The consequence is that when the fine wire is fused by lightning the spiral spring S is released, and the stud makes contact with the screw E, which with the tube is connected to earth, thereby putting the cable to "earth." The plugs A A at each end of the tube are for the purpose of bringing the line and "earth" as near together as possible. They are shown separately in Fig. 2, which also gives a transverse section of the instrument.

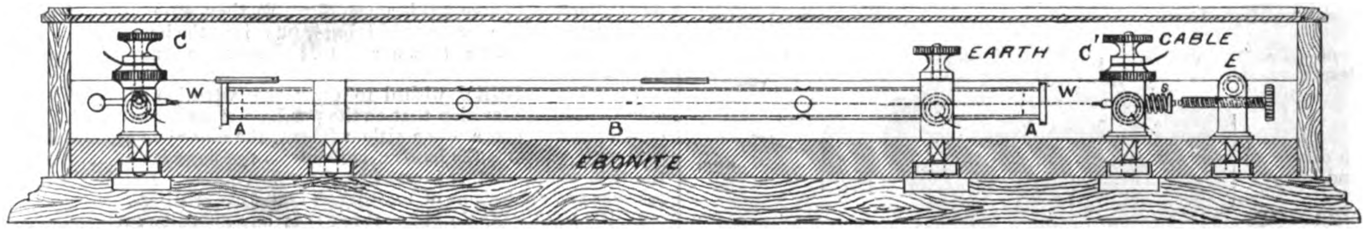

Fig. 1.—Saunders' Lightning Guard.

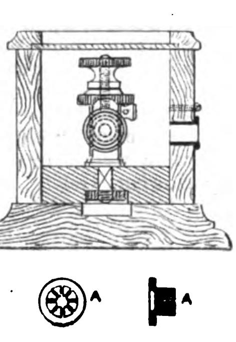

Fig. 2.

All the parts are mounted on a vulcanite base—to give good insulation between line and "earth," &c.—covered with a glass-top case.

NEW AUTOMATIC FIRE ALARM.

A new automatic fire alarm, based upon the expansion of air, is being introduced by the "Patented Appliances Company," and is shown in the adjoining cut (Fig. 1). It consists of an air chamber

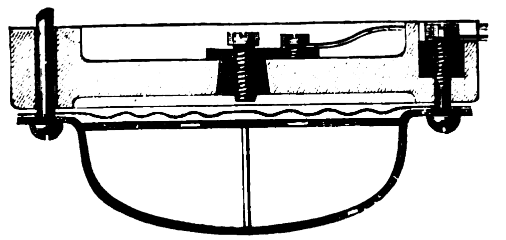

Fig. 1.

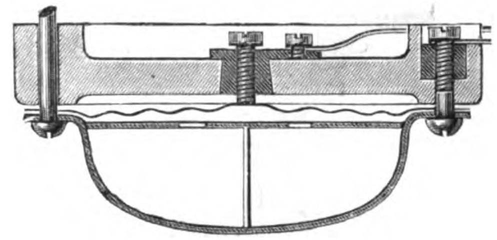

Fig. 2.

heremetically closed by a corrugated metal plate, similar to that used for an aneroid barometer. When the temperature rises to a certain point the expansion of the contained air brings the metallic plate in contact with screw, as shown in Fig. 2. This closes an electric circuit, which rings a bell, and operates an indicator in the usual manner.

NEW ACCUMULATOR AND ELECTROLIER SWITCHES.

We illustrate herewith (Fig. 1) a switch made by the Woodhouse and Rawson Electric Manufacturing Company (Limited) for enabling

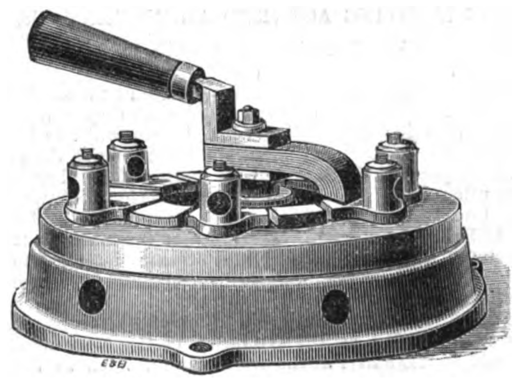

Fig. 1.

extra accumulators to be placed in or out of circuit during charge or discharge. The short-circuiting of a cell is prevented by a coil of wire of any suitable resistable mounted on a vulcanised fibre frame below the slate base, the whole switch being fixed on a hollow cast-iron frame, which is perforated in several places to allow a free current of air to pass, and it is so made that it can be

Digitized by Google

firmly screwed in any position. The brush is composed, in the usual way, of a number of independent bent plates of brass, and the instrument is well finished, while the work throughout is of the firm's usual high-class quality. These instruments are made in several sizes, according to the current required, and we understand have already been supplied, not only in England, but also to several Continental installations.

We give also illustrations (Figs. 2 and 3) of an exceedingly neat switch for use in brackets and electroliers which Messrs. Woodhouse and Rawson are now selling largely. Its arrangement is somewhat similar to their ordinary small "G" type spring break switch; it is very compact and easy to wire. The outer case has been hollowed out, so that one wire may be easily passed through,

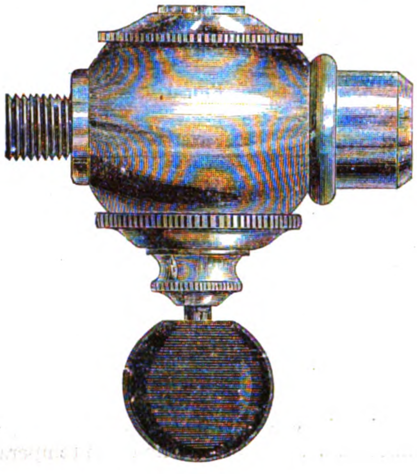

Fig. 2.

Fig. 3.

and the whole of the switch itself can be removed by unscrewing without interfering with either holder or bracket.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.—MONDAY, April 23.

ELECTRIC LIGHTING ACT (1882) AMENDMENT (No. 1) BILL.

The House went into Committee on this Bill.

On Clause 2,

The EARL OF CAMPERDOWN moved to omit the words "the goodwill of the business and of" on the ground that they rendered uncertain the elements of value in the property of the companies to be taken over. He desired at the same time that at the expiration of the period during which the companies' privileges were to endure their plant and material should be valued as being *in situ* and as suitable for the purposes for which they were intended, instead of being taken over at the "old iron" value.

The EARL OF CRAWFORD observed that inasmuch as it was understood that the noble and learned lord opposite intended to propose an amendment upon this clause, it would be convenient if he would now state the effect of that amendment.

LORD HERSCHELL said that the effect of his proposed amendment would be to insure that at the expiration of the companies' term their plant should be taken over at the price it would fetch as being ready for immediate working.

VISCOUNT BURY hoped that the word "goodwill" would not be omitted from the Bill. When the measure was before the Select Committee the Committee appeared to be divided into two parties—one in favour of giving the companies a right to the value of their goodwill, and the other in favour of treating their businesses as those of breaking-up concerns.

The EARL OF CRAWFORD said that in justice to the public they should make it clear when the companies would no longer be justified in putting fresh capital into their works for the purpose of keeping them in going order.

The MARQUIS OF SALISBURY confessed that his first view with respect to a matter of this kind was that if compulsory powers for purchase of a going concern were enacted the full value of the going concern at the time of purchase ought to be given. He did not see that there was any reason why the electric lighting companies should be burdened with burdens different from those placed upon other industries; but as he understood that the companies themselves were willing that those words should be left out, the House would be justified in agreeing to the motion. He should, however, reserve to himself the right of voting in a contrary sense on any subsequent occasion. At the same time he wished to state that he did not assent to the view either on the one hand that this industry should be subjected to greater burdens than were imposed upon others or on the other, that they were entitled to any special preference.

LORD HERSCHELL observed that he agreed with very much that the noble marquis had said. He had always thought it desirable to provide against unreasonable terms being required if the local authorities wished to purchase these undertakings; but he had never seen any reason why special burdens should be imposed upon the undertakers. If the condition were imposed upon them that at the end of any given term they should not receive the full value of the property they would recoup themselves in some other way, as by making higher charges. The present generation would thus pay more for the electric light in order that some thirty or forty years hence the next generation should have it for less than ought to pay. At the same time he recognised the difficulties of the situation, and if the Bill could not be got through without, he agreed that the word "goodwill" should be struck out of this clause. He would prefer that instead of the term "goodwill" the words "market value" should be substituted.

LORD THURLOW said he was quite willing to assent to the motion. It was essential for the passage of the Bill through another place that the word "goodwill" should not be in it. What he dreaded was that unless the purchase of these undertakings was made a fair one—and more than fair, liberal—during the last few years of the term the undertakers would be tempted to do what was called scamp the undertaking. He had consulted the representatives of most of the London and provincial electric lighting companies, and he had come to the conclusion that the prolongation of the term from 21 to 42 years, as now proposed, would be sufficient to insure the public against overcharge. On behalf of the companies he was authorised to accept this amendment, as they were satisfied that the prolongation of the term would bring capital into the business.

The amendment was then agreed to, as were some consequential amendments.

VISCOUNT BURY wished to draw the attention of the noble lord opposite to the provision that on the purchase of an undertaking the purchaser should get a clear title without the seller having to make one. This would absolve the local authority from the necessity of investigating the title to see whether it was free from mortgages He should like to ask what would become of mortgagees and other creditors.

LORD THURLOW did not think that any difficulty such as that suggested by the noble viscount would arise. At the same time he might say that he was not responsible for these words in the clause.

The clause was then agreed to.

The other clauses were also, with some amendments, agreed to, and the Bill passed through committee.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

STUDENTS' MEETING.

A students' meeting was held on Friday, April 20th, in the Society's Library, Mr. Alexander Siemens, vice-president, in the chair.

Mr. E. George Tidd read a Paper upon "The Use of Electricity for Theatre Lighting." The writer, in his opening remarks, pointed out the advantages of the light in our public places of entertainment and the practical methods of working it. He then proceeded to give a full and detailed description of the installations in our various London Theatres. The writer stated that the following ten theatres and music halls were wholly or partially lighted by electricity, viz.:—Savoy, Criterion, Gaiety, Prince of Wales, Haymarket, Terry's, Pavilion, Alhambra, Oxford, Empire, and that now it was in process of installation at the Adelphi. He considered the Criterion and the Savoy the most perfect examples, their plant having worked satisfactorily without any break or interruption, the former for over four years and the latter for seven years. Of the remainder, six have the current supplied from the Grosvenor Gallery, and the Alhambra and Pavilion have plant of their own, but only employed for lighting the auditorium. He referred to the Oxford as the most recent specimen of wiring, following the Fire Office Rules as closely as possible.

The Paper was illustrated by diagrams and by apparatus kindly lent by Messrs. E. L. Berry and Co.

A discussion followed, in which Messrs. Sanders, E. W. Smith, Dykes, Rance and Lamb took part, and after Mr. Tidd's reply, the chairman made a few remarks and the proceedings then terminated.

THE VARIATION OF THE COEFFICIENTS OF INDUCTION.*

BY W. E. SUMPNER, B.SC.

The coefficient of self-induction of a coil whose magnetic circuit is wholly or partially composed of iron is such a variable quantity that it is necessary to define its meaning more exactly than has hitherto been done. Of the many definitions possible, to give the best is probably that according to which it is the ratio of the induced electromotive force to the rate at which the current is changing. Since the induced electromotive force is equal to the rate at which the magnetism is changing, the ratio in question is the rate at which magnetism changes with the current. From this it follows that if a curve be drawn whose abscissæ represent the current, and whose ordinates represent the amount of magnetism or the number of lines of force enclosed by the coil, the coefficient for any particular current will be represented by the rate of slope of this curve. The shape of these curves is well known from the researches of Prof. Ewing, Dr. Hopkinson and others. They are generally such that as the current increases the curve slopes very gradually

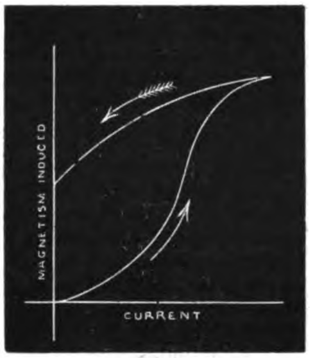

Fig. 1.

at first, but becomes steeper and steeper until the current begins to saturate the iron. The curve then bends over, and the slope becomes ultimately small. When the current is diminished the curve of magnetism, owing to magnetic hysteresis, does not return on itself, but is such that it becomes steeper and steeper as the current is diminished. Fig. 1 shows the general shape of the curve connecting the induced magnetism with the current. The arrows indicate the way in which the current is changing. Fig. 2 is a curve drawn from Fig. 1, and is such that the ordinate for any

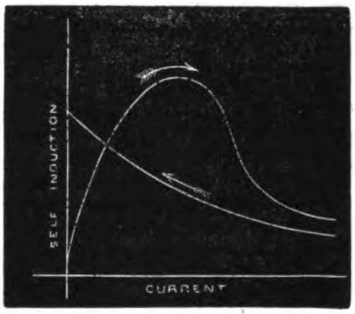

Fig. 2.

particular current represents the rate of slope of the curve in Fig. 1 for the same value of the current. The coefficient of self-induction for increasing currents at first increases and then diminishes, while for decreasing currents it is small at first and steadily increases as the current is brought to zero.

Many experiments made on an electro-magnet, on the field-magnets of dynamos, and on a Kapp transformer have completely confirmed these conclusions. Owing to magnetic hysteresis the number of lines of force enclosed by the coil will depend not only upon the current flowing at the moment, but also on those that have been flowing previously. The value of the coefficients will for the same reason depend on the former magnetising forces, and may be obtained of almost any value by using suitable magnetising currents before determining its amount. The coefficient for an increase of current will always be different from that for a decrease of current. These effects of hysteresis were obtained in all the experiments made, and were very marked in the case of a Kapp transformer. Several methods were used for determining the coefficients. The chief were Maxwell's absolute method, and a modification of it by Prof. Ayrton, a comparative method (due to the author, see *Electrician*, June 24, 1887), by which the coefficient was found in terms of the capacity of a standard condenser and the secohmeter of Profs. Ayrton and Perry.

There is a simple graphical method for determining the current flowing at any moment when the electromotive force is given at each instant, and the coefficient of self-induction is given for every value of the current. In the case of a simple circuit the following equation holds true,

$$E - L\frac{dC}{dt} = RC,$$

where C is the current, E the electromotive force (which is not necessarily constant), L the coefficient of self-induction, and t the time.

It follows that

$$\frac{dC}{dt} = \frac{\frac{E}{R} - C}{\frac{L}{R}} = \frac{C_o - C}{\frac{L}{R}}.$$

Now, $\frac{E}{R}$ is what the current would be if there were no self-induction, and is given we suppose for every moment. Call it C_o and plot a curve having C_o for ordinates and time for abscissæ. Plot another curve having current for ordinates and the corresponding value of $\frac{L}{R}$ as abscissæ. If L is given in secohms and R in ohms, L/R will be in seconds, and must be plotted to the same scale as for the former curve. It will be found best to plot the values of L/R in the negative direction, as in Fig. 3.

The construction is then as follows:—Suppose P_1 be the given

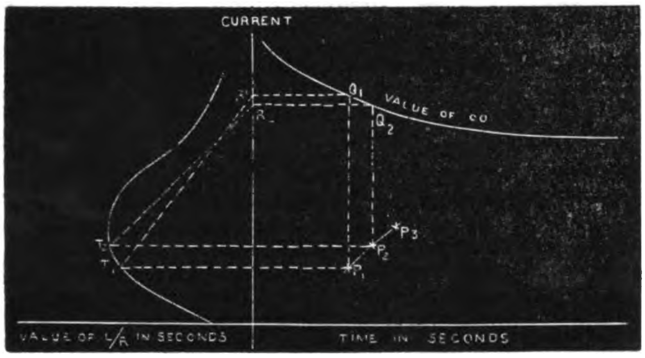

Fig. 3.

initial point on the current curve. Project it horizontally and vertically to the points T_1 and Q_1 on the curves for L/R and C_o; project the point Q_1 horizontally to R_1 on the current line. Draw from P_1 a line parallel to the line $T_1 R_1$, and choose a point, P_2, on it not far from P_1. The point P_2 may be considered as the next point on the current curve, and the process which is indicated in Fig. 3 may be repeated for the point P_2 to get a third point, P_3, and so on, until the whole curve connecting current and time is obtained.

The curves have been drawn for several cases of steady and alternating currents, and have yielded some interesting results. If the coefficient L is a variable the time taken to establish a given portion of a steady current will vary with the amount of the current to be established. The current may increase at very different rates during the rise, and may hasten and slow and hasten again while increasing in a very remarkable manner. Prof. Thompson has observed some of these effects experimentally. The general effect of the variation of L is to introduce ripples into the curve of current obtained by assuming that L is constant, and equal to the mean of the different values. It is generally assumed in calculations connected with alternating currents that the E.M.F. of the dynamo is a sine function of the time, and that the coefficient L is a constant quantity. Although these assumptions are well known to be inaccurate they are generally believed to be sufficiently true for practical purposes. It is very doubtful whether this is the case. Experiments made on the Ferranti dynamo at the Central Institution have shown that the electromotive force curve is such that its ordinates differ from those of the most favourably drawn sine curve by as much as ±5 per cent. With other dynamos probably much greater variations occur. Probably also with some dynamos the curve of electromotive force is more like that which would result from the sum of two sine curves, one with a period corresponding with the current alternations, and the other with a period coinciding with that of the

* Abstract of Paper read before the Physical Society of London, April 14, 1888.

Digitized by Google

dynamo revolutions. This will occur whenever there is want of symmetry in the machine, and this effect will be much magnified in the current curve if the self-induction is large and the alternations very rapid. That alternating currents are not generally simple sine waves seems to be indicated by the well-known pulsations to which electric lights fed with alternating currents are subject. These pulsations are too slow to be due to the ordinary current alternations, but might be in time with the revolutions of the dynamo. They are so marked in the case of one important London installation that Mr. H. B. Bourne has observed that a rapidly moving object does not present a continuous blurred appearance as if under the action of a steady light, but discontinuous images, so that, in fact, if a walking stick be swayed rapidly to and fro, the appearance is as if there were five or six instead of one only.

It does not appear to have been noticed that self-induction, although always delaying the rise or fall of currents, may sometimes hasten the discharge of a condenser. The current which discharges a condenser has both to rise and fall. The self-induction will never delay the rise so much as it delays the fall, because in the former case the potential difference of the condenser is high, while in the latter it is low. If the self-induction in the discharge circuit be not too large, the condenser will discharge quicker than if no self-induction were present, and it will always be possible to halve the time of discharge in this way. As a lightning discharge is essentially the same as that of a condenser, it seems probable that a lightning conductor will be only improved by the insertion of self-induction. Dr. Lodge has recently shown that an iron conductor is preferable to a copper one, and has accounted for it by supposing that the iron conductor has less self-induction than the copper one. It is impossible at present to say whether this is so or not, but the effect may be due to a quite opposite cause.

DISCUSSION.

Prof. PERRY considered Mr. Sumpner's Paper one of the most valuable which had recently been read before the Society. With regard to the lessening of ripples in the E.M.F. curve, or the fact that if the E.M.F. function is only approximately represented by a sine-curve, the current-function will approximate more nearly to such a curve he observed that he had found it impossible to discuss the effect except by the aid of actual numerical examples. While making some determinations of this kind with his students, he had obtained some remarkable results. As an example of the e he mentioned that when the E.M.F. curve was that due to a simple make and break contact, and therefore of the form shown at A A′ in the diagram, Fig. 4, the current function where there was great self-

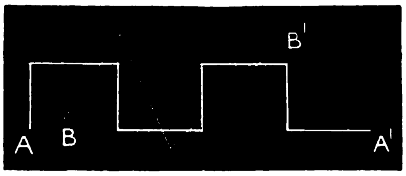

FIG. 4.

induction was represented by a curve which was not symmetrical with respect to the curve A A′, and which approximated to the form shown at B B′, when the self-induction increased definitely. It follows from those experiments that a transformer does not diminish the ripples indefinitely, but that the diminution tends towards a fixed limit.

Mr. EVERSHED observed that at the recent discussion on transformers at the Society of Telegraph-Engineers he had stated that he had arrived at a similar conclusion, and obtained a curve of the same form as Prof. Perry in the case of infinite self-induction. He had pointed out particulaly that the large ripples do not tend to disappear, but only the small ones, and also that a zig-zag E.M.F. curve does not give a current which can be even approximately represented by a sine-curve. Captain Cardew, he said, had also stated that a sine-current in the primary does not give a sine-current in the secondary. For making these statements, however, Mr. Evershed observed that he had been promptly sat upon by Prof. Perry.

In reply to Mr. Evershed Prof. PERRY pointed out that at the discussion at the Society of Telegraph-Engineers Mr. Mordey asserted that the ripples are increased by the transformer—a statement which is entirely wrong. In conclusion, Prof. Perry stated that the actual shape of the curve representing the current function had as yet not been determined experimentally in any case, and it was most important such determinations should be made.

Long-Distance Telephony in Austria.—It is stated the Austrian Telegraph Department is about to undertake the construction and working of a telephone line between Vienna and Buda-Pesth.

SYNCHRONOUS MULTIPLEX TELEGRAPHY.

[The following communication from Mr. P. Delany has been in our possession for some time, but owing to the great pressure on our space we have been unable hitherto to find room for it.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg the privilege of your columns to reply to a series of articles by Paul La Cour on "Synchronous Multiple Telegraphy," recently reprinted in the *Electrical Review* (from the *Journal* of the Franklin Institute). Several communications to the same journal from this gentleman's friends have appeared previously, but I gave them no attention. My silence has apparently lured Mr. La Cour into a repetition of the misrepresentations put forth by his friends.

If the report of the Franklin Institute had been published in England in full I would not now deem it necessary to take notice of Mr. La Cour's claims, thoroughly investigated and disposed of as they have been by that honourable body. But as only disconnected extracts have been allowed to appear in the *Review*, I am forced in the interest of truth and in justice to myself to review Mr. La Cour's latest statements.

In the first article of the series in the *Review*, September 30th, 1887, Mr. La Cour gives a history of the phonic wheel, the same as published in his pamphlet, *La Roue Phonique*, in 1878. I have always endeavoured to give Mr. La Cour full credit for the invention of the phonic wheel, and in numerous patents and printed descriptions of my synchronous system I have praised that instrument, and stated that my synchronous system was based upon it. It is with much surprise, therefore, that in the *Electrical Review* of November 4 I read a communication from a distinguished gentleman describing an instrument "nearly identical" with La Cour's, constructed by him in 1874-1875 and exhibited, with a detailed statement of the theory of its operation, at a meeting of the Physical Society on the 30th of March, 1878, and published in *Nature*, May 23rd, 1878.

It would appear from this that in reaching out for credit to which he is not entitled Mr. La Cour imperils that which silence would have secured to him.

Lord Rayleigh has not yet claimed my synchronism nor my multiplex telegraph system, although his claims would be about as valid as La Cour's.

La Cour, in proof of the success of his attempts at synchronism, refers to the tests of his system in 1880 between Fredericia and Nyborg, Denmark, a distance of forty miles, and the Danish officials of the telegraph certify to the results of the trials. The Director of Telegraphs, in his reply to the Franklin Institute inquiry, says he did not see the experiments himself, but that he is "in possession of a diary" held by an officer of the Danish Telegraphs, wherein it is stated that "during that time, from the 17th of June to the 10th of July, 1880, the phonic wheel in Fredericia and Nyborg was working every day from eight or nine in the morning to nine in the afternoon only with a few interruptions, such as disturbances on the telegraph wire or mechanical disturbances on the phonic wheel. From the period from the 22nd of June to the 10th of July it is expressly remarked that the synchronism was good." The Director further states that he is in possession of official reports which show that on the 27th of June, 1880, "were sent over one wire from 9 hours 57 minutes to 10 hours 19 minutes, simultaneously, four messages on each of the *two* circuits, from Fredericia to Nyborg, 80 words on the one and 77 words on the other circuit. From 10 hours 20 minutes to 10 hours 36 minutes, simultaneously, four messages on each of the two circuits, Nyborg to Fredericia, 68 words on one circuit and 63 on the other. From 10 hours 48 minutes to 11 hours 2 minutes, simultaneously, four messages, 65 words, from Fredericia to Nyborg."

By "simultaneously" the Director evidently means at one sending or in succession, for but two circuits were operated simultaneously.

Now, let us see what these results amount to. I cannot more clearly analyse them than by quoting from the report of the Franklin Institute Committee :—

"In the first test, lasting for twenty-one minutes, eighty words were sent on one circuit and seventy-seven on the other circuit, or an average of less than four words per minute on each circuit; or, say, eight words per minute for the whole wire. The second test gave about the same average, and the third test a slightly larger one—say, nine words per minute for the whole line.

"These experiments were made at the home of La Cour, and presumably under his supervision, and it is fair to assume that the record made was of the best performance of which the system was capable. What do the tests show? Why, most conclusively that there was no synchronism nor even an approximate synchronism. This committee is familiar with the fact that a single wire with one circuit is equal to the transmission, by the Morse system, of from forty-five to forty-eight words per minute, the limit of the ability

Digitized by Google

of expert operators to manipulate the key; and that the same wire, if duplexed, is equal to the transmission of twice as many words, and the multiplex system of Delany of six times as many words. It appears, however, that the record of the best performance of La Cour's apparatus shows but nine words per minute for both of the so-called circuits, *only one-fifth of what the wire was capable of performing as a single circuit*, or one-tenth of what it ought to have accomplished with duplex circuits. It shows that the words actually sent and received were caught by the lucky operator during the brief moments when the instruments had drifted together and before they had separated again; and it may be remarked here that the more they were out of synchronism the oftener they would drift together."

Thus, Mr. La Cour exhibits as the best performance of what he terms "perfect synchronism" during a test of twenty-three days, over a line forty miles in length, a few hours of working during which *two* circuits were operated at a speed of about four words per minute each, or nine words per minute for the entire wire. This synchronous duplex worked up to about *one-fifth* the efficiency of an ordinary simplex wire, or *one-thirtieth* of the efficiency of my present sextuplex system on a 100-mile circuit now in daily practical operation, or one-fortieth of what may be accomplished any day with my system as an octuplex on a 40-mile line.

Moses G. Farmer, of America, was probably the first to employ a single conductor for simultaneous transmission, U.S. patent 9,634, March 29th, 1853. Mr. Farmer attached to each end of a line a rapidly revolving commutator or distributor. Meyer followed with his system in 1871, and Bandot in 1874, each with revolving contact fingers for the transfer of the lines from one operator's instrument to another. Mr. La Cour will not presume to compare the results obtained by him with the operation of these synchronous systems many years before him. His perfect synchronism of 1880 was probably the most imperfect, judging from the official reports of the results that had been attempted up to that time. According to Mr. La Cour's explanation of his system, I contend that synchronism between Nyborg and Fredericia was impossible.

It is ridiculous for him to persist in asserting that he had synchronism on the occasion referred to, and with all due respect for the Danish telegraph officials, I am forced to the conviction that they were mistaken in supposing they had synchronism. Their desire for success, and commendable friendship for the effort, led them into too liberal allowances.

As I have already pointed out in my communication to the Franklin Institute, synchronism under such conditions was and is a physical impossibility.

At one station a fork made and broke automatically its own circuit through a local battery at the rate of about ninety times per second. This fork rotated a phonic wheel, the trailing arm of which made contact with numerous segments placed in the path of its rotation. With six of these segments a main battery was connected. At the distant station was placed another fork and phonic wheel. This fork was not vibrated by a local battery, but was connected to the six segments corresponding in position to the six battery-connected segments at the sending station, and was therefore to be rotated by the six impulses which came over the line at each rotation of the trailer at the first station, numbering in all about 18 per second, *provided the second phonic wheel was first in synchronism* with the first phonic wheel; otherwise the impulses coming over the line could not be delivered to the fork magnet. Therefore the fork could not vibrate, nor could the distributor revolve. With these eighteen impulses over a line the second fork was expected to vibrate in synchronism with the fork at the first station, which made for itself automatically ninety vibrations per second. Synchronism was first to be obtained by spinning the wheel by hand in order to get the fork at the second station to vibrate at all, and when once in vibration this fork, with eighteen impulses per second, coming over a line, was to vibrate synchronously with the other, and without any correcting application whatever; and yet Mr. La Cour tells us that by this method he had incessantly, from morning till night, synchronism between Fredericia and Nyborg, and the managing director of the Danish Government Telegraph has given testimony to show that this synchronism worked perfectly accurate and reliable, and was easy to manage.

Any one acquainted with the subject must see that synchronism could not be obtained in this manner. The Franklin Institute Committee is in error in supposing that the words claimed to have been transmitted were caught by the receiving operator when the instruments happened to swing together in synchronism. They could not swing apart without stopping the fork and distributor at the receiving station, since the fork could not vibrate except by the impulses received over the line, and in order to receive them the instruments *must first be in synchronism*. The circuit tables of the distributors had 60 segments; 6 of these were used for the synchronous impulses, 6 were left disconnected, and 48 were set apart for telegraphy. To start the distributors, an impetus of velocity had to be imparted to the distributor by hand. This velocity must be higher than the normal rate of notation of the first distributor. As the velocity decreased, it was expected that by chance the trailing finger would touch the six segments corresponding in position to the six battery-connected segments at the distant station exactly at the same instant that the trailing finger touched them at the first station. Should this happen, these feeble impulses at the rate of 18 per second were depended upon to keep the fork at the receiving station in absolutely synchronous vibration, and the distributor in synchronous rotation. During an experience of nearly six years with vibrators and distributors I have made many experiments to determine how long two distributors could be made to run synchronously on corresponding segments, *with each vibrator making and breaking its own circuit automatically*, and having first been balanced synchronously by means of correcting devices used in my system. By throwing off the receiving correcting switches at each distributor the instruments run independently, and as soon as a variation takes place sufficient to deliver a correcting impulse in the segment, in advance or behind the corresponding segment. At the sending station, of course, the impulses usually delivered into the correcting devices will be heard on the operator's instrument, connected to the segment adjoining the corrector segment. The time of variation from one segment to another on a sextuplex machine, with 84 segments and a like number of earth segments between, making in all 186 divisions of the circle, over which the trailer makes three complete revolutions per second, equal to the one five-hundredth part of a second for each segment, has been all the way from a few seconds to about three minutes, the average being about 20 seconds. In practice a normal balance which will keep the distributors on corresponding segments for 15 seconds is all that is ever sought before turning on the correcting switches. Now, if it be admitted, for the sake of argument, that La Cour's apparatus worked in their dependent relation as well as if they had obtained their motive power from independent sources they must, in the nature of things, have gone out of synchronism every 15 or 20 seconds, and as soon as synchronism was lost the second fork could no longer vibrate, because it was cut off from its current. In the face of these indisputable facts, easy of demonstration, Mr. La Cour and his friends in Denmark claim that synchronism was perfect from morning till night for a period covering about 20 days. During this time about one hour's work was selected as an extraordinary test, with the results claimed—two circuits, not for an hour consecutively, but intermittently, averaging four and a-half words per minute each, or, combined, about one-fifth of the capacity afforded by the same wire in the hands of expert operators without La Cour's apparatus. But I maintain that even this performance was beyond the power of the system *if the instruments were left to themselves.*

Mr. La Cour had a plan for synchronising which he has not mentioned in his contributions to scientific literature, nor in his complaints against me; and it is to this plan that I invite the special attention of scientists. It consisted of a *turntable* operated by hand, with segments and connections corresponding to and connected with the circle of segments of his distributor over which the trailing arm swept. With this turntable it might be possible to follow recreant sychronism all around the circle for a short time, and perhaps keep the fork vibrating and catch a word on the wing. I have no means of knowing whether this turntable was the secret of the synchronism claimed between Nyborg and Fredericia. Certain it is, however, that it could not have been maintained by the more theoretical plan described by Mr. La Cour. It was by the turntable plan that Mr La Cour accomplished his so-called synchronism in America in 1881. He left the turntable behind him. I will not comment on Mr. La Cour's studied avoidance of any reference to this instrument, which played such an important part in his demonstrations. I leave the scientific world to contemplate the wonderful synchronism produced by him in 1880-81, and which the Danish officials so generously endorse as "perfect synchronism."

If Mr. La Cour will pardon the suggestion, I would advise him to repeat his Fredericia and Nyborg demonstration, unless synchronism on that plan has become a lost art. Its reproduction would throw much light on this question. If he succeeds without the turntable, then I will publicly recant all my doubtings. Until he gives another demonstration, however, I shall continue to dispute the correctness of his claims, and the statements of the Danish officials as well.

The "speculators" in America, to whom Mr. La Cour refers, and to whom he had given an option, several times renewed, were his own countrymen, which is the only excuse that can be found for their statement to La Cour that "the Americans whom we had engaged, and who were supposed to be such eminent men, are possessed of considerably less theoretical knowledge than an ordinary telegraph operator in Scandinavia." It is a pity that the inability of the eminent men of America to recognise synchronism in the results officially endorsed in Denmark should have brought down upon them such a severe criticism; but I think they could better afford to concede their invincible ignorance when compared with the ordinary telegraph operator of Scandinavia rather than put

Digitized by Google

themselves on record as having obtained "perfect synchronism," whereby a multiplexed wire was reduced to one-fifth the efficiency of an ordinary single circuit, even if they had succeeded to this extent, which was not the case, Mr. La Cour having failed to provide them with a turntable, thereby giving the Scandinavians an unfair advantage. The American telegrapher needs no defence at my hands. He may not have as much theory as his Scandinavian brother; but he knows a practical telegraph system when he sees it, and it is well known that he can send more into and get more out of a telegraph wire than any other telegrapher in the world.

It seems, however, that the eminent Americans are not the only people that lacked the theoretical knowledge necessary to succeed with Mr. La Cour's apparatus. Eminent men of other countries have tried it. English, French, Germans, and Austrians have been well aware of the attempts at synchronism and the Fredericia-Nyborg demonstration, but none of them were ever able to bring about even these results. I was told by Mr. La Cour himself that he had given a half interest or more in his Austrian patents to a prominent engineer and inventor in the Austrian telegraph service, as an inducement for him to make it work and apply it to some form of telegraph. The engineer has been working at it for the past five or six years without success. The Germans purchased instruments of the La Cour type seven years ago, but have never been able to transmit one word by them. It may be that Mr. La Cour withheld the turntable, as he did from the "eminent Americans" with whom his representatives had to deal. The "speculators" before whom he demonstrated synchronism in America were evidently the kind of audience he wanted, as a turntable exploit showing the dexterity of Mr. La Cour in chasing synchronism around the circle of segments would have been more amusing than edifying to a body of electricians or telegraphists.

Mr. La Cour's patents had been allowed to lapse in every country in Europe, and had it not been for the confidence reposed in my efforts by a few American gentlemen who took up the enterprise after the Scandinavians had allowed their option to expire for the second or third time, the phonic wheel would have passed into obscurity, and its possible inventor would not now be so prominently before the public, claiming the fruits of my labour.

This, then, was the state of the art when Mr. Jones, acting for himself and others, bought Mr. La Cour's patents. Mr. La Cour must know that no American or other speculator of common intelligence, would pay a handsome sum for a telegraphic invention which, instead of being an advantage, would, according to the best showing up to that time (four words per minute by turntable), render a telegraph line worthless.

No; the patent was bought as a motor for my synchronous system, and, as such, it has been used ever since, and for this motor I have always given the inventor full credit.

Mr. La Cour had not invented his "improved synchronism" at that time. It was more than six months afterwards, Mr. La Cour says, "that a bargain was then arranged for my patent in the United States. This patent was only the patent for the phonic wheel, not for its synchronism." He had but one patent, and his "improved synchronism" was not yet invented. What, then, did Mr. Jones purchase? Simply what I required for a motor. There was no synchronism. Mr. La Cour says further, "but I undertook to inform Mr. Jones what more I had invented and possibly might invent with regard to this subject, so that he might patent in America. Mr. Jones, on the other hand, promised to send me particulars of any improvement which he might make, *so that I could patent them in Europe.*" From this it would appear that Mr. La Cour stood ready to take out patents in Europe in his own name for any improvements made in America, and because my patents were not communicated to him for this purpose he considers himself badly treated. If Mr. Jones made any such promise, he had no authority to speak for me, nor could he commit me to any such dishonest and illegal transaction.

Mr. La Cour's "improved synchronism," while a step in the right direction, and far in advance of the turntable system, was found to be impracticable then, as it is to-day, and attracted no notice here. Having received a liberal sum from the Americans for his phonic wheel, the patents for which were not worth keeping alive in Europe, and knowing that synchronism was being worked out in America, he sought to forestall us in Europe by an additional patent.

Mr. La Cour makes a baseless and misleading charge to the effect that he was lured into taking out an additional patent on his "old synchronism" in the United States in July, 1884, in the interest of Mr. Jones, so as to make it appear that his "old synchronism" was patented subsequent to the date of my patents of 1883. No one knows better than La Cour that the object of that patent was to secure better protection for his original patent in this country, and in which certain features were not fully set forth. My patents, issued nearly a year previous, all made reference to La Cour's phonic wheel.

In his second article (*Electrical Review*, October 7, 1887), Mr. La Cour gives a list of his discoveries as to how the rate of vibration of a tuning fork may be altered.

"1. By making the contacts stiffer or by approaching them to the tuning fork the number of oscillations is increased.

"2. By approaching the poles of the electro-magnet to the tuning fork the number of oscillations is reduced.

"3. By increasing the current which keeps the tuning fork in oscillation the number of oscillations is reduced.

"4. By increasing the temperature of the tuning fork the number of oscillations is reduced."

The first proposition is only partly correct. The reverse is equally true. It depends altogether where the magnet and the contacts are placed, and whether they push inwardly or outwardly. Where two contacts are used, one for each time and for running the motor and fork in separate circuits, I am strongly of the opinion that one leg of the fork may have a slightly different rate of oscillation from the other, and that the increase of pressure against one tine will affect the other, with a reverse tendency to the one directly affected. Certain it is that different amplitudes of oscillation may be produced. This will also slightly affect the synchronism, for I have found that a radical change in the strength of the motor current will affect its speed independent of the rate of the vibrator.

Regarding the second proposition, the reverse is also equally true. It depends altogether upon the *location of the magnets.* I found in 1882 that while a magnet placed outside of the tines of a vibrating fork would lower its rate of vibration. A magnet placed *within* the tines will *increase* the rate, and the stronger the current

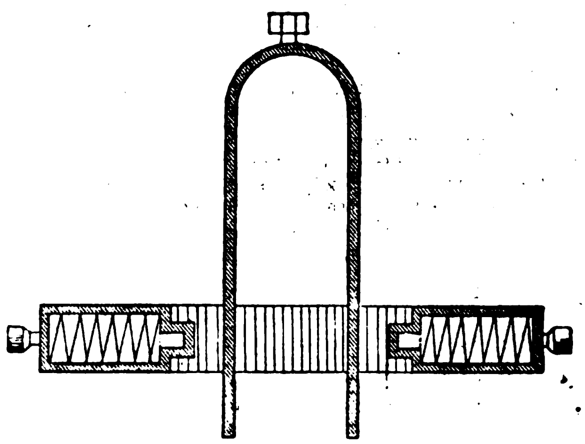

Fig. 1.

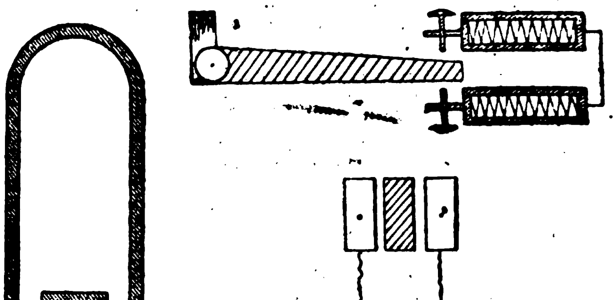
in the magnet the *higher* the rate. This also applies to the third proposition.



Figs. 2, 3, and 4.

As to the fourth, that "discovery" of Mr. La Cour's was known before he was born. Thus, without any disposition to upset Mr. La Cour's premises so far as they go it will be seen that the exact reverse of the results claimed by him are obtainable by the same identical means. In this connection I may state that a tuning fork vibrating under the influence of magnetism or in a magnetic field has a rate differing very much from its rate apart from this influence. The magnetic oscillation is not the normal rate. Tuning

Digitized by Google

forks do not answer well as automatic interrupters for synchronous movements. I failed to obtain thoroughly reliable work until I substituted reeds in 1884-5.

The claim advanced by Mr. La Cour in his writings and patents that an increase of amplitude causes a decrease in the rate is only conditionally correct, and the opposite effect is quite as readily proven. It depends upon the means used to bring about the increased or decreased amplitude of oscillation. Strengthening the current of an *actuating* magnet outside of the fork will increase the range of oscillation and lower the rate. Strengthening the current of a magnet outside the fork and independent of its vibration will *decrease* the amplitude and *lower* the rate when the magnet poles are projected towards the sides of the fork or reed. If projected towards the edges of a reed an increase of the current decreases the amplitude and *increases* the rate of oscillation. These are but a few of the peculiarities attaching to the action of vibrators discovered by me by exhaustive experiment in striving for practical results during the past six years. Still they will be sufficient to show that Mr. La Cour's discoveries are insignificant when compared with what he left undiscovered, and which he does not seem to understand even now.

If, as he says, his discoveries were published in his pamphlet in 1878, why did he not make use of them for synchronism at that time instead of waiting for Mr. Cassanges in 1886? Why did he not use these discoveries himself in America in June, 1881, three years after their publication, instead of resorting to the use of a turntable or *manual* synchronism. He should not accuse me of taking advantage of a communication to Mr. Jones in the autumn of 1882, containing what had been published to the world in 1878. He says that his discovery that varying the strength of a magnet varied the rate of a tuning fork was the main thing, that the manner of its application is of minor importance. If this be true, then his communication to Mr. Jones in 1882 and his British patent of the same year could not have been of much moment, since the broad principle was published in 1878.

The plan for synchronising proposed by Mr. La Cour in his communication to Mr. Jones was tried by Mr. Calahan and myself without any satisfactory results whatever. It has been tried in Austria without any success, so far as I am able to learn. Mr. Cassanges' experiment, according

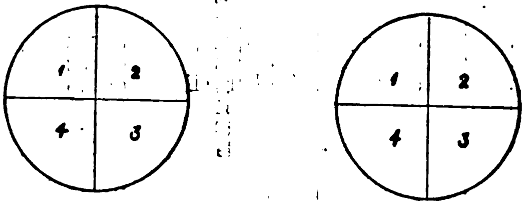


FIG. 5.

to the diagrams shown by that gentleman in a publication describing it, was *not* according to Mr. La Cour's plan. For Mr. Cassanges shows that instead of *breaking* the circuit when the armature of the polarised correcting relay moved from one stop to the other he undulated it according to my patent. If the difference is immaterial, why was my patent infringed? There is a very wide difference in this point alone. It is fully explained in my communication to the Franklin Institute:—"Reference to his description and drawings will show that the trailer H at Station 2 is expected to touch *two* contacts, *p p*, while the trailer at Station 1 is on one of the contacts, *o e*. And no matter which position the armature of the polarised relay is in, the fork and wheel *must be going either too fast or too slow*. They are not allowed to remain synchronous. Again, supposing the armature T of the polarised relay is in the position shown in the drawing, the fork is then vibrating too fast, a reverse current throws the armature over to its other stop to make it go slow, but while the armature is passing from the fast to the slow battery, the fork circuit being *entirely broken*, the rate of vibration of the fork is enormously increased, and the instruments driven away from even approximate synchronism. Therefore, when the distributor at Station 2 requires a retarding correction, it must first be accelerated far beyond the rate which called for retardation.

It must also be understood that the most delicate balance will not prevent the instruments from constant variation. If the change from the strong to the weaker battery is sufficient to *accelerate* the speed of the second instrument against its natural tendency to go slow at the time, this acceleration, being *constant*, will also be sufficient to cause the instrument to gain sufficiently in one revolution to entirely miss the segment for a retarding impulse on the next revolution, and *vice versâ*.

Assuming that a line, say, of fifty miles or upwards connects the two instruments, if a correcting impulse for slowing is needed, the trailer at Station 1 must be on battery segment *e* when the trailer at Station 2 is on the left hand contact *p*, then on account of retardation of the impulse in the line, the impulse will not arrive at Station 2 until the trailer at that station has passed off of the left-handed segment *p*, and no correction will be applied.

Again, even if it were admitted that all else worked as Mr. La Cour claims it will, it must be assumed that his correcting segments to which the batteries are connected are as broad as the other segments used for telegraph signals (for otherwise the correcting impulses would not charge the line sufficiently to be felt at the distant end). Then, this being the case, it follows that the trailer at Station 1 must be, say, half way on the battery segment before the line can be charged sufficiently to change the position of the armature of the polarised relay, and consequently the variation of the trailers would be from the middle of one segment to the middle of the other, or equal to two segments, for the spaces between the segments must be included, and each space must be equal to the width of each segment to prevent interference between the segments forming the circuits. Therefore the instruments would be out of synchronism two-thirds of the time. The charging point is indicated by the dots on the segments. Mr. La Cour makes no provision for static discharge, "tailing," or retardation of the current. The quality of all his corrections must be the same; a slight variation cannot be rectified, nor is the correction in any way proportioned to the discrepancy in synchronism. It is not necessary for me to remind your readers that synchronism at best is but a relative term; that it is all a question of degree. The Hughes, Meyer and Baudot systems are all synchronous within certain limits. Two trailers, touching corresponding sectors of these circles, might be called synchronous. But synchronism on segments one millimetre in width, in a circle five inches in diameter, with trailers revolving at the rate of three times per second, is quite a different thing.

Mr. La Cour might as well contend that there is no difference in principle between a make and break telephone and an undulating current telephone, and yet it cannot be denied that the former is of no use whatever. This particular feature constitutes but a very small part of the differences between Mr. La Cour's abortive attempts and my synchronism, covering nearly twenty patented inventions and rendering synchronism within the 1,000th part of a second a practical and constant achievement. Without this perfection multiplex telegraphy could not be accomplished.

The Cassanges experiment was made in 1886, with all my inventions before him. The reports of his experiment are made by *Mr. Cassanges himself*. His system is steno-telegraphy, one character representing a sentence, so that the number of words said to have been transmitted afford no guide as to the success or continuity of the sychronism. When Mr. La Cour told me in Berlin in 1886 that he had been witnessing Mr. Cassanges' work in Paris for two weeks, I asked him whether the three circuits claimed to have been operated were operated all in one direction or in opposite directions simultaneously. *He said he "did not know."* Synchronism, whereby three circuits are worked in one direction, using stenographic characters in the transmission of news matter, admitting of a wide range of guesswork, is at best but a slender pretext. Even this experiment involved a flagrant infringement of my patents. While in Berlin in the summer of 1886 I operated in a most successful manner for two months four circuits between Berlin and Hamburg, the circuits being worked all in one direction, or in opposite directions, or alternately in both, as the traffic demanded. Nearly all the traffic between these two cities was carried by my system during this time, and every message perfectly recorded in the Morse characters. Eight circuits for printing instruments were obtained over a similar circuit, and printers and Morse instruments were worked over the same lines at the same time. I also obtained four circuits over a sixty miles line of underground cable requiring synchronism by retarded currents, never dreamed of by Mr. La Cour.

Striving to prove that my system of reciprocal and alternating correction impulses is but an elaboration of his single impulse, Mr. La Cour draws this simile:—"If a man invents an ingenious lock and patents the same, another person has no right to patent a safe upon which he attaches two of these locks because he asserts the former inventor has only patented one lock and the greater security is obtained by two locks." But if the first man's lock is inoperative and worthless the man who invents a safe to fit and make it operative and valuable is entitled to the credit. I would not think much of a safe lock that required the inventor to hold it on the safe in order to keep the door shut. This is exactly what Mr. La Cour did with his synchronous (?) *turntable*, synchronised by turning the segments back and forth to keep up with the trailing finger.

Mr. La Cour's performance in the field of synchronism is sadly disproportionate to his claims. He appears to be another one of those inventors who waits patiently for somebody to make him famous.—Yours, &c., PATRICK B. DELANY.

84, Broad-street, New York, Dec. 24, 1887.

ON THE HEATING EFFECTS OF ELECTRIC CURRENTS.—No. III.*

pp 386, 411

BY W. H. PREECE, F.R.S.

I have taken a great deal of pains to verify the dimensions of the currents as detailed in my Paper read on December 22, 1887, required to fuse different wires in such thicknesses that the law

$$C = a\,d^{3/2}$$

is strictly followed, and I submit the following as the final values of the constant "a" for the different metals:—

	Inches.	Centimetres.	Millimetres.
Copper	10,244	2,530	80·0
Aluminium	7,585	1,873	59·2
Platinum	5,172	1,277	40·4
German Silver	5,230	1,292	40·8
Platinoid	4,750	1,173	37·1
Iron	3,148	777·4	24·6
Tin	1,642	405·5	12·8
Alloy (lead and tin 2 to 1)	1,318	325·5	10·3
Lead	1,379	340·6	10·8

With these constants I have calculated the two following tables, which I hope will be found of some use and value :—

TABLE *showing the current in amperes required to fuse wires of various sizes and materials.*

$$C = a\,d^{3/2}.$$

* Paper read before the Royal Society, Thursday, April 19th, 1888.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April 14th*, 1888.

In this country, as in England, at the present time, the subject of insurance rates, fire-office rules, &c., occupies to no small degree the thoughts of electric lighting men. In New England the general dissatisfaction at the existing state of affairs has led to the adoption of a plan which promises to introduce marked reforms. An Electric Exchange has now been organised in Boston for the object of issuing licenses to all who may be engaged in the work of electric light installation, or in wiring and general construction. The active membership in this exchange is limited to those who are actually employed in the electric lighting business in the New England States. The exchange is to have meetings four times a year, and is already organising for work, and it is to be hoped that its Board of Referees will serve as a medium of communication between members of the exchange and the various insurance authorities. It will be seen that here is the outline of a plan which might be very usefully developed all over the country, and which in its

Digitized by Google

operation would do much to raise the standard of electric light work. In the city of New York the condition of affairs is said to be satisfactory, and the enforcement of the rules laid down here has brought the loss from electric light fires very far below that from gas. But outside of the city a laxer state of affairs, it is to be feared, exists, and there seems no reason why the good results which are attained in the city should not be realised all through the State. It has been suggested that local or State bodies, in conjunction with the National Electric Light Association, might enforce a universal standard for this class of work, and thus, while preventing cheap work and reducing the amount of unholy competition, secure in the long run a greater adoption of the electric light, and generally lower rates of insurance. It may be pointed out that, as the result of the enforcement of its rules and regulations, the New England Insurance Exchange has now been able to announce a material reduction wherever the electric light is used. This is significant of other things that may be looked for from the co-operation of the insurance and electric light interests.

In my last letter reference was made to the case of Englishmen who come out here in the hope of securing positions as electricians, and who are very often disappointed in their quest. I hear of a case this week which gives point to the warning. The young fellow in question had secured a position with small salary with one of the local companies; but on certain representations was induced to make a trip from here to Montana, which is nearly equal, I believe, to the distance from England to America. When he got to his destination he found that things were not as had been stated, and that he had made a long, wearisome, and expensive journey for nothing. Of course, this threw him on his back, and as in the new Western settlements there is not a very large variety of occupations, he was only too glad to find employment as a miner. The experience in this case was a hard one, but fortunately did not have any bad effect, the man being made of sterling stuff. Still, I do not think that he received his electrical training, or made the voyage to this country, for the purpose of spending twelve hours a day as a pioneer member of the pickaxe and shovel brigade. He is now, I believe, back in New York, a good deal wiser, even if not much sadder, and it will be a long time before he is again induced to make the tour across the continent.

I would not be understood, however, to intimate that there are no opportunities here. The chances are many, and new ones crop up every day; I suppose it is simply a question of being "in the swim." For instance, not long since I predicted in this letter that with the coming of spring we would see a great revival of work in the field of electric railways. Taking up the *Electrical World* this week I find nearly forty items referring to new electric railway projects, the roads being situated in New York, Pennsylvania, Nebraska, Tennessee, Massachusetts, Ohio, Arkansas, New Jersey, Missouri, Indiana, Virginia and Illinois. A great many of these roads are already at work, either building or making the necessary changes, and it must be evident to anyone who is acquainted with the facts, that here alone is a vast amount of work to be done during the coming year. Many of these new roads will be 4 or 5 miles long, and they will illustrate all the various methods and systems in use, though the majority of them will have overhead conductors. Some idea of the interest taken in the matter may be gathered from the fact that the great Pullman Company is about to construct an electric street railway 5 or 6 miles long, double track, at Pullman, Illinois. This road will be first-class in every respect, and the mere fact of its construction by such a company indicates the way the wind is blowing.

It will be remembered that mention was made last week of the argument presented by the Edison Company before the United States Circuit Court here in regard to the limitation that is put upon American patents by foreign patents or the expiration of their "terms." The general feeling of discontent at the situation is now voiced in a Bill, which has been prepared by Mr. Arthur Steuart, the general counsel of the National Electric Light Association, and presented to Congress on behalf of that body. This Bill is intended to remove the doubts that exist on this subject, and to release American patentees from all the anxieties that have attended their movements in the endeavour to secure protection abroad as well as at home. This Bill expressly provides that "No patent granted for an invention which had prior to the grant of such patent been first patented in a foreign country, and which has not expired at the date of the passage of this Act, shall be declared to be invalid by reason of its being so limited on its face or in its grant as to expire at the same time with the foreign patent, or if there be more than one at the same time with the one having the shortest term." The Association also is urging two other Bills, one of which establishes a court of patent appeals, with a chief justice and four associates, and the other of which prolongs the term of the commissioner of patents, and increases the emoluments of himself and his associates. All these measures are regarded as being aimed in the right direction, and will enlist very general, if not unanimous, support.

By an order of the Court of Common Pleas, at Philadelphia, the celebrated Keely motor is to be inspected this month, and the results of the investigation are awaited with a great deal of interest, although it is probable they will not be made public immediately. The action of the Court in this remarkable case was brought about by a suit in which the plaintiff claims that Keely, nineteen years ago, assigned to him the patents of the wonderful motor, and the inspection now to be made by experts is for the purpose of determining whether or not the apparatus which Keely has in course of construction is the same as that alleged to have been assigned. One of the experts named by the Court is Prof. W. D. Marks, who is well known to a great many electricians from his prominent connection with the Philadelphia Electrical Exhibition in 1884, and his participation in the dynamo tests made at that time. Prof. Marks now occupies the Chair of Dynamical Engineering at the University of Pennsylvania, and is engaged also as an expert in connection with the Edison Company of Philadelphia. With him are associated men of like reputation and calibre.

From time to time we have had schemes for utilising Niagara, and some of the most recent of these I have already brought to your attention. That of the Niagara River Hydraulic Tunnel Power and Sewer Company is just now attracting public attention, and promises to be no mean enterprise. The idea of the company is to utilise some of the power of the Niagara river by boring a tunnel from the water level below the Falls, about 200ft. under the high bank of the river, extending through the rock to the upper Niagara river at a point one mile above the Falls, and at which a head of 120ft. is obtained. This tunnel is then to run parallel with the shore of the river one and a-half mile, at an average depth of 100ft. below the surface of the earth, and at a distance of about 400ft. from the navigable water of the river, with which it is to be connected by means of conduits or lateral tunnels. The point is that the power is to be obtained from the conduits, and not from the tunnel itself or from the Falls. These conduits are to have wells, in which are placed the turbines. The estimated cost of construction is £600,000, and the assertion is made that enough patronage has already been obtained to pay a fair dividend on that sum. The city of Buffalo is ready to pay £20,000 a year for power for electric lighting, and it is said that an electric smelting company is ready for the delivery of 20,000 horse-power. The company has secured land enough along the river to make room, with ample streets and dockage, for 238 mills of 500 horse-power each, or 119,000 horse-power in all, and by means of electric motors the power can, of course, be distributed over a much wider area. It is pointed out that one recommendation and beauty of the plan is that there will be no soot or smoke from the various factories, that the volume of water will not be materially lessened by the construction of the tunnel, and that the facilities for transit in all directions are admirable. The project is grandiose and typically American, and some of your readers may doubt the possibility of its execution. My own opinion is, however, that something of this kind will be done to utilise the greatest waste of water power in the world. The

Digitized by Google

success achieved at such places as Rochester in this State has done much to direct the serious attention of electricians to this subject, and whenever Niagara is utilised to any great extent it may be confidently assumed that electricity will play a leading *rôle*.

A very interesting meeting of the American Institute of Electrical Engineers was held this week, at which a Paper was read by Mr. John W. Howell, the electrician of the Edison Lamp Company, on the subject of the maximum efficiency of incandescent lamps. In using the term Mr. Howell did not mean by "maximum efficiency" the highest efficiency at which a lamp can be operated, but the efficiency at which it will give the best results considered as an element in a plant, or, in other words, the efficiency at which the cost of operating it is the minimum. Mr. Howell then submitted a number of curves in which with lamps at various costs, life, and current cost, it was shown that this efficiency was reached in every case when the lamps cost about 15 per cent. of the total expense of operating the plan. In this way, Mr. Howell established a very simple law for determining whether or not lamps are being operated at a maximum efficiency. If the lamp bills are more than 15 per cent. of the total operating expenses the lamps are being burned above their maximum efficiency. If, on the other hand, the bills are less than 15 per cent., the lamps are being burned below their maximum efficiency, and higher efficiency lamps would reduce the cost of operating the plant. From this it is deduced, for example, that where fuel is high-priced, or where other causes operate to make the cost of delivering the current high, it is imperative for economical reasons to use lamps of the maximum efficiency, the curves showing that where the cost of current is high the use of lamps a little above or below the maximum makes a very marked increase in the total operating expenses. Another important deduction was that if, for example, the lamp bills are only 10 per cent. of the total expenses, increasing the efficiency of the lamps by increasing their candle-power does not cut down the total cost; but in order to reach that desirable end the lamps must be replaced by others of the same candle power, but of higher efficiency. If, on the other hand, the efficiency of the lamps is increased by raising their candle-power, the cost of operating the plant per unit of light produced is cut down; but the total cost is increased. This law enables any one, says Mr. Howell, to determine, in the operation of an incandescent plant, whether he is using the right lamps or not. The paper, in its entirety, is a valuable contribution to the practical development of incandescent lighting, and was well received. Mr. Howell stated, in the course of the evening, that the work done on the curves extended over four or five years, involved laborious tests with hundreds and hundreds of lamps, and cost at least $10,000. The question raised in the discussion as to the effects of direct and alternating currents on the life of incandescent lamps elicited no evidence to show that the one current was more harmful or beneficial than the other. The statement was made that the uniformity of running with lamps on storage batteries had not been by any means so great as was expected, and that, practically, better results had been obtained as to steadiness of potential with currents direct from the dynamo, which gave a longer life to the lamps.

NOTES FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

PARIS, 24*th April*, 1888.

I have no change to report in electric lighting affairs. No proposition has yet been made to the city by any company, and it now seems probable that the Conseil Municipal (which assembled yesterday for a period of one month) will undertake a revision of the Cahier des Charges. In that case we may hope for such an amendment of its provisions as will render the scheme possible to undertakers for the distribution of electric light to the public. Private plants are still extending, especially in coffee houses and restaurants, in view of the approaching summer season. There was a large display of the electric light at the Military Carrousel given at the Palais de l'Industrie, Champs Elysées, on the 18th inst., for the benefit of the Société Française de Secours aux Blessés Militaires. The central part of the Palais, which occupies a space of about 600 feet long, 150 feet wide, and 120 feet high, was lighted with 60 Jablochkoff candles, 5 Gramme arc lamps of 60 amperes, 12 do. of 25 amperes, and 20 Thomson-Houston arc lights of 10 amperes. The total light amounted to about 200,000 candle-power, and the room was as well illuminated as by daylight. The *Carrousel*, given by the best cavalry squadrons from the military schools of Saumur, Saint Cyr, and Fontainebleau, was of the most brilliant effect, and attended by more than 10,000 people. M. Carnot, the President of the Republic, all the Ministers, Ambassadors, generals, &c., were present, and highly praised the electric lighting. Although the plant, under the management of M. Georges Fournier, was erected within four days, it worked most steadily and without the least trouble from 8 p.m. up to two o'clock in the morning.

Messrs. Philippart Brothers, owners of the French Faure-Sellon-Volckmar patents for the fabrication of accumulators, are instituting proceedings against MM. Gadot, Garriant and other manufacturers of accumulators. The opinions of electricians as regards the result of the suits differ widely, and some time must elapse before the final decision of the law courts is given.

CORRESPONDENCE.

TELEPHONE SYSTEMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with much interest your articles on "A Proposed Telephone System," by Mr. Walker Moseley, and although they contain valuable information, there are several points which appear to me to be open to adverse criticism.

In the first place, he describes a system of exchanges consisting of a principal one and forty other small ones. This appears to me to be a distinctly retrograde step, as it causes a multiplication of the number of exchanges, and one which is contrary to all experience. The fact that at the present time the companies in both New York and London are making every effort to cut down the number of their exchanges by centralisation would, I should think, show this to be the case.

The substance which he proposes for the insulation of wires, consisting of horsehair and resin, would appear to me to be much too brittle for this purpose; in fact, Mr. Moseley owns that it would not stand rough usage. I am inclined to doubt whether the ordinary handling in running such a wire would not break away the insulation sufficiently to admit moisture. That covering such an insulated wire with molten metal will not injure the insulating material is beyond my comprehension, and I should like to know whether this method has ever been tried even on a small scale.

His multiple switch-board is certainly exceedingly ingenious and looks well on paper, but in practice I feel that the first duty of the man who was appointed to try to keep it in working order would be to insure his life, for I am certain that it would be of but short duration. We will go into a few details about this switch-board. One of the principal desiderata of a multiple switch-board, and one which Mr. Moseley does not point out, is this—the dimensions of each section of the board should be such that an operator, when standing still, or preferably when sitting, can put a connecting plug into any plughole on that section. To do this the greatest length which can be allowed for a section is six feet, and into this length 96 plug-holes of the dimensions shown in Mr. Moseley's drawings could be fitted. By reducing the front plates of these slightly, no doubt 100 might be fitted in the six feet. Consequently, in an exchange of 3,000 subscribers there would be 30 rows of 100 plug-holes each, one row above the other in each section. Now let us try to imagine what the back of

Digitized by Google

such a board would be like. There would be 30 layers each of 100 stretched wires and chains; allowing ¾in. from wire to wire, as shown in the drawings, they will occupy a space of 6ft. 3in. by 1ft. 10½in.—that is to say, that if you stood at the back of the board, the wire nearest the board would be 6ft. 3in. away from you, and it will be well protected from any interfering persons by 99 other wires. But suppose one of these wires breaks, or even if it stretches, how is it to be got at in order that it may be repaired? And if we consider what the length of each wire in an exchange of 3,000 subscribers would be, and also the number of joints to the chains in each, it will not appear that stretching and breaking are at all unlikely events. Two hundred subscribers are generally considered as the greatest number which can be properly attended to on each section of the system of multiple switch-boards at present in use. This would give 15 sections in a 3,000 line exchange, and each section being, as I have pointed out, 6ft. long, the length of each of the wires will be 90ft., allowing no space between each section, which, however, would be necessary in practice; and the number of joints in each wire will be 32. Stretching of the wires would be easily caused by an operator pressing a plug into a plug-hole when the subscriber's line, of which that was the plug-hole, was engaged on another section; and if a wire were to stretch more than 1½in., it would prevent the indicator circuit being broken at the spring contact, shown in Fig. 12 of Mr. Moseley's drawing, when the subscriber was plugged through to another subscriber, and the result would be that their lines would be short circuited through the indicator. Another fault I should expect to be by no means unfrequent, would be the failure of this spring to make contact properly; this would happen if the wire became shortened by bending or by the chains getting twisted, both matters of possible occurrence, the result being that the subscriber would find his line insulated. There is one other matter of detail which constitutes the chief labour of fitting up, and one of the principal difficulties in the present form of multiple boards, to which Mr. Moseley does not appear to have directed his attention: it is the running of the wires for the electrical circuits. Although this appears very simple in his diagram, where the circuits of only two subscribers' lines are shown, when we remember that there will be two wires leading to and two away from each plug-hole and its back spring, making in the 3,000 line exchange 6,000 wires to and 6,000 from each section, it will easily be seen that this is a matter requiring special provision, especially with wires insulated by Mr. Moseley's method.

Finally, there is one element, viz., that of cost, which I certainly should have thought that Mr. Moseley had left out of his calculations altogether had he not stated that he will submit an estimate of the total cost of his scheme. Two appliances in his system strike me as being particularly costly, and these are his insulated copper-sheathed wire and his multiple switch-board. I shall look forward to the estimates for these with particular interest.—Yours, &c.,

London, 18th April, 1888. F. B. O. HAWES.

ALTERNATING-CURRENT TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: "An Electrical Engineer's" letter in last week's issue shows that he has not quite understood "all that has appeared in the electrical papers (including Mr. Kapp's last Paper)." If he would give the current he wishes in his secondary circuit, the size and construction of his transformer, and the number of alternations per minute he intends to use, one could answer some of his questions, since the back E.M.F. depends on all these points. As some indication of the way in which the primary current varies with that in the secondary, I may give the following figures:—In a two horse-power transformer, of the latest type, intended for 185 volts at primary and 100 at secondary, the resistance of the primary coil = ·145 ohm, that of the secondary ·042 ohm. With open circuit in the secondary the primary current was 0·8 ampere, with 15 amperes in the secondary it was 8·3, and with 30 amperes in the secondary (twice the ordinary working current) it was 16 amperes.

With regard to the advantage of the closed magnetic circuit, it is, I should think, more a question of power for a given size and cost than of efficiency. The E.M.F. that can be put on to a transformer is proportional, *cæteris paribus*, to its magnetic resistance; if instead of iron half the magnetic circuit is in air, which has a permeability only about $\frac{1}{100}$th that of iron, it is easily seen that the power of the machine is very greatly reduced.—Yours, &c.,

A STUDENT SOC. T. E. AND E.

TO THE EDITOR OF THE ELECTRICIAN

SIR: I quite agree with "Electrical Engineer's" letter in your issue of the 20th inst. A short time ago I had occasion to design an alternate-current transformer, and only then did I find the gaps which did not appear on a mere perusal of Kapp's and Dr. Fleming's Papers. Certainly Mr. Kapp's Papers on "Induction Coils Graphically Treated" go a good way towards the production of a practical instrument, but after a deal of labour one finds some formula in which two or three constants appear and no description of the right method of obtaining them. To students of the subject as it stands it now presents many difficulties, not so much electrically as mathematically. "Electrical Engineer" seems to be in much the same predicament as myself; he has gone a little way into the subject, and then meets with difficulties right and left. He speaks about the resistance which the primary coil of an A.T. must have to allow a current C to pass. If I understand aright, impedance = $\sqrt{R^2 + (2\pi n L)^2}$, so that if we know the self-induction and the number of alternations it is not such a difficult matter to calculate the current produced by a given E.M.F.

So far as my reading has gone I understand inductance = $2\pi n L$ and impedance = (ohmic res.^{2} + inductance^2) to the power ½. I think "Electrical Engineer" is down rather hard on the secondary battery, for I have a few cells for private laboratory work, and since I got them two and a-quarter years ago I have only spent one shilling on them, and that was to burn on a broken lead lug. They are discharged at varying rates, and sometimes kept running at treble the authorised discharge, and they have never given any trouble. I send them in a barrow to be charged, and with the knocking about they get I never expected to find them last any time; but there are no signs of decay at all now. There are one or two points students, I think, are generally at sea about. These are—What is the "hysteresis coefficient" of a mass of iron? What is the relation between lag of current and impressed E.M.F. and self-induction? and, last, Has an electro-magnet more or less magnetic lag with its armature off or on. I intend to perform the experiments "Electrical Engineer" spoke of when I have time, and shall give any results worth noting for his benefit. I find a commutated battery current makes a splendid alternate current.—Yours, &c., A STUDENT.

SELF-INDUCTION

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I do not know whether the report of Mr. Sumpner's Paper on the "Variation of Induction Coefficients" is intended as a full report, but there is one point in it I entirely fail to understand, viz., where he is reported to say that increase of self-induction may under certain conditions quicken the discharge of a condenser. Probably a very few words from him will suffice to explain and justify the statement, which, as it stands, is obscure.

By the way, I may as well say that I have never asserted or supposed it possible that the self-induction of an iron conductor is less than that of a copper one the same size. Its "time-constant" may be less, but that is another matter.—Yours, &c.,

OLIVER J. LODGE.

THE ROYAL VICTORIA HALL AND THE LATE MR. SAMUEL MORLEY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I ask a little of your valuable space for calling attention to a proposed memorial to one whose death was a

Digitized by Google

national loss, the late Mr. Samuel Morley? So deeply was he impressed with the dangers arising from the extremes of wealth and poverty, and the dreary lives led by the very poor, that he often spoke of society as existing on a volcano, and spared neither labour nor money to lessen the evils he deplored. Among his many useful works none was nearer to his heart than the Royal Victoria Hall, which has for its object to brighten the lives of the poor by providing healthy recreation (apart from temptations to drink) and opportunities of instruction for those who desire them. It has been carried on under many difficulties for more than seven years. Once a gift of £1,000 from Mr. Morley (towards buying the remainder of the lease) saved it in a crisis, and from that time he regularly took the chair at the committee meetings. It has occurred to those who worked with him there that there could be no more fitting memorial of his unselfish life, none more in accordance with his wishes, than to establish this work on a permanent basis. During his lifetime he caused inquiries to be made as to the possibility of buying the freehold; but the then owner refused to sell, and there appeared no prospect for the future but that the hall should relapse at the end of the ten years that the lease had still to run into the state from which the present trustees rescued it. What that state was we may learn from the pages of "Alton Locke," or from the reports of any of the police, who used often to take thirty or forty from the old theatre to the lock-up on public holidays. But an opportunity now occurs of making a return to the old horrors impossible. The ground landlord is willing to sell the freehold, and the Trustees' Committee propose to raise a memorial fund to buy it. If they succeed they have reason to think that the Charity Commissioners will take it over as part of the scheme for the proposed People's Palaces for South London. In that case there would be no more appeals to the public on its behalf; its future would be provided for, and Mr. Morley's name associated for ever with the work he did not live to finish. But the proposal is for the Commissioners to meet the public with an endowment *after* the freehold has been bought; and for this £17,000 must be raised, and raised before September, unless a deposit of £500 (already paid) is to be forfeited. The value of the freehold, we are told, is much more than this. The landlord has abated several thousands in consideration of the public utility of the object, and £4,000 is allowed for the present value of the lease, which is freely given by the trustees and committee. The £17,000 covers the remainder of the price, law expenses, &c. Towards this individuals on the committee have promised £3,500.

I will not trespass on your space with details of the entertainments, concerts, lectures, technical and other classes, working men's clubs, &c., all flourishing at the hall. Let those who wish to know come and see. The popularity of the place is shown by the fact that £1,825 was taken in nine months for admission at the doors, chiefly in sums of from a penny to threepence. I will only add that this work fitly represents Mr. Morley's generous sympathy, inasmuch as it takes no account of differences of creed or party, and that all who wish to help in perpetuating the name of a good man in the way he would have chosen are invited to communicate with Miss Emma Cons, at the Royal Victoria Hall, Waterloo-road, S.E.—Yours, &c., LUCY C. F. CAVENDISH.

4, Upper Brook-street, W., 21st April, 1888.

[*Owing to the length of the Legal Intelligence in this issue, we are compelled to leave over several Letters to the Editor.*]

COMPANIES' MEETINGS.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The twenty-ninth ordinary general meeting of this Company was held on Wednesday, at Winchester House, 50, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN stated that the gross receipts for the half year ended the 31st December last had been £232,660, being an increase, as compared with those for the same period of 1886, of £15,704; and the working expenses had been £69,570, or £10,496 less, mainly due to the cost of repairs to cables being lighter during the past half year than in 1886. The net revenue had shown an increase of £26,819, having amounted to £117,889 for the half year. For the whole year the gross receipts had been £451,861, being an increase over those of 1886 of £10,062; and the working expenses had been £145,812, being a decrease of £16,029, as compared with those for the year 1886. An interim dividend of 1¼ per cent. had been paid for the half year, and it was proposed to pay another of like amount on the following day (Thursday), making, with the interim dividends for the first half year, a total dividend of 5 per cent. It was also proposed to distribute a bonus of 3s. per share, which would make a total payment of 6½ per cent. for the past year, against 6 per cent. for the previous year. The balance of £53,051 had been carried to the general reserve fund, which now stood at £620,095. The net result of the past year's working was that the reserve fund had been increased by £50,000; the further partial renewals of the Singapore-Saigon and Penang-Rangoon cables had been paid for out of revenue, and 6½ per cent. would be distributed amongst the shareholders. Further drawings of the Company's Five per Cent. Debentures had taken place since the close of the half year, which, when paid off, would reduce the capitals outstanding as follows: Five per Cent. 1880 issue, £24,400, and Five per Cent. Australian Government Subsidy Debentures, £446,100. The completion of the renewal of Singapore-Saigon section with brass-ribboned cable had been carried out since the close of the half year. During the current year they proposed effecting some important alterations in the Madras-Penang cable, and in the Java-Australian cables. He regretted to state that they had not been successful in their negotiations with the New Zealand Government for a renewal of the subsidy, and they had, therefore, been obliged to increase the tariff over the New Zealand cable. They had thus been enabled nearly to recoup themselves for the loss of the subsidy. With reference to what had been said about a threatened Pacific cable, soundings had been ordered to be taken—a work which would occupy three years, during which period, at all events, the scheme would be in abeyance. Should the matter then arise again, they hoped the position of the Company would be so strong as to prevent the competing cable from being laid or, at least, to render its opposition devoid of annoyance or inconvenience to the Company. The Colony of West Australia was now desirous of having direct communication with the mother country; and if this desire could be acceded to in a manner which would be advantageous to the Colony and to the Company, the Directors would not lose sight of the matter. Referring to the negotiations with the Chinese Government, he stated that the agreement which had been arrived at still awaited ratification; but they themselves had no desire to hurry on the matter, for as the thing stood they retained money in their own exchequer instead of paying it away to the Chinese, who, they were quite sure, would soon see the advantage to themselves of ratifying the agreement. Since their last meeting they had completed an arrangement with the Netherlands-Indian Government for a cable of 462 miles, between Java, Baly, and Macassar, which would be paid for by that Government, and which would be a feeder to the Company's system. After referring with regret to the loss which they had sustained in the death of Sir Wm. M'Arthur, who had been connected with the Company since its formation, the Chairman concluded by moving a resolution for the adoption of the report and accounts, and the declaration of the dividend and bonus as recommended.

The Marquis of TWEEDDALE seconded the motion, which was unanimously adopted; and subsequently resolutions were unanimously passed re-electing Mr. John Denison Pender and the Marquis of Tweeddale to their seats at the Board, and reappointing the auditors, Mr. Henry Dever and Messrs. Quilter, Welton and Co.

A vote of thanks to the Chairman and Directors brought the proceedings to a close.

[We shall publish a full report of this meeting in our next issue.]

Reuter's Telegram Company (Limited).

The twenty-fourth ordinary general meeting of the shareholders was held on Wednesday, at the offices of the Company, 24, Old Jewry, Colonel James Holland, the Chairman of the Company, presiding.

The notice calling the meeting was read by Mr. F. J. GRIFFITHS, the secretary. The report and accounts were taken as read.

The CHAIRMAN said: Gentlemen, the general features of the accounts are an increase in the revenue, but a larger augmentation of expenditure, the former being £1,300 more and the latter £3,400 larger, as compared with 1886; hence the diminished dividend. The past year, though not marked by wars, yet had several prolonged periods of excitement, entailing considerable outlay, which was not compensated for by extra subscriptions, as would have been the case in the event of actual war. The totals of the balance-sheet and profit and loss account do not materially differ from the last. The sundry creditors and sundry debtors both show an increase, due to the larger transactions of the year. These have run off in the normal way, with one or two exceptions, which, however, do not involve a large amount. The reserve fund has been increased to nearly £12,000. Adverting to a question put at the last meeting the Directors think that on every favourable opportunity this fund should be continuously increased until it reaches a sum more nearly approximating to the amount of goodwill. Any writing down of the goodwill itself would appear as though the Board considered it had depreciated, whereas they hold quite a contrary opinion. The reserve fund not only serves for equalising dividends, but also gives stability to the Company. It is not deemed advisable, therefore, to fix any limit to its augmentation. In these days of competition the Company must have a good backbone to be able to meet all adverse contingencies. One such has, indeed, presented itself this

Digitized by Google

year. A section of the Australasian press has ceased to take our news, and the result is a keen competition between the seceders and those papers which continue to support the Company. We have every reason to be satisfied with the result of the struggle so far as our prestige is concerned. But wars, whether between nations or individual opponents, cost money. Without venturing to prophesy, we may fairly express the hope that the seceding papers may eventually see the futility of squandering money in the effort to compete with an organisation whose sole reason to be is to supply the Press with intelligence more cheaply, regularly, and expeditiously than is possible under separate arrangements by individual members of the Fourth Estate (cheers). These, gentlemen, are all the remarks which we deem it necessary to make. I now propose "That the report and accounts now presented be received and adopted, and entered on the minutes." Before putting the motion I shall be happy to answer any questions.

Admiral the Right Hon. Sir JOHN C. D. HAY, Bart., K.C.B., seconded the motion.

The resolution was put to the meeting, and carried unanimously.

The CHAIRMAN moved that Baron de Reuter, who retired from the Board in conformity with the Articles of Association, be re-elected a Director. Baron de Reuter, as they were aware, was the originator of the Company, and had been for a long time, and it was to be hoped would continue to be, its "guide, philosopher, and friend." The Baron was not in very strong health, and was seeking health in a milder climate; but when the weather became warmer the Directors hoped to see him back and at work again. Whenever the Board found themselves in any difficulty (which sometimes would happen in all companies) they applied to Baron Reuter, and were guided by him.

ADMIRAL Sir JOHN HAY seconded the motion, which was put and carried.

Mr. BRADSHAW said he had pleasure in moving that Messrs. Quilter, Welton and Co. be re-elected auditors, with a remuneration of 25 guineas.

Mr. FROST seconded the motion, which was put and carried.

The CHAIRMAN: Gentlemen, that concludes the business, and I have to thank you for your attendance.

Mr. MAURICE GRANT, who entered the room just as the proceedings closed, said he had one or two remarks to make, but he did not know whether he should be out of order.

The CHAIRMAN said it was not strictly according to the law of companies to enter upon any discussion when the meeting had clo ed; but if Mr. Grant wished to make any remarks he was sure the Board would be glad to listen to them.

Mr. GRANT said it was not a case of poverty with the newspapers; they were making large fortunes, and at the expense, as he thought, of this Company. The expenses of the Company were too heavy, and they were charging too little for the information which they furnished. He thought a dividend of 5 per cent. in a Company of this kind was not sufficient.

The CHAIRMAN said that every business nowadays had to contend against keen competition, and profits were cut down very considerably, and that accounted for the small return from so large an outlay. The outlay was of a very peculiar kind. The Company had to keep up a good staff; they could not go into the next street and pick up clerks who could merely write and cipher, but they required to have cultivated and intellectual men, and these they had, most of whom had been for years in the Company's employ. And if they had not men of intelligence and general knowledge they would not get on (hear, hear). The Company did not get large returns for their labour, but they did get returns. It was not from any want of endeavour on the part of the Directors that the Company did not pay more. Most of the leading papers had their own correspondents, and if the Company did not keep them supplied with information the papers would supply themselves. The cause of the profits not being larger was the keen competition. The shareholders might be sure that the Directors, who had had many years' experience in the work, did not neglect any means by which a fair return could be had for the money. He did not think any body of men could take more pains than the Directors to cut down unnecessary expenses.

Mr. GRANT said he should make it his business to see whether the Company could not pay more than that.

A SHAREHOLDER said he was a large shareholder, and had also an interest in an unfortunate newspaper, and, speaking in the latter capacity, his impression was that the Company had considerably raised their charges from time to time (a laugh).

Mr. GRANT said he had pleasure in moving a vote of thanks to the Chairman and Directors.

A SHAREHOLDER seconded the motion, which was put and carried.

The CHAIRMAN acknowledged the compliment, and added: I assure you, and I assure you with a very long experience of the matter, we have found it quite impossible up to the present time to persuade the newspapers to increase their subscriptions, and I think, sir, we shall look upon you as the best friend of the Company if you can persuade the newspapers to adopt a more liberal way (hear, hear).

The proceedings then terminated.

Western and Brazilian Telegraph Company (Limited).

The fifteenth ordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, yesterday (Thursday), under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) read the notice convening the meeting, and the minutes of the former meeting, and the report of the Directors was taken as read.

The CHAIRMAN, in the course of his opening remarks, said: The first matter I have to allude to is the retirement of our late Chairman, Sir Henry Drummond Wolff, on account of his appointment as British Minister to the Court of Persia. The vacancy created by that retirement was filled by the election of Lord Richard Browne, a gentleman of considerable experience in the management of traffic companies, which is the leading characteristic of the Company that I am speaking on behalf of to-day. My co-Directors have elected me as Chairman of the Company. We bring before you to-day, I am very pleased to observe, a state of prosperity which is unexampled in the history of the Company. You will remember that it has been our pleasing duty from time to time of late to draw your attention to the increases which have taken place in the revenues of the Company. That was not alone the case in 1885, but it was the case in 1886, and so I am glad to say it is the case in 1887. The increase in the gross revenue for the last year is no less than £21,000. In 1885 the revenue had reached £127,396, in 1886 it was £138,666, and in 1887 it has reached what I may almost term, looking at our affairs, the grand total of £159,789. Of course, an isolated increase is satisfactory, but an increase following upon other increases is still more satisfactory, because it seems to show a growing state of prosperity, arising from a continual increase of business between those countries who have these telegraphic communications. Our increase over the year 1885 amounts to upwards of 25 per cent., and our increase over 1886 to upwards of 15 per cent.; and although it does not come properly into the operations of the year now under discussion, I may tell you that at the present time the year 1888 shows a satisfactory increase over the corresponding period of 1887. That increase would have been larger but for an interruption to one of the cables, which took off a good deal of money from our line. I shall deal with that presently. The increase of revenue standing at over £21,000, it is satisfactory to observe, as the total outcome of abstracts A, B, and C, that there is only a difference of £207 increased expenditure. True, on the whole, there is a total increase of £1,712 in the expenses, but of that £1,200 is occasioned by our having had to put into the line a greater length of new cable in substitution of the old unsuitable type, whose history you are most of you well acquainted with. Therefore that is an item beyond our control, but in a sense we look upon it as a pleasing fact, because is is only the continuation, in an accidental way, of the fixed policy of this Board to improve the communications upon which, of course, the prosperity of the Company entirely depends. If you care for an analysis of those expenses I shall be very happy to give them to you. Under Abstract A there is a net increase of £2,259, of which £1,785 is in salaries and wages. Shareholders always look at these items with a considerable degree of attention, and I think they are right in doing that, because they are a constant item in the expenses, and there is a constant tendency in them to grow year by year. The Directors do their best, and I think I shall show you that we have done so in this particular case, as all through, to keep the expenses down as far as we can, and some of the expense is more nominal than real. As regards salaries and wages, the increase in that item is made up of five new clerks whom we had to send out to deal with the increased business; and that is an absolutely unavoidable expenditure if you are to do your work creditably and well, and unless you do it in that way you will not get the work. That accounts for £800. There has been a rise in exchange, but the effect of that upon the expenses is this, that we pay the men and we pay for our material the same number of milreis, but they have an enhanced value. Consequently in that £1,785 there is £537 for difference in exchange. There is a total of £1,300 of that sum, and the rest is made up of mechanical promotions of the clerks who go out under agreements, and whose salaries are subject to increase after terms of service. Therefore as you see the whole of that arises mainly from the increase of business, and it is not an avoidable expenditure. The only other item above £100 is for new instruments, £111, which is another unavoidable expenditure. Under abstract B, singular to say, there is almost the same decrease as there is increase under abstract A. Under abstract C there is only a total increase of £470. The outcome of all this is that upwards of £21,000 increased revenue has been earned at an additional outlay of just 8 per cent. And in reference to that figure I would say this, that I should very much like to get an increase of £100,000 on the same terms. The increase under certain heads of expenditure is misleading, because of the exchange. You must remember that we receive for our messages a great deal more money, and we are receiving a great deal more than we are paying away. That I may best illustrate by mentioning this fact to you, that whereas at times we have been losing on exchange up to as much as £10,000 a year and over, our loss in the past year did not exceed £1,500. Without going further into details, I may say that after crediting the reserve fund with £15,000, and after putting by £10,000 to the debenture redemption fund, we are enabled to pay you a dividend of 3 per cent., making, with the interim dividend, 4½ per cent. for the year, and to carry forward £3,464. As I began by saying, so I now end by saying, that that is the best account that we have ever presented to you, though I hope it will not be the best in the future. Certain things hang together, and they are rather big questions, namely, the debenture redemption fund, the reserve fund, and the new cables. Taking the last first, I think I have already drawn your attention to the fact that this year, owing to interruptions, though our receipts are better than for the previous year, they would have been still better by some thousands of pounds but for the interruption mentioned. We have had it seriously under consideration for some time, looking to the growth of the business of the Company, and the importance of preserving its prestige in the eyes of the public, to do something on certain sections to strengthen the system. As guiding us in the consideration of the matter, we have been thinking what it is that has built up the revenue of this concern, because it is an increasing quantity, whereas before it was a diminishing quantity. That arose from the fact that your cables were of a faulty type not calculated to do the work as it should be done, and at the very time when commerce was active, and plenty of money was to be made,

Digitized by Google

you were perhaps broken down. Here I must recognise the zeal and energy of the Managing Director, Major Wood, the Secretary, and the staff at home, and especially those in Brazil, who have all the actual work to do. What has built up this system has been the determination of the Board to place the cables in thorough working order. For that we had to take revenue and the reserves, and owing to the persistent application of these means to that purpose, we have a line that does its work extremely well. With respect to any new cables we should obtain tenders for them, in order to get them, as we should do, at the best market price of the day. With respect to raising the money for that purpose, our reserve fund would be partly appealed to, and other methods would be adopted, which the Board has been, and indeed still is, carefully considering. You will, no doubt, see that the stability of the concern will influence the price when we do call for tenders for the laying of the new cable. It is very advisable for us to continue our past policy in your interests, and strengthen the position of this concern. We thought, therefore, that we were bound, as prudent men of business, to see the amount required for the debentures at least a year or two in hand, and there is something behind that. Mr. Goschen shows by his conversion scheme that he saw that the time had arrived when securities, having a considerable time to run—at least, a good fixed permanent period, with a low interest and good security—were a very favourite investment. Our present debentures are 6 per cent.; but, fortunately for us, they are terminable debentures. They are debentures which in a couple of years we shall be drawing, and we shall be drawing them every year in increased amounts. It strikes me that an investor will scarcely care to go into the market and pay a large premium for a thing which next year, or within a year or two, may be redeemed at par; and that is a result of our policy. If we can show our undoubted strength to redeem those debentures, if we can show our financial stability with our reserves and security as an investing concern, then gentlemen may say to themselves that a debenture with a greater element of permanency, if with a smaller amount of interest, will command a better price in the market. I will now propose

"*That the report and accounts to the 31st December, 1887, be and they are hereby approved and adopted; and that, in accordance with the recommendation of the Directors, a final dividend of 3 per cent., or 9s. per share, free of income-tax, be declared for the year ended December 31st, 1887, payable on the 1st May next.*"

Mr. H. WEAVER seconded the resolution.

A short discussion followed, and in reply to questions,

The CHAIRMAN stated that the cables were now working all right from end to end. The length of the cable was 3,700 miles. They did not propose to duplicate the whole system for the present, at all events, and the necessity for doing so had not arisen. The delay in the repair of the last break was caused by the absence of their ships at the two extremities of the line, and by bad weather when the ship got on the spot. The moment the weather moderated the repairs were effected. They had at present no negotiations with the Brazilian Government. He would not say that the Directors would dismiss from their minds any idea of negotiations for the future, because it was never advisable to deprive oneself of an option. They might, by and bye, if circumstances were favourable, exercise the option of renewing the negotiations; but they might rely upon it that any course which the Directors took in connection with this matter would be in the best interests of the shareholders.

The resolution was then unanimously carried.

On the motion of Mr. C. W. EARLE, seconded by Mr. GUESDON, Mr. Andrews was re-elected a Director of the Company; and on the motion of the CHAIRMAN, seconded by Mr. GUESDON, Mr. Weaver was also re-elected to his seat at the Board. The auditor (Mr. Weise) was next re-appointed, a long and, in the result, abortive discussion following a suggestion from a shareholder as to the appointment of a second auditor—a proposal for which the Directors saw no necessity, and respecting which the opinions of the shareholders were divided.

The SECRETARY then read the notice convening the extraordinary general meeting, at which it was notified that the following resolutions would be submitted:

1. *That the 6th and 7th Articles of Association, and so much of the 26th Article of Association as includes and follows the words, "but notwithstanding any rule of law or equity to the contrary" shall be cancelled.*

2. *That Article 50 shall be modified by the insertion, after the word "yearly" of the words, "and may be held half-yearly."*

3. *That the agreement, dated 18th April, 1888, between The Western and Brazilian Telegraph Company (Limited), of the one part, and The London Platino-Brazilian Telegraph Company (Limited), of the other part, be, and the same is hereby approved and confirmed, and the Board are authorised to carry the same into effect.*

4. *That, for the purpose of the said agreement, and other the purposes of the Company, the capital of the Company shall be increased to £1,500,000 by the creation of 30,000 Shares of £15 each, to rank pari passu with the existing Ordinary Shares of the Company.*

5. *The Directors may issue the shares required, for the purposes and on the terms of the said agreement. The residue of the said shares may be issued by the Directors at such times, in such manner, and upon such terms as they determine.*

The CHAIRMAN explained with reference to the proposed modifications in the Articles of Association, that the changes would remove certain objectionable features in the present Articles, with which the present Directors had had nothing to do.

Mr. GUESDON was strongly of opinion that the proposed alterations, though in the right direction, did not go far enough. He had no objection to the issue of proxies—on the contrary; but he protested against the issue of stamped proxies.

Mr. WEAVER stated that they were not stamped now at the expense of the shareholders.

Ultimately resolutions 1 and 2 were agreed to, an alteration being made in the latter, by which it was made definite that half-yearly meetings of the Company will in future be held.

The SOLICITOR then read the proposed agreement between the Company and the London-Platino-Brazilian Telegraph Company.

The CHAIRMAN stated that by the proposed arrangement there would be a more intimate working connection between the two concerns, which would be brought under a common control with a common proprietary. The line was one continuous cable. The upshot of the arrangement was that of the £1,500,000 to which it was proposed to increase the capital of the Company, about £345,000 would go the Platino Company, supposing all that Company's shares to be exchanged, as stated in the report, and there would remain 7,090 shares unissued. After fully considering the arrangement, the Directors strongly recommended it to the shareholders. He then proposed the third resolution.

Mr. WEAVER having seconded the motion, considerable discussion ensued, Mr. GRIFFITH doubting the validity of what was proposed, and Mr. GUESDON maintaining that the terms were more favourable to the Platino Company than to the Western and Brazilian Campany, and complaining—as did another shareholder—of the proposal to compensate the Directors of the Platino Company for their loss of office.

The CHAIRMAN pointed out that the Directors of the Western Company would in future undertake for nothing the duties which had hitherto been discharged by the Board of the Platino Company.

The resolution was eventually declared carried, with 12 dissentients; and resolutions 4 and 5 were afterwards approved.

The proceedings terminated with a vote of thanks to the Chairman and Directors.

The Oriental Telephone Company (Limited).

The eighth ordinary annual general meeting of this Company was held on Wednesday at the City Terminus Hotel, Cannon-street, Mr. William Addison presiding.

The SECRETARY (Mr. Alexander B. Chalmers) having read the notice convening the meeting,

The SOLICITOR (Mr. Joseph Addison) said: Gentlemen, since the report was sent out a case has been submitted to counsel with reference to dividends which were paid in previous years. The dividend which has been mentioned in the present report is one which has been duly and fairly earned on the working for this year, but it occurred to the Directors after the notice was sent out whether anything might arise as to the payment of the dividend for the past year, and I was directed to submit a case for the opinion of counsel, whether or not the dividends which had been declared in the years 1882-3 were dividends which, as events have now turned out, could have been said to be truly and properly earned. Counsel's opinion has thrown considerable doubt upon this question, and it is only this morning that we have received that opinion, and therefore I have taken upon me the responsibility of advising the Board of Directors to this effect, that however justly they have earned the dividend during the present year, they must really carefully consider the effect of that opinion before they assume the responsibility of paying the present dividend out of the funds of the Company. I think they will do very wisely if they will first consider carefully and accurately the value of their patent rights and of their business as they now stand. It is a little unfortunate that counsel's opinion has been only just received, but the Board having fully considered the matter, think that the best thing they can do will be to ask you to allow the meeting to be adjourned for a month, when they will be prepared to lay before you their final decision, and, if thought right, recommend the dividend they had proposed to be approved to-day.

The CHAIRMAN then formally moved the adjournment of the meeting for a month.

Mr. B. ST. JOHN ACKERS: I rise, gentlemen, to second the proposition of our Chairman that this meeting do adjourn for a month. I was asked to second the suggested payment of a dividend at this meeting, and I should have far rather done that than what I am now asked to do; but I think this is so important a question, and one which touches the well-being of our Company so much, that I think it would be very unwise to come to any decision to-day. As you have heard from our legal adviser, we have every reason to believe that the dividend we were to recommend to you to-day will this day month be proposed, and, if the shareholders agree to it, declared; but until we have gone thoroughly into this question of back dividends and seen whether or not our capital has been reduced, as has been suggested, I think it would be very unwise to come to any decision. I therefore ask you to adjourn the meeting. But do not go away in the smallest degree despondent; we have had a very favourable year. We have earned quite sufficient to pay a reasonable dividend, and we have good prospects of paying you good dividends for the future. All that we ask is that we may have time to protect ourselves against doing anything that we ought not to do in the eyes of the law.

The CHAIRMAN having put the motion, it was agreed to, and the proceedings terminated.

The Maxim-Weston Electric Company (Limited).

The seventh ordinary general meeting of the above Company, which was adjourned on the 28th of March, was resumed on Wednesday last at the Cannon-street Hotel, to receive the report of the committee appointed at the first meeting to investigate and report upon the affairs of the Company. Mr. Hugh Watt, M.P., presided.

The notice convening the meeting having been read,

The CHAIRMAN called upon one of the members of the committee to read their report.

Digitized by Google

Mr. KLENCK, having briefly recapitulated the circumstances under which the committee were appointed, then read the following report:—

"(1) The committee have now to report that on going into the affairs of the Company much of their time was wasted by the obstacles put in their way when they desired access to the books and documents, and they have specially to report that up to the present time they have been unable to obtain an inspection of the minute book of the Company. (2) The committee regret to inform the shareholders that the profit shown in the balance-sheet submitted to the last meeting was misleading, and was only arrived at by the omission to make any allowance for bad or doubtful debts, and by unwarrantably writing up an increased value in the stock and patents of the Company as compared with the valuations given in the balance-sheet for 1886. The committee further state that the item in the balance-sheet for December, 1887, of 'debtors £15,001. 12s. 6d.' includes some old and some disputed accounts, the recovery of which appears to be doubtful. (3) The committee report that Mr. Louis Swaby is still a Director of the Company, and that he has held, and still holds, the necessary qualifications to retain his seat at the Board. (4) The election of Mr. George Howell, M.P., as a director of the Company was irregular, as there has not been a properly constituted Board at which he could have been elected pursuant to Clause 77 of the Company's Articles of Association since the 16th ultimo, when he became a registered holder of 250 shares of the Company. (5) The committee are strongly of opinion that under the present circumstances of the Company it is most important that the directorate should be forthwith strengthened by the addition of three, or more, independent gentlemen of resolute character and commercial experience to represent the interests of the shareholders of the Maxim-Weston Electric Company. (6) The committee approach the grave question relating to the Watt dynamo machines and the Watt arc and incandescent lamps with considerable hesitation, as they are informed by Mr. Watt that these patents are not the property of your Company, but belong to himself and others. The committee consider that steps should immediately be taken to secure the same for the Company, as they find that the energies of the officials and workmen have been mainly directed, and the plant, machinery and premises of the Company have been and are now almost exclusively used, to develop and perfect the Watt patents, and considerable amounts of the Company's money have been expended upon them. Moreover, your committee maintain that Mr. Watt's personal interest in the Watt patents can only be held in trust by him for the benefit of the shareholders of the Maxim-Weston Electric Company (Limited). (7) In concluding their report the committee venture to express their opinion that the business of the Company could be efficiently carried on at a much reduced cost.

(Signed) "J. M. KLENCK, Chairman.
"HENRY A. GREIG.
"GEO. H. HILYARD.
"JNO. MARKS.
"London, April 24, 1888." "JOHN NEWTON.

Mr. KLENCK, continuing, said that while he claimed his right to reply to any remarks which the Chairman might choose to make, at the same time he would venture to make some additional observations by way of explanation. He thought they had to thank Mr. Greig for the determined manner in which on the last occasion he moved the rejection of the report and balance-sheet, in order that an investigation of the affairs of the Company might take place. They had also to thank Mr. Dever for the qualifying letter which he added to the accounts of the Company, for if it had not been for that letter he (the speaker) was quite certain that a large number of the shareholders present at the last meeting would not have voted for the adoption of the accounts. In 1886 the patents account was £38,229, in round figures; whereas in 1887 it was written up to the extent of £40,737. That increase was made up as follows:—Cash, £44; wages at the works, £718; salaries (including Mr. Watt's experimental work) £750, and Mr. Watt's manager £200, and goods used and destroyed by experiments £325. Now came a most important item, £470 for salaries, which had been written up to patents account, as follows:—£100 to Mr. Wright, as secretary, although he (the speaker) could not understand what that gentleman had to do with the patents; £270 for office expenses, and another £100 for general office expenses, making the total he had mentioned. The stock of machinery, lamps, &c., at the factory in 1886 was £13,440. 12s. 4d., whereas in 1887 it was credited at £19,817. 7s. 6d. The plant, machinery and tools stood at £2,970. 4s. 9d. in 1886, and were written up in 1887 to £3,603. 15s. 2d.; in other words, the stock, patents and machinery, which in 1886 amounted to £54,640. 14s. 2d., were written up in 1887 to £64,158. The committee, however, failed to prove the increased value in the stock as compared with 1886, their own opinion being that a certain amount ought to have been written off instead of written up. They had not gone into any personal matters as between Mr. Swaby and Mr. Watt, not deeming those questions within their province. Mr. Brown retired from the Board on the 3rd March, and from that date (Mr. Swaby not having attended at the offices of the Company) they consequently held that all business done up to the present was done illegally, because there was not a quorum of the Board. Now he came to the most important of the whole business, and it was this, that they considered that Mr. Watt should only hold the patents of the Watt dynamo and the Watt arc and incandescent lamps in trust for the Company. Mr. Watt had used part of his salary in experiments, and written it up to patents; he had used their offices, their works, their machinery, and their wages in all his experiments, and the committee held that those patents were held, and should only be held, in trust by him for the benefit of the Company. He concluded by moving the adoption of the report.

Mr. HILYARD seconded the motion, and in the course of his remarks said that after a good deal of trouble he had discovered that the Company in 1887 turned over £7,500 in business, but to do that it had cost them £4,651. He held that there was a loss on last year's working of £2,000.

The CHAIRMAN said that after taking legal advice he found that they could do almost nothing at that meeting, because it must first be determined who the Board of Directors really were. Personally he had no animus against Mr. Swaby or anybody else. He had done the best he could for the Company. [A voice: You have done the best for yourself (laughter)]. At any rate, if that was the case, Mr. Swaby would bear a share of the onus. At the same time, he would remind them, and Mr. Swaby would agree with him. that some time ago he (the speaker), owing to other engagements, and, in fact, feeling that the business was too heavy for him, was anxious to retire from the Board, and no one more than Mr. Swaby thought that it was in the interests of the Company that he should remain, and, in fact, Mr. Swaby even pressed him to an engagement to do so. The matter was now entirely in the hands of the meeting. He had said before, and he said again, if Mr. Swaby or anybody else cared to take up the office he would willingly part with it. He held 8,000 or 9,000 shares in the company, and from first to last he had not made any money out of the concern. Even at the last meeting of the committee he had said that he was willing to forego a large portion of his remuneration to a manager who would relieve him of many of the details of the work he had done—in other words, that he was willing to pay a manager out of his own pocket. They had been placed in this position with regard to the past year, that inasmuch as dynamos which could be produced cheaper than theirs had been made in 1887, they had found it impossible to secure a great many of the contracts, which, judging from their experience of 1836, they had a right to expect. They had added to the patents account the amount stated, which he had mentioned at the last meeting. He was not there to dispute it. No doubt he had gained experience in connection with the Company, but it had not enabled him to work out the Watt system, because he told them frankly and fairly that the original plans for that system were not of his initiation. He advanced a certain amount of money for the patents on the distinct condition that the Maxim-Weston Company should benefit by them. He did not agree with the committee that the Company was virtually nothing without them. Mr. Swaby, more than Mr. Brown, wanted an arrangement made to secure them. [Mr. Swaby: I beg to deny that.] He would waive the point since Mr. Swaby dissented. He wished to be perfectly fair in his statements. There could be no doubt that the provisional arrangement come to with regard to those patents was that they could make the machines, and they had to pay a certain royalty; but if they sold nothing they had to pay nothing. Coming to the accounts, they had been prepared upon a basis, as far as he understood the matter, agreed upon between the auditors and the professional accountant who kept the books. It was a question, of course, for the shareholders to say whether their estimates were correct or not; but in a matter of that kind, he thought that they would agree with him that it was a proper subject for an expert only. It was hardly one for an ordinary business man, because they were dealing with scientific and mechanical appliances as well as commercial affairs. He affirmed and maintained that the books as kept were absolutely correct. He had five or six years' experience in connection with the Company, and that was the conclusion he arrived at. The accounts had been prepared in the same way as those of other electrical companies. If they did not wish to have the Watt patents they could lose them, and. provided the expenses were paid, they would be taken out of his hands altogether. Their chief concern in connection with the Company must necessarily be its future welfare, and the proposal that he would make in view of the committee's report was that 20 or any other number of the largest shareholders of the Company should be appointed to confer with the existing committee as to what would be best to be done in the interests of the Company, as their present uncertain position, and the recent meetings that were held, had caused them to lose business. [A Voice: What business?] The Chairman then referred to the fact that, but for those drawbacks, the Company might have been able to secure a contract for lighting from the Corporation of Bradford, involving an outlay of £10,000. It had been said that obstacles had been thrown in the way of the Committee, but the only thing that they had not received was the minute-book of the Company, and that had been withheld at the instance of Mr. Hawes, the solicitor. I am very glad to see Mr. Henderson here; he knows that under the old *régime* the contract with the Corporation was the ruin of the Company.

Mr. HENDERSON: Do not ask me to endorse what you say (cries of "Order"). I think you make random statements (interruption, and cries of "Oh, oh.").

The CHAIRMAN: It is the first time I have been told so, and I shall not address myself to you again. What I was going to say is this—that we may be greatly assisted by Mr. Howell in obtaining contracts we hope to secure from other Government departments.

After a good deal of discussion, in which Mr. Griffiths, Mr. John Newton, Mr. Henderson, Mr. Klenck, and others took part,

The CHAIRMAN moved as an amendment "That the report of the committee be not adopted."

Some further discussion having taken place,

Mr. MEREDITH moved, as an amendment, "That the committee's report be rejected."

Mr. GRIFFITHS having seconded it,

The CHAIRMAN put it to the meeting, and declared it lost. He then put the original motion, which he declared carried, with five dissentients.

The CHAIRMAN then proposed, and Mr. KLENCK seconded, "That 16 of the largest shareholders, or as many of them as will agree to act in conjunction with the present committee, be appointed as a committee to report to the shareholders as to what is best to be done in the interests of the Company, and to take an early opportunity of submitting their report to the shareholders, five to form a quorum."

The motion having been agreed to,

Mr. NEWTON proposed, and Mr. KLENCK seconded, the re-election of the auditors, and a vote of thanks to the Chairman having been passed unanimously, the proceedings terminated.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 20th, 1888, amounted to £4,104.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The coupon on this company's 5 per cent. Debentures (1880 issue) due on the 1st May proximo, will be payable on and after that date on presentation of the same at the Consolidated Bank, 52, Threadneedle-street, E.C. Coupons should be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 20th, 1888, after deducting the "fifth" of the gross receipts payable to the London-Platino-Brazilian Telegraph Company (Limited), were £3,390.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The directors of this company, owing to improvements of revenue derived from exceptional causes and some increase in the traffic, recommend a dividend of 10s. per share on account of arrears of dividend on the First Preference Shares, as compared with 6s. a year ago.

PATENT

SILICIUM BRONZE AND SILICIUM COPPER WIRE.

The best for overhead Telephone and Telegraph Lines,

AND ALL ELECTRICAL PURPOSES.

Hard Drawn High Conductivity Copper Wire.

ROLLED AND DRAWN PHOSPHOR BRONZE.

PHOSPHOR BRONZE — VULCAN — PHOSPHOR — DURO METAL

PHOSPHOR BRONZE BEARINGS, BUSHES, AND OTHER PARTS OF ELECTRICAL MACHINERY.

SOLE PROPRIETORS of the British, Indian and Colonial Patents,

THE PHOSPHOR BRONZE COMPANY (Limited),

87, Sumner Street, Southwark, London, S.E.

WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 520.—Vol. XX. FRIDAY, MAY 4, 1888. Price 4d.

NOTES.

The long and interesting speech delivered by Prof. Forbes at the last meeting of the Society of Telegraph-Engineers was received with much enthusiasm by the advocates of alternate-current distribution, who very much appreciated the scathing criticism of Mr. Crompton's figures. Prof. Forbes brings down the estimate for a 10,000-light plant on this system from £57,440 (where Mr. Crompton left it) to £34,140—a reduction of over 40 per cent. Comparing this with the battery system at £59,652, it is no wonder that the transformer men felt that the argumentative victory was practically theirs. But it seems necessary to observe—as Mr. Gordon did not fail to do—that even if Prof. Forbes's figures be accepted, his demand for overhead wires raises a practical difficulty which has still to be faced. On the other hand, we quite agree with Prof. Forbes that the conditions chosen by Mr. Crompton are not those which allow the transformer system to display its merits at the fullest advantage. For instance, we should like to know how the battery system would compare in such a case at that now actually in progress, where a large installation in the City of London is to be supplied with current from a station at Deptford.

With regard to the extremely interesting figures given by Mr. Gordon from his contract with the author of the Paper, we are at a loss to understand how the efficiency of any battery can be guaranteed to be "not less than 90 per cent." at any rate of discharge. Prof. Forbes has, moreover, proved that the Howell battery must have a still higher efficiency in order to fulfil the conditions of Mr. Crompton's Paper. What do these figures mean? Unless the Howell battery can be charged at less than 2·5 volts, or discharged at more than 2 volts per cell, there must necessarily be a loss of 20 per cent. to begin with. However, even if its efficiency be somewhat less miraculously high, it is satisfactory to hear of a battery which the makers are prepared to maintain at 12½ per cent. on the contract price.

The specimens of switches, safety fuses, &c., used by the Westinghouse Company and shown by Prof. Forbes on Thursday evening were examined with considerable interest. Upon the whole we do not think that we have much to learn from American practice with regard to the minutiæ of electric light fittings. We illustrate two of the switches in another column. The single-lamp switch has a metallic handle which is only insulated from the contact pin by a thin washer; while the design of the larger switch is simply a marvel of misplaced ingenuity.

The Earl of Onslow, in the course of the discussion referred to in our leading article this week, stated that the Post Office could not legally incur expenditure which would not either prove remunerative or be guaranteed by those deriving benefit from it. In the House of Commons the same evening this point came up indirectly on Mr. McEwan's complaint that the Postmaster-General had declined to grant a working license to the proprietors of the Writing Telegraph. His refusal has been described as part of a policy which is a check upon invention; and in a certain sense no doubt it is so; but when the nation has made up its mind to a certain policy—in this case the control of the Telegraphs by the State—it must be content to make some sacrifices, and one of these is to disallow the free competition of inventions which cannot be advantageously adopted by or adapted to the State's telegraphic system. Many ingenious inventions—and the Writing Telegraph is certainly one such—are no doubt offered to the State, and declined for the simple reason, if for no other, that the Post Office is bound to enter into no unremunerative ventures, the cost of which is not guaranteed by those who desire them to be undertaken.

We sincerely sympathise with the Rev. G. H. Staite in his endeavours to attract attention to the merits of his unfortunate father's early experiments in the field of electric lighting, although the quarter in which the claims were first set forth was not calculated to inspire the world with confidence in their genuineness. Since then the reverend gentleman has addressed himself to the more appropriate columns of *Invention*, and with all the leading facts thus brought together one cannot deny to Mr. W. E. Staite a considerable share of the merit which his son claims for him. But, on the son's own showing, this merit has been fully admitted over and over again, and, so far as we know, has not been disputed. It is very sad that a life and a considerable fortune should have been sacrificed to an enterprise which failed chiefly, perhaps, because it was premature; but such stories are only too common, and from their very nature always reach us long after the mischief has been done and is past remedy. As to Mr. Staite's prior discoveries invalidating the patents of "Mr. Edison and Dr. Siemens," the vicar of Sutton Chesney "thinks" that they may; but before acting on what he thinks we should strongly advise him to take counsel of some one more sure of electrical science than he appears to be.

THE JOHN PENDER banquet is likely to become historical, if only for the speech of Lord WOLSELEY, who made it warmer for party politics than some of its organs relished. One of them, the *Saturday Review*, although constrained to endorse all that his Lordship said, betrays its spitefulness by insinuating that the deficiencies in the next day's reports were afterwards supplied by the speaker himself. A fairer critic would have reflected that if Lord WOLSELEY had been anxious to be reported, he could have bespoke the newspaper reporters beforehand. It is not our business to defend the gallant general; but we feel it our duty to flatly contradict the insinuation above referred to, the fact being that our own report was the only one accessible to the daily papers; and this they gladly availed themselves of directly they learnt that the speech had been delivered, but certainly not at Lord WOLSELEY'S suggestion.

THE banquet itself has been the subject of much appreciative comment, the only exception, so far as we know, being that of a technical journal whose idea of submarine telegraphy appears to be that it could have got on very well without the help of money, or the discrimination and enterprise of those who possessed that commodity. Such is not at all our view, any more than it is ours that the electrical inventions which made the cables workable would have been devised if the cables had not been laid. The justice of this observation would be admitted probably by nobody more freely than the three or four eminent electricians who were unable to accept their invitations by reason of ill-health, professional engagements, or absence from the country, but whose non-appearance at the banquet has been seized with avidity in one quarter—but only one—for the purpose of depreciatory criticism.

THREE weeks have already elapsed since the commencement of the incandescent lamp patent trial, and the end is not yet in sight. Much of the evidence adduced on the part of the defendants has now been made public for the first time, and the interest of the proceedings tends to increase as the character of the defence is more fully disclosed.

ONE of the anomalies of our English Patent Law is strikingly exemplified by the constant references to a certain Mr. CHEESBOROUGH in the important trial now occupying the attention of the Courts. An outsider could scarcely fail to suppose that the aforesaid Mr. CHEESBOROUGH is a great and famous electrician; yet, so far as we are aware, Mr. CHEESBOROUGH'S title to renown rests upon no more solid basis than that of having, in his capacity of patent agent, "received a certain communication from abroad." Probably Mr. CHEESBOROUGH was as much in the dark as to the drift of this foreign intelligence as the public is as to the merits of the respective claims now being eloquently set forth in the Court of Chancery. The real claimants for the honour of having invented the so-called "flashing" process are, as most of our readers are aware, Messrs. SAWYER and MAN, of New York.

Mr. J. W. HOWELL'S Paper on the "Maximum Efficiency of Incandescent Lamps," read before the American Institute of Electrical Engineers, will be studied with great interest in this country. It contains the first published record (of a really trustworthy character) of the life of incandescent lamps, at various efficiencies. Unfortunately the results apply only to the Edison bamboo filament, a type which has almost gone out of use in this country. Since, however, it is expressly stated that the results do *not* apply to flashed filaments, we may, perhaps, hope to obtain the figures for the latter in a subsequent communication. It will be seen that the experiments have extended over a period of five years, and have involved the destruction of many hundred lamps. One word of criticism, or rather of inquiry, we venture to make. Mr. HOWELL does not tell us, as is usual in papers of this description on this side of the water, the conditions under which the experiments were carried out. What is most important is the method adopted for measuring the current and the difference of potential. A certain American electrician—though we do not for a moment suggest that Mr. HOWELL should be placed in the same category—has recently told us that the only kind of ammeter which is wanted in the States is one that a man can take to pieces and clean and re-calibrate for himself. Seeing that these experiments were commenced five years ago, it is to be hoped that the electrical measurements were not entrusted to instruments of this or, indeed, of any "commercial" type.

ACCEPTING the ascertained results, Mr. HOWELL'S experiments lead to an empirical law of a very remarkable character, which he thus formulates:—*The total cost of an installation is always a minimum when the cost of lamps is about 14·5 to 15 per cent. of the total cost of operation.* It is very difficult to understand how a law of this character can apply over any very wide range of conditions. Yet Mr. HOWELL has calculated curves for efficiencies varying from 2·38 watts per candle up to 4·32 watts per candle, for lamps costing from 25 cents to 1 dollar a piece, and for electrical energy at rates varying from 2 5 cents to 10 cents per horse-power-hour, each one of which curves shows a singularly close approximation to the law above stated. This is certainly a point which will repay more careful consideration than we are able to bestow upon it at this moment.

The development of a thoroughly practical petroleum engine capable of burning the crude oil would be an event of no small importance to the electric lighting industry, and would undoubtedly give a very great stimulus to the lighting of country houses and domestic lighting generally. The PRIESTMAN engine, which we describe in another column, seems to promise well for the fulfilment of the required conditions. Reports of a very favourable character have been made by Sir WILLIAM THOMSON, Sir SAMUEL CANNING, Mr. REDWOOD, and Messrs. ALABASTER, GATEHOUSE and Co.

THE question of a separate trade section in the London Chamber of Commerce devoting itself to the interests of electrical engineering is taken up again this month by our contemporary *Electrical Plant.* Taken up apparently to be dropped; for after a column of editorials given to its consideration, the subject is handed over to the Secretary, who

Digitized by Google

is going to write a circular letter shortly to the parties concerned; "and in their hands" *Electrical Plant* "must leave it." Just so, "there let it lay," as Lord BYRON once wrote; but whether it will hatch anything remains to be seen.

Philip Reis.—Our readers will be interested to learn that the late Emperor William of Germany, very shortly before his death, signed a decree conferring a pension of 1,000 marks per annum on the widow of Philip Reis.

Bristol.—The Dean and Chapter of Bristol Cathedral have authorised Mr. Massingham, of Taunton and Bath, to undertake the lighting of the cathedral by electricity for the forthcoming musical festival in connection with the opening of the towers.

Telephoning to Trains in Motion.—M. P. Germain has carried out some experiments upon the French railways with a view to determining the possibility of communicating with a train in motion by means of a telephone, using the two rails as conductors. His experiments seem to have met with a considerable degree of success.

Mr. Wimshurst on Influence Machines.—At the Royal Institution on Friday last Mr. James Wimshurst lectured on influence electrical machines. There was a large audience, and at the conclusion of the lecture they had the opportunity of witnessing such a display of artificial thunder lightning such as few, if any, had seen before.

Barmen: A Correction.—In a "Note" last week respecting a central lighting station carried out by Messrs. Spiecker and Co., of Cologne, the name of the place was given as Bremen instead of *Barmen*. There is a central station at Bremen also, but this has been carried out by Messrs. Siemens and Halske, in conjunction with the Edison Company.

Telegraphs in the West Indies.—News has reached the Hague that the English steamer "Roddam" has successfully laid the cable between La Guayra, in Venezuela, and Curaçao. The same telegraph vessel is now engaged in laying the cable from Willemstad to San Domingo, which places Curaçao in direct telegraphic communication with Europe.

Suez Canal.—The progress made in fitting vessels with the electric light is shown by the Consular report from Port Said. It appears that while the number of vessels passing the Suez Canal with the electric light was in January, 1887, only 13, and in February only 12, the monthly number increased steadily until in December last 73 vessels navigated the Canal with the electric light.

Lecture on the Electric Transmission of Sound.—A lecture is announced to be given at S. Matthias' Schools, Kensington, by Mr. G. W. Tunzelmann, B.Sc., on Friday, May 11, at 8 p.m. The lecturer will give a brief history of the rise and progress of telephony, and some interesting experiments will be shown, including telephonic transmission of music. The proceeds will be given to the church schools.

A Magnetic Crane.—At the Otis Iron and Steel Works, Cleveland, Ohio, an electro-magnet is employed to lift the steel ingots and other heavy masses of iron. The magnet consists of two rods of soft iron 14in. in length and 3in. in diameter, united by a cross bar of square section. It is wound with a No. 14 B. and S. gauge covered copper wire, and when excited by a current of 6 amperes it lifts a weight of 800lb. with ease.

The Lighting of the City.—At the meeting of the City Commissioners of Sewers (the City of London Lighting Authority) it was resolved that, as the application of the Gas Light and Coke Company for an opportunity to display in the City some new and improved lanterns for high-power burners was to be for an entire year, and to be carried out wholly at the expense of the gas company, the application should be complied with.

The Nordenfelt Electric Torpedo Boat. — Mr. Nordenfelt has an electric torpedo boat of an entirely novel character constructing at Messrs. Shuttleworth's works at Erith. The greatest secrecy is maintained as to the details of the vessel, but we understand (says *Iron*) that the torpedoes discharged from it will penetrate any torpedo net yet invented. This new vessel should not be confounded with the so-called "Nordenfelt submarine torpedo boat," with which it is intended to co-operate.

Mr. A. E. Kennelly.—Many of our readers will be interested in the following paragraph, which we take from a recent number of an American journal:—"At Edison's laboratory, Orange, N.J., a few evenings ago, a reception was given to the Contemporary Club, when an interesting address on electricity, especially as employed in Mr. Edison's inventions, was given by Mr. A. E. Kennelly. The guests of the evening were received and entertained by Mr. Edison and Mr. Batchelor, and were delighted with all they heard and saw."

Central Station Lighting at Earl's Court.—We understand that the House-to House Electric Light Company has taken a lease from the Metropolitan District Railway of the piece of land adjoining the West Brompton Railway Station situated between that station and the Brompton Cemetery, the area of the plot being 25,000 square feet, upon which the company proposes to lay down its first central lighting station, and to supply the district bounded by the Cromwell-road on the north, and the Fulham-road on the south.

Messrs. Saxby and Farmer.—We understand that Mr. John S. Farmer, of the firm of Saxby and Farmer, engineers, manufacturers, and telegraph-engineers and contractors, of the Railway Signal Works, Canterbury road, Kilburn, London, having acquired by effluxion of time the share and interest of Mr. John Saxby in the business, it will be carried on at the above works, as usual and as heretofore, under the style of Saxby and Farmer, and with the same management, staff, plant, patents, and appliances.

Proposed Reward for the Best Current Meter.—M. Lyon Alemand has given notice of a resolution in the Paris Municipal Council, proposing that the sum of 20,000fr. (£800) be awarded for the invention of a perfectly satisfactory current meter; the sum of 10,000fr. to be awarded as first prize, five premiums of 2,000fr. to the next best inventions. Should it be possible to use the meter with one kind of current only, continuous or alternating, then one-half of the above premiums would in that case be awarded. Finally, with a view, doubtless, of recouping themselves, the Council are to reserve the sole right to manufacture the successful meters, no royalties being paid to the inventors.

Southampton.—The Southampton Corporation at their last meeting adopted a recommendation of the Special Works Committee to light the Hartley Institution, Audit House, Guildhall, Holy Rood clock, and certain streets at Chapel by the electric light, by means of accumulators charged from dynamos worked by power obtained from the heat of the refuse destructor, sanction being given to apply for a loan of £1,440 for the purpose of carrying out the works. The annual cost of lighting of the places named by electricity is estimated at £151, whereas gas to the public institutions alone now costs £210 a year, and a total saving of £171 a year is contemplated by the new system.

Digitized by Google

New Electrodes.—We understand that M. Bandsept has devised a new method of overcoming polarisation in primary batteries. The electrodes are made of finely divided material, which is formed into plates under pressure, while being impregnated with "gassified substances" chosen according to the ulterior use to which the plate is to be put. By means of a pulveriser these "gassified substances" are projected with great force on to the material, which is compressed as it gradually becomes impregnated. The jet is straight when the electrodes are thick, and spiral or centrifugal when it is necessary to impregnate the surface only. The same process may also be applied with advantage to the construction of plates for secondary batteries.

St. Catherine's Electric Lighthouse.—The Trinity House have just completed the erection of one of the largest electric lights in the world at the St. Catherine's Lighthouse, Isle of Wight. It will be in use, we believe, on the 1st of May. The dynamos and lamps are by De Meritens, and the driving power is provided by Robey's semi-portable engines. The whole of the work has been designed and carried out under the direction of Sir James Douglass, F.R.S, who has been unremitting in his attention to all the details of the installation. The resident engineer is Mr. H. C. Millett, who for many years occupied a similar position in connection with the lighthouse at Souter Point, between Sunderland and South Shields, and who has superintended the erection of the machinery.

Victoria Hotel, Manchester.—The Victoria Hotel, one of the largest in Manchester, has just been fitted with the electric light. The installation consists of two complete plants, each capable of running 250 16 candle-power lamps. The engines are 12 h.p. (nominal), vertical type, fitted with continuous lubricators, and drive, by means of link belting, Crompton compound-wound dynamo machines, working at about 700 revolutions per minute. There are about 400 lamps distributed through the main rooms and passages, including a large underground billiard room containing ten tables, each table being lighted by six 16 candle-power lamps. The contract was placed in the hands of the Manchester Electric Supply Company (Limited), and has been carried out by Messrs. Holmes and Vaudrey, the company's engineers.

Accumulator Tests.—Prof. von Waltenhofen has recently carried out at the Electro-Technical Institute a comprehensive series of experiments with storage cells of the Fahrbaky and Schenek, Reckenzaun, and Julien type. The chief object of the experiments was to ascertain the efficiency of each type, especially for tramway purposes; and to eliminate errors in estimating the degree to which the cells had been charged or discharged the experimenter based his investigation on three measurements, viz., the electromotive force on open circuits, the density of the electrolyte, and the potential difference when at work. The efficiency of the Reckenzaun accumulator was found to be 89·3 per cent. for the quantity, and 80·85 per cent. for the energy. For the Julien accumulator, the figures were respectively 89·7 per cent. and 83·4 per cent.; whilst the Schenek-Fahrbaky accumulator gave 91 per cent. efficiency for quantity and 78·5 per cent. for energy.

King's College Engineering Society.—At a General Meeting of the King's College Engineering Society held on Tuesday, May 1st. Mr. A. H. Preece delivered his presidential address. He took for his subject the question of electric lighting from central stations, and described the following systems: (1) The direct parallel as still used in the Edison system in New York. (2) The three-wire system used by Edison in America, and patented by Dr. Hopkinson in England. (3) The direct multiple series proposed by Bernstein. (4) Distribution by means of alternate-current transformers. (5) Distribution by means of secondary batteries, as adopted by Crompton at Kensington Court. (6) Distribution by means of continuous-current transformers. He then proceeded to compare the system of transformers and that of secondary batteries, and concluded by stating the various charges to consumers made by the different electric light companies in England. After a vote of thanks had been passed to Mr. Preece the meeting adjourned.

New Method of Measuring Magnetism of Gases.—At a recent meeting of the Berlin Physical Society Prof. Helmholtz communicated the results of an investigation by Prof. Töpler, of Dresden, which he had the day before laid before the Academy of Sciences; it contains a new method for the measurement of the magnetism and diamagnetism of gases. An index drop of petroleum is placed in a glass tube bent at a very obtuse angle; on one side of the index is the gas which is to be investigated, and on the other side is atmospheric air. When placed between the poles of a powerful electro-magnet the index is moved according as the gas is more or less strongly attracted than the air; the amount of displacement is measured by a microscope. The delicacy of the method is extremely great. It was in this way observed that oxygen is most magnetic, then come air and nitric oxide; nitrogen, hydrogen, carbonic oxide, carbonic acid, gas, and nitrous oxide, on the other hand, are diamagnetic. The method employed in the above research can also be applied to the solution of various other problems, as, for instance, the determination of the pressure of small columns of gases.

Search Lights with Automatic Feed.—Search lights for naval purposes have hitherto generally been made with hand feeding gear consisting of two screws, that actuating the positive carbon having twice the pitch of the other, while the focussing was effected by a separate screw. This type of lamp is extensively used in our own navy; but as it requires one of the men to constantly watch the arc, several attempts have been made by the manufacturers of arc lamps to produce automatic feed gear for search lights. These find favour in some foreign navies, and we learn from *Industries* that Messrs. J. G. Statter and Co., of West Drayton, have now in hand for the Dutch navy four projector arc lamps, each for a current of 100 amperes, and self-feeding. The carbons are 30mm. in diameter, and the feeding mechanism is similar to that of their ordinary type of arc lamp, with hand screw for focussing the arc. Two projectors are supplied with these lamps, with Chance silvered mirrors supported in elastic brackets, so as to protect the mirrors from concussion when the guns are fired. In addition to the mirrors, the lanterns are fitted with divergers to fantail the light. The diverger when in use is put before the plate glass front, but can be swung back if a solid beam of light is required.

Formation of a Local Electric Lighting Company at Buckingham.—A public meeting to consider the advisability of forming an Electric Light Supply Company for the Borough of Buckingham was held on Wednesday evening. The Mayor presided. The hall was filled by a representative audience. Mr. Habgood read an interesting paper on "The Electric Light," and a discussion followed. The following resolutions were unanimously agreed to:—"That in the opinion of this meeting an Electric Light Power Supply Company (Limited) would be a great boon to the inhabitants of Buckingham and neighbourhood, and prove to be a great advantage and attraction to the town; that this meeting fully approves of the establishment of an Electric Light Company in Buckingham, and will use its utmost endeavours to make the same a great success." A vote of thanks

Digitized by Google

was passed to Councillor J. W. Thorpe for the way in which he had taken up the gas question in the Council. The usual vote of thanks closed the proceedings, after which the preliminary steps for the formation of the company were taken. It appears that the chief cause of the proposed establishment of the company is the excessive charge of 5s. 3d. per 1,000 for the gas.

The Influence of Light upon Electric Discharge.—MM. Wiedemann and Ebert have recently followed up the discovery of M. Hertz by examining the influence of light upon the discharge in a Geissler tube. The following are the principal results which have been obtained :—When a static machine is used the effect of light falling upon the tube from an external source is to lower the difference of potential at which the discharge can take place. When an induction coil was employed the note given by a telephone in circuit with the tube was considerably modified by the influence of light. The effect appeared, however, to depend upon the direction in which the current traversed the tube. It attains a maximum for a certain pressure of the gas; this pressure differs also with the kind of gas employed. The part of the spectrum which produces the maximum effect varies also with the nature of the gas, and for carbonic dioxide the *least* refrangible rays of the visible spectrum are the most active. The phenomenon is probably connected with the fact of the intermittent or oscillatory character of the discharge—the intermittence not being merely due to the vibrator, but to the character of the discharge itself, and perhaps of the same order as the vibrations of light.

The Royal Institution.—The annual meeting of the Royal Institution was held on Tuesday, May 1, 1888, Sir Frederick Bramwell, D.C.L., F.R.S., Honorary Secretary and Vice-President, in the chair. The annual report of the committee of visitors for the year 1887, testifying to the continued prosperity and efficient management of the institution, was read and adopted. The real and funded property now amounts to above £81,000, entirely derived from the contributions and donations of the members. Forty one new members were elected in 1887. Sixty-three lectures and nineteen evening discourses were delivered in 1887. The books and pamphlets presented in 1887 amounted to about 283 volumes, making, with 463 volumes (including periodicals bound) purchased by the managers, a total of 746 volumes added to the library in the year. Thanks were voted to the president, treasurer, and the honorary secretary, to the committees of managers and visitors, and to the professors, for their valuable services to the institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland, K.G., D.C.L., LL.D.; Treasurer, Henry Pollock, Esq.; Secretary, Sir Frederick Bramwell, D.C.L., F.R.S., M.Inst.C.E.

The "Griffin" Gas Engine.—We have received a copy of a report by Prof. A. Jamieson on the "Griffin" double-acting gas engine, which has recently been placed on the market by Messrs. Dick, Kerr and Co., of 101, Leadenhall-street. Prof. Jamieson says:—

"The engine in its general style and behaviour more closely resembles that of an ordinary double-acting steam engine than any other gas engine with which I am acquainted, for both ends of the cylinder are closed in and an impulse is given to the piston every one and a-half revolutions, *i.e.*, combustion takes place at each end of the cylinder alternately every three revolutions of the crank shaft when the engine is working under normal conditions. This feature naturally causes the speed of the gas engine to be more constant than single-acting gas engines, and therefore better adapted for driving dynamos or other machinery where constant speed is required. . . . The engine has been specially well designed with the view of transmitting the working stresses to the foundation, and thus avoiding as far as possible any annoyance from vibrations and racking. Great care has been taken to make all the working parts strong and simple, while the workmanship and finish throughout seem to me all that could be desired. . . . The efficiency $\left(i.e. \frac{\text{brake horse-power}}{\text{indicated horse-power}}\right)$ amounted to 78·7 per cent."

Judging from this report, it would appear that the "Griffin" engine is likely to achieve a considerable success.

Lighthouse Communication.—In the House of Lords on Friday last the Earl of Morley called attention to the report of the committee appointed by the Board of Trade to inquire into the desirability of electrical communication between light vessels and outlying lighthouses and the shore. Signalling by means of rockets or guns was unsatisfactory, inasmuch as rockets could not always be seen and guns could not always be heard. In the substitution of telegraphy we should not be behind other countries if it could be proved that a change of system would conduce to the saving of life at sea.—The Earl of Onslow pointed out that it would be quite impossible to apply any portion of the mercantile marine fund towards the establishment of communication between lightships and lighthouses and the shore. If anything was done in this direction in the interests of commerce it must be done by the shipowners or by the Post Office, although the Post Office were bound by Treasury regulations to incur no expenditure which would not be remunerative, or the interest of which was not guaranteed by those deriving the benefit. Apart from the question of cost, the risk to the ships themselves by introducing telegraphic connection with the shore must be considered. At present most of the lightships were approached by about six other vessels a day; but if it became known that electrical communication could be had with the shore, the number would, no doubt, soon increase to twenty or more a day. The danger would then arise of the running down of the lightships themselves, thereby leaving dangerous shores without warning to mariners. Experiments were being made by Lloyd's with a view to the establishment of improved communication between these vessels and lighthouses and the shore without any direct metallic contact.

Licenses for Electricians in New England.—The electricians of New England have taken an important step in forming an "Electric Exchange." The object of the exchange is stated by the rules to be the "general promotion of electrical business, and especially in the direction of securing perfection in electric light and electric power installations, and in harmonising and adjusting, as far as possible, all differences which may arise between various electrical interests;" but more interesting and important is the determination to issue licenses to electricians. There are five classes of licenses:—(1) To persons qualified to install and operate arc, incandescent, or power plants; (2 and 3) To persons qualified to install and operate any two or one, respectively, of the foregoing; (4) To persons competent to operate electric machinery; (5) To persons competent to do electric wiring. Before obtaining a license (of any class) candidates must pass an examination set by three examiners selected by the committee of the exchange. On satisfying the examiners, a license bearing the seal of the exchange and signed by an officer of the Boston Tariff Association, or the New England Insurance Exchange, will be issued. Licenses are renewable annually, and even a holder of a first-class license may be called upon to undergo further examination in order to show that his knowledge is

Digitized by Google

keeping pace with the march of electrical science. The appearance of the insurance associations in the matter is explained by the facts that the exchange has for one of its objects to act as an intermediary between the electricians and the insurers, and that the latter have agreed to reduce their rates for buildings fitted by licensees of the former. The exchange invites "everyone actually engaged in manufacturing or installing electric light or electric-power apparatus, or in operating commercially an electric light or power plant" to become members.

Anniversary Celebrations by Spanish Telegraphists.—The 22nd of April last was the thirty-third anniversary of the inauguration of the first telegraph line in Spain. The event was celebrated by banquets in most of the important centres, Madrid alone being conspicuous, according to a local paper, for the absence of any commemoration. In Barcelona a banquet was held in the Hotel Miramar, under the presidency of Señor Savall, the chief officer of the telegraph service in that district. Señor Savall expressed his regret that the financial position of the department did not permit of a more liberal acknowledgment of the services of the subordinate officers. Señor Saavedra gave an interesting historical survey of the telegraph in Spain, and he was followed by Mr. Browne, the representative in Barcelona of the Direct Spanish Telegraph Company. Mr. Browne's speech had special reference to the *employés* of foreign companies and administrations, and he commented upon the fact that by the introduction of the telegraph national frontiers had in a sense been obliterated. The observations of the chairman respecting remuneration and promotion were referred to by several speakers, one of whom indicated, as an example of the defective organisation, the case of two officers present, both in the same class, although one had seen four years' service only and the other 25 years' service. Reference was also made to the anticipated pressure of work consequent upon the opening of the Exhibition this year as a reason for some additional monetary consideration. The chairman promised to exert himself to that end, but was unable to hold out much hope, owing to the deficient state of the finances. With reference to the chairman's allusions to the financial conditions of the Spanish telegraph service, we may refer our readers to a "Note" in *The Electrician* of January 20th last, p. 257, under the head of "Spanish Telegraph Statistics."

Technical Instruction for South-west London.—Mr. Anstie, Q.C., received at the Charity Commissioners' offices, Whitehall, on Monday, a large deputation from Chelsea, Pimlico, St. George's, Hanover-square, and Fulham, who asked for a grant of money from the City Parochial Funds in order to establish a technical institution in the south-west of London. The deputation included Lord Monkswell, Sir C. Dilke, Col. Howard Vincent, M.P., Mr. Whitmore, M.P., Hon. S. Holland, Sir A. Hayter, Mr. Antrobus, the Rev. F. Relton, the Rev. G. Blunt (rector of Chelsea), and the Rev. Prebendary Eyton (rector of Upper Chelsea). The Rev. F. Relton, in introducing the subject, said Earl Cadogan had offered a site upon which to erect the institution, and had left it to them to choose a suitable one. The site would cost £2,500, but Earl Cadogan had said that if they acquired the leasehold he would give them the freehold. There had been for about 20 years a small technical institution, which had resulted in the formation of Onslow College, the success of which had been very great. They were anxious that in the south-west of London there should be a technical institution such as was proposed for the north of London, the south of London, and the east of London. He could assure the Commissioners that there was a great deal of poverty in the south-west of London, and he might add that there was a large number of artisan dwellings in the locality, a fact which fully entitled them to a share of the funds. Mr. Antrobus, speaking on behalf of St. George's, Hanover-square, said the great advantage to be derived from the establishment of such an institution in the south-west of London was generally recognised. Mr. Anstie, in reply, said he could not give the deputation any definite answer; but if the locality could raise the sum of £50,000 and could come to some agreement with Onslow College, the Commissioners would give the proposal their consideration.

Execution by Electricity.—We reproduce the following article from the *Lancet* :—"The authorities of New York have come to the decision that henceforth all criminals sent to death for capital offences in their State shall be killed by the electric shock. The practice, once determined on by one State, is sure to be followed by other States; and, if the first experiments be considered successful, we may soon expect to see the plan widely, if not universally, extended. The idea which is at the bottom of this change is due, first to the popular belief that everything that is now to be done with rapidity must be done by means of electricity; and, secondly, that death by electricity is absolutely painless. That the electric shock can be applied to man in such a manner as to destroy life instantly and painlessly is beyond dispute. The shock can be applied at such tension as to rupture the veins, and even the right side of the heart. But in order to apply it with absolute precision it must be used in the most certain way, since it may seem to cause the death and yet may not kill. One of the most striking examples of catalepsy in our time was caused by a lightning stroke, which is the same as the shock; and the subject of the shock was so thoroughly mistaken for one dead that he was laid out for dead, and heard the sound of his own passing bell; yet he recovered, and lived many years afterwards to recount the strange experience. In experiments on the lower animals, it has also been observed that a shock sufficient to produce such complete prostration as seemed fatal was not so. The greatest care, therefore, must be taken, if the electric shock be used for destroying the lives of criminals, that the criminals be not buried alive after an assumed death. In the further consideration of this question the policy of the proceeding as well as the humanity of it requires to be taken into account. If the execution of criminals is to be maintained it must carry with it some degree of terror. If it does not, then, even in the eyes of those who are in favour of it, it will be looked upon as a solemn and cruel farce. It would be so, nothing more, nothing less. The argument for the Act is that 'it is a terror to evildoers'; but, as we once before pointed out, if the dread of suffering is to be taken away, if the transit from life to death is to be made more easy than the common modes by disease, then in some cases an actual premium will be put upon crime. In plain words, if the death penalty be right there is nothing whatever in the present system that is one whit too severe. Why, then, should the present plan be interfered with? Why should the gallows be made to lose its indefinable terrors? A new mode of executing will be sure to bring a new sentiment in respect to execution, and perhaps in respect to the executed. 'The man was *electrified* for the murder.' Will that do? At a moment when the question of the judicial act is itself in the balance, is it good policy to open a new era in the method of carrying into effect a tragedy for which our successors are sure to stamp us as barbarous, and against which many of the wisest and most cultivated of our time are raising an emphatic protest whenever the opportunity occurs?"

CONTINUOUS-CURRENT TRANSFORMATION.

BY R. PERCY SELLON.

(Continued from page 624.)

ARTICLE II.

In a previous article, published in *The Electrician* of April 13th, the merits and demerits of a system of electrical distribution based upon the employment of continuous-current transformers was briefly glanced at.

In the present article it is proposed to survey the past history of the continuous-current transformer, referring to publications and patents which have appeared upon the subject.

The first suggestion to utilise continuous currents for the purposes of transformation, so far as the writer has been able to trace, appeared in the *Comptes Rendus* de l'Académie des Sciences of Paris for the 23rd of November, 1874. M. Alfred Niaudet, in a pamphlet published in 1875, awards the credit of the invention to M. Gramme, father of the modern dynamo machine.

The following abstract from this pamphlet will be of interest:—

"M. Gramme, in the *Comptes Rendus* of the 23rd Nov., 1874, has shown that his apparatus can be used for transforming electricity. He employs for this purpose an armature wound with two circuits, one of fine and the other of thick wire, placed between the poles of a magnet. If the current of two Bunsen elements be sent through the thick wire the armature will begin to revolve, and as the result of this motion there will be produced in the fine wire coils a current of electricity, in the same manner as in an ordinary 'Gramme' machine. In this instance the secondary current has a higher electromotive force than the primary one, the ratio in the machine experimented upon being 8 to 1. It will be seen that we are dealing here with the transformation of electricity, and the change in the tension is analogous to that produced in the Ruhmkorff coil. With such an apparatus the current of two Bunsen cells could be transformed and made equivalent to a small current from 16 Bunsen or 30 Daniell cells, and employed in telegraphy. It is important to notice that the apparatus of Gramme admits not only of the transformation of low-tension currents into those of high-tension currents, but also of the reverse of this, viz., the transformation of a current of high tension into one of low tension. There is no gain of power by this transformation, because the increase in tension corresponds to a loss in volume of current, and *vice versâ*."

Here we find distinctly set forth the principle of transformation by means of continuous currents, and it is interesting as affording to those who regard continuous-current conversion as a creation of yesterday an apt illustration of the adage that "there is nothing new under the sun."

At this point, however, the matter appears to have dropped for some years, until we find it resuscitated, and (it goes without saying) patented, by the indefatigable genius of Menlo Park, followed, at no remote period, by that second parent of modern electric lighting, Lane-Fox, both of whom conceived the idea of a system of distribution based upon the use of these apparatus.

Just previously to the above, Gravier, in a patent bearing date 13th March, 1882, No. 1,211, describes "an inductor or transformer of currents by which a given current may be converted into a continuous or an alternating current either in tension or quantity." This consists of a Gramme ring, wound with two series of insulated wire coils, each series connected to a separate commutator. The collecting brushes upon the two commutators are placed at right angles to each other.

The passage of a current through the primary coils produces consequent poles in the ring; and, upon rotation being imparted, "the successive passages of the secondary coils over the consequent poles of the annular magnet will induce currents of electricity in those coils, which may be collected and utilised in any desired manner, or in lieu of revolving the ring the brushes alone may be revolved."

So far the apparatus is not a rotary transformer as ordinarily understood; under a modified arrangement, however, "a mass of iron is placed in front of the consequent poles of the magnet," so that when "a current of electricity is sent into the primary circuit (the brushes being suitably placed to obtain the effect desired) the ring will turn on its axis in order to obtain a position of stable equilibrium in front of the mass of iron. From the very fact of this rotation a current will be induced in the coils of the secondary circuit." The revolution is evidently intended here to be produced through the presence of induced poles in the "mass of iron" resulting from the consequent poles produced in the ring by the primary coils; the mass of iron thus virtually becomes an external exciting field.

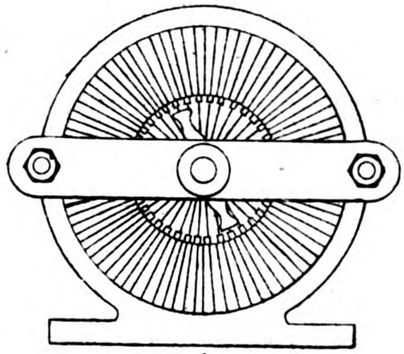

Fig. I.

Fig. 1 shows this device, the "mass of iron" being represented by the block placed horizontally across the ring. The claim is for "the arrangements of machinery above described, in which a ring is used to carry inductor coils and overlying induced coils for the purpose of producing electric currents."

Five months later, in a patent, No. 3,752, of August, 1882, Edison describes an invention which has for its object "the production of efficient and economical means for dividing an electric current of high electromotive force or tension into a number of currents of lower electromotive force or tension, and for making all the lamps, motors, or other translating devices operated by the currents of lower tension independent

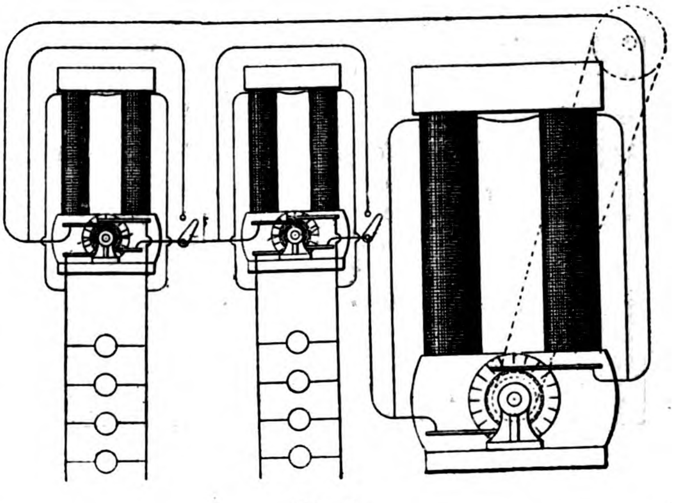

FIG. 2.

of each other. Such an arrangement enables a great saving to be effected in conductors, since a high-tension current can be used from the point of generation to near the point of generation, and the translating devices can be made independent by a multiple-arc arrangement."

After proceeding to describe how one method of doing this consists in interposing into a series circuit counter electromotive forces such as motors or secondary batteries, he states that by an alternative method it may be effected by introducing "combined electro-dynamic motors and dynamo-electric generators"

Digitized by Google

into the circuit. "Each machine has a cylindrical or annular armature core, wound with two sets of continuous coils, connected to two independent bar commutators." The primary armature coils are all in series, while low-tension multiple arc supply is obtained from the secondary armature coils. The field magnets, which are common to both sets of armature coils, are wound on a shunt with the supply coils, and the machines are thrown into and out of circuit by opening or closing a short-circuiting switch across the terminals of the primary.

Fig. 2 shows the arrangement.

A claim is made for "the combination with one or more dynamo or magneto electric machines supplying a main circuit with a current of high tension, of two or more combined electro-dynamic motors and dynamo-electric generators arranged in series as motors in such main circuit, and supplying as generators independent circuits, means for cutting out of the main circuit any one of such combined motors and generators, and multiple arc circuits from the said independent circuits, having translating devices arranged therein, and including field coils of such combined motors and generators, all substantially as hereinbefore described."

Under a second patent, taken out twelve days later (August 17, 1882), numbered 3,949, the same inventor describes another means of continuous-current conversion, consisting in the employment of "induction apparatus constructed as hereinafter described," virtually stationary transformers, wound with primary and secondary coils, "located between the main circuit and the translating devices, and transforming a continuous current of high tension into a continuous current of low tension."

Two commutators—one in connection with either set of coils—are fixed upon a common shaft and "revolved by any suitable means, as, for example, by an electro motor or a spring or weight actuated by mechanism." Upon the revolution of the common shaft, rapid reversals of polarity are produced in the primary coils, thus inducing currents alternating in direction in the secondary coils. These secondary currents are, however, commutated synchronously with the primary currents, so that a continuous current is produced in the secondary supply circuit.

A claim is made for conducing the tension of a continuous current for use in a "resumption circuit having translating

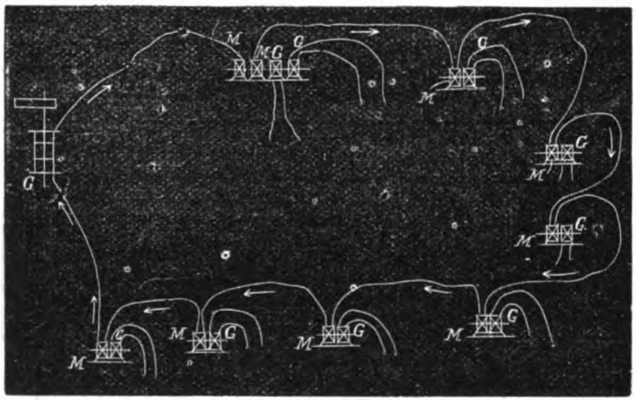

Fig. 3.

devices arranged in multiple arc, below that of the main circuit, by means of induction apparatus placed between the said circuits, and consisting of intermediate double-wound magnetic cores, and commutators for simultaneously changing or advancing the connections of the circuits with the winding of such cores, all substantially as hereinbefore described with reference to the accompanying drawings."

This is followed by a patent, No. 3,692, dated July, 1883, of St. George Lane-Fox.

This sets out that "in dealing with distribution of electricity on a large scale, the question of transmission from localities where motive power is cheap is of very great importance. To transmit electricity over long distances it is essential that high pressure or high tension be used, so as to keep down the cost of conductors, and to reduce the loss in such conductors; but for well-known reasons it is best not to distribute electricity at high tension. I have therefore devised the following system, to combine the advantages of high tension for long-distance transmission with the advantage of a lower tension for distributing in centres of supply."

Lane-Fox then proceeds to describe a system based upon the use of rotary transformers, and adds that "secondary batteries may be used to keep the electromotive force constant and act as reservoirs."

Fig. 3 illustrates the drawing attached to the specification. M represents the motor, G the generator circuits.

The claim is for "the system of electrical distribution hereinbefore described."

(To be continued.)

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

(Continued from page 654.)

If a current traversing an inductive circuit under a periodic impressed electromotive force is made to pass through another circuit which acts electro-dynamically upon a movable circuit conveying another current proportional in strength to, and agreeing in phase with the periodic variation of potential difference at the terminals of the inductive circuit, such an arrangement will, if it can be realised, afford a means for obtaining a numerical measure of the power taken up in the inductive circuit.

An electro-dynamometer having its fixed coil composed of thick wire and its movable coil of fine wire, each circuit being independent, is most usually called a *wattmeter*. The examination of the circumstances under which the wattmeter can and cannot be used to measure the power expended in a circuit subject to simple periodic electromotive force, leads to some very interesting questions.

If the thick and thin wire coils of a wattmeter are traversed by two independent steady unidirectional currents the force on the movable coil is at any instant proportional to the product of the strengths of these two currents. If each of these cur-

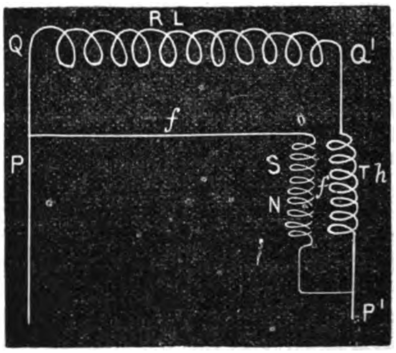

Fig. 35

rents are simple periodic currents the force varies with the product of the instantaneous values, and the compound curve formed by taking as ordinates the products of the corresponding values of these separate current strengths at each instant is itself a simple periodic curve, provided that the two component currents have constant amplitudes, equal period, and fixed difference of phase. Let a wattmeter be supposed to be joined up to an inductive circuit (*see* Fig. 35); let R and L be the resistance and inductance of this inductive circuit between the points Q Q'; let the thick wire coil *Th* of the wattmeter be joined in series with this inductive resistance, and let the fine wire coil *f* of the wattmeter of resist-

Digitized by Google

ance S and inductance N be joined to the points P P′; let the thick wire coil be of negligible resistance and inductance in comparison with the circuit Q Q′. If a simple periodic electromotive force operate on the double circuit between the points P and P′ we shall have a current flowing in R and S; it is required to calculate at any instant the currents in R and S respectively. Consider simply a divided circuit (Fig. 36) in which R and S are the branches; let x be the current at any instant in R and y that in S, and let i be the strength of the current in that part of the circuit just before it divides; in other words, i is the main current which is divided into x in the induction resistance, and y in the fine wire coil of the voltmeter. Let e be the potential difference between the points P P′ at the same instant, and let X, Y, I, and E be the maximum values of all these quantities respectively. We assume that i is a simple periodic function of I, and we then write $i = \mathrm{I} \sin p t$, where $p = 2\pi n$, n being the

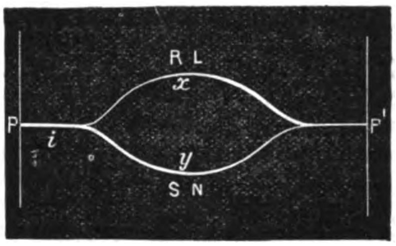

Fig. 36.

frequency. Applying the fundamental equation to each circuit, we see that

$$\mathrm{L}\frac{dx}{dt} + \mathrm{R}x = e;$$

also

$$\mathrm{N}\frac{dy}{dt} + \mathrm{S}y = e.$$

Accordingly,

$$\mathrm{L}\frac{dx}{dt} + \mathrm{R}x = \mathrm{N}\frac{dy}{dt} + \mathrm{S}y;$$

but by the principle of continuity

$$i = x + y$$

always, since there can be no accumulation of electricity at P or P′; hence

$$x = i - y,$$

and, hence,

$$\mathrm{L}\frac{d(i-y)}{dt} + \mathrm{R}(i-y) = \mathrm{N}\frac{dy}{dt} + \mathrm{S}y,$$

or

$$\mathrm{L}\frac{di}{dt} + \mathrm{R}i = (\mathrm{L}+\mathrm{N})\frac{dy}{dt} + (\mathrm{R}+\mathrm{S})y;$$

but

$$\frac{di}{dt} = \mathrm{I}p\cos pt,$$

and

$$i = \mathrm{I}\sin pt.$$

$$(\mathrm{L}+\mathrm{N})\frac{dy}{dt} + (\mathrm{R}+\mathrm{S})y = \mathrm{I}\,\mathrm{L}p\cos pt + \mathrm{I}\,\mathrm{R}\sin pt,$$

or

$$\frac{dy}{dt} + \frac{\mathrm{R}+\mathrm{S}}{\mathrm{L}+\mathrm{N}}y = \frac{\mathrm{L}p\mathrm{I}}{\mathrm{L}+\mathrm{N}}\cos pt + \frac{\mathrm{R}\,\mathrm{I}}{\mathrm{L}+\mathrm{N}}\sin pt.$$

This differential equation is of the type

$$\frac{dy}{dt} + \mathrm{P}y = \mathrm{Q},$$

where Q is a function of t. The solution of this will be found in "Boole's Differential Equations," p. 38, and it is

$$y = e^{-\mathrm{P}t}\left(\int \mathrm{Q}e^{\mathrm{P}t}dt + \text{const}\right),$$

e being here the base of Nap. logs. and not impressed E.M.F.

In the case before us

$$\mathrm{P} = \frac{\mathrm{R}+\mathrm{S}}{\mathrm{L}+\mathrm{N}},$$

and

$$\mathrm{Q} = \frac{\mathrm{R}\,\mathrm{I}}{\mathrm{L}+\mathrm{N}}\sin pt + \frac{\mathrm{L}p\mathrm{I}}{\mathrm{L}+\mathrm{N}}\cos pt.$$

The integral of $e^{\mathrm{P}t}\sin pt$ and $e^{\mathrm{P}t}\cos pt$ are required. They are as follows:—

$$\int e^{\mathrm{P}t}\sin pt = \frac{e^{\mathrm{P}t}(\mathrm{P}\sin pt - p\cos pt)}{\mathrm{P}^2+p^2},$$

and

$$\int e^{\mathrm{P}t}\cos pt = \frac{e^{\mathrm{P}t}(\mathrm{P}\cos pt + p\sin pt)}{\mathrm{P}^2+p^2};$$

hence it follows that

$$\int e^{\mathrm{P}t}\mathrm{Q}\,dt = \int e^{\mathrm{P}t}\frac{\mathrm{R}\,\mathrm{I}}{\mathrm{L}+\mathrm{N}}\sin pt + \int e^{\mathrm{P}t}\frac{\mathrm{L}p\mathrm{I}}{\mathrm{L}+\mathrm{N}}\cos pt$$

$$= \frac{\mathrm{R}\,\mathrm{I}}{\mathrm{L}+\mathrm{N}}e^{\mathrm{P}t}\frac{(\mathrm{P}\sin pt - p\cos pt)}{\mathrm{P}^2+p^2} + \frac{\mathrm{L}p\mathrm{I}}{\mathrm{L}+\mathrm{N}}\frac{e^{\mathrm{P}t}(\mathrm{P}\cos pt + p\sin pt)}{\mathrm{P}^2+p^2};$$

and

$$\mathrm{P}^2 + p^2 = \frac{(\mathrm{R}+\mathrm{S})^2 + (\mathrm{L}+\mathrm{N})^2p^2}{(\mathrm{L}+\mathrm{N})^2}.$$

Therefore we have by substitution

$$y = \frac{\mathrm{I}}{(\mathrm{R}+\mathrm{S})^2 + (\mathrm{L}+\mathrm{N})^2p^2}\left\{\begin{array}{l}\mathrm{R}(\mathrm{R}+\mathrm{S}) + \mathrm{L}(\mathrm{L}+\mathrm{N})p^2\sin pt \\ +\overline{\mathrm{R}+\mathrm{S}}\,\mathrm{L}p - \mathrm{R}\,\overline{\mathrm{L}+\mathrm{N}}\,p\cos pt\end{array}\right\},$$

or

$$y = \frac{\mathrm{I}}{(\mathrm{R}+\mathrm{S})^2 + (\mathrm{L}+\mathrm{N})^2p^2}\left\{\begin{array}{l}(\mathrm{R}^2 + p^2\mathrm{L}^2 + \mathrm{RS} + \mathrm{LN}p^2)\sin pt \\ \qquad + (\mathrm{S}\,\mathrm{L}p - \mathrm{R}\,\mathrm{N}p)\cos pt\end{array}\right\}.$$

Since the original equations are symmetrical in x and y, R and S, L and N, the value for x is given by changing R to S and L to N in the equation for y.

This equation for y gives us the strength of the current in the fine wire coil, and it shows us that the phase of the currents x and y in the branch circuits differs from that of the main current i by an amount which depends on L, N, R and S. In order to exhibit this in a simple form we may direct attention to a simple trigonometrical transformation.

Lemma.—The function $\mathrm{A}\sin\theta + \mathrm{B}\cos\theta$, where A and B are constants, may otherwise be written

$$\sqrt{\mathrm{A}^2+\mathrm{B}^2}\sin(\theta+\phi),$$

where

$$\tan\phi = \frac{\mathrm{B}}{\mathrm{A}}.$$

Draw any rectangle (*see* Fig. 37) O P, O Q, and draw a pair of rectangular axes, O X, O Y, through O. Project the

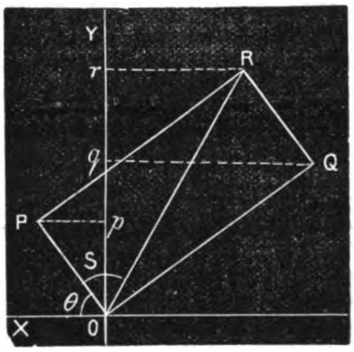

Fig. 57.

points Q, R, P on O Y. Then by geometry if $\mathrm{POX} = \theta$, and $\mathrm{POR} = \phi$,

$$\mathrm{O}r = \mathrm{O}p + \mathrm{O}q,$$
$$= \mathrm{OP}\sin\theta + \mathrm{OQ}\cos\theta,$$
$$= \mathrm{OR}\sin\mathrm{ROX} = \mathrm{OR}\sin(\theta+\phi);$$

hence

$$\mathrm{OP}\sin\theta + \mathrm{OQ}\cos\theta = \mathrm{OR}\sin(\theta+\phi)$$
$$= \sqrt{\mathrm{OP}^2+\mathrm{OQ}^2}\sin(\theta+\phi).$$

But

$$\tan\theta = \frac{\mathrm{OQ}}{\mathrm{OP}};$$

hence

$$\mathrm{A}\sin\theta + \mathrm{B}\cos\theta = \sqrt{\mathrm{A}^2+\mathrm{B}^2}\sin(\theta+\phi)$$

where

$$\tan\theta = \frac{\mathrm{B}}{\mathrm{A}}.$$

Returning then to the equation for y, the coefficients of $\sin pt$ and $\cos pt$ in the equation are respectively $\mathrm{R}\,\overline{\mathrm{R}+\mathrm{S}} + \mathrm{L}\,\overline{\mathrm{L}+\mathrm{N}}\,p^2$, which represents the A, and $(\mathrm{R}+\mathrm{S})\mathrm{L}p - \mathrm{R}$

Digitized by Google

$(L+N)p$, which represents the B, in the above. Squaring each of these expressions, and adding the results, we obtain as a result

$$\{(R+S)^2+(L+N)^2p^2\}\ (R^2+p^2L^2);$$

hence we finally arrive by substitution at the equation for y

$$y=\frac{I\sqrt{R^2+p^2L^2}}{\sqrt{(R+S)^2+p^2(L+N)^2}}\sin(pt+\theta).$$

where $$\tan\theta=\frac{B}{A}=\frac{(R+S)Lp-R(L+N)p}{R(R+S)+L(L+N)p^2},$$

or, $$\tan\theta=\frac{(SL-RN)p}{R(R+S)+L(L+N)p^2}.$$

In this form the equation for y shows us that the phase of y is *ahead* of that of i, or that the main current lags behind the current in the branch S, provided that S L is greater than R N; and since the expression for the current x is perfectly symmetrical, we can write it down at once, and it is

$$x=\frac{I\sqrt{S^2+p^2N^2}}{\sqrt{(R+S)^2+p^2(L+N)^2}}\sin(pt+\theta')$$

where $$\tan\theta'=\frac{(RN-SL)p}{S(R+S)+N(L+N)p^2},$$

and it is obvious that if S L is greater than R N, $\tan\theta$ is positive, and $\tan\theta'$ is negative.

If S L = R N, then there is no lag, and the branch currents x and y agree in phase with the main current i.

The general result is, therefore, this—when an impressed electromotive force acts on a circuit which branches into two, having each self but no mutual induction, the main current lags behind the impressed E.M.F. in phase, and the two branch currents respectively *lag behind* and are *pressed ahead* of the phase of the main current.

The question then arises, under what circumstances does the branch current which is in advance in phase of the main current get so much ahead that it comes into consonance with the phase of the impressed E.M.F.?

To settle this question, we shall have to discuss briefly the question of the compound impedance of branch circuits.

(To be continued.)

JUVENILE LECTURES.

THE APPLICATION OF ELECTRICITY TO LIGHTING AND WORKING.*

BY W. H. PREECE, F.R.S.

Lecture I. (continued from page 693.)

We are to-night connected in this room with the Grosvenor Gallery in Bond street. The Grosvenor Gallery has a central station where a very large dynamo is at work, from which electricity is supplied to different parts of London; many thousand lamps are fed in a great many clubs, theatres, and private houses; they are all lit up by the currents generated underneath the Grosvenor Gallery. The Grosvenor Gallery Company, through their engineer, Mr. Ferranti, have very kindly undertaken to supply us to-night with a current. The current is supposed to be a very dangerous one; in reality it is not; there is no electric current that has ever been produced that is one-tenth as dangerous as a steam boiler, and all these currents, however immense they may be, are very simply controlled, and very easily brought within the region of safety. There is no doubt that with the apparatus that is now being handled in this room, if anybody were deliberately to put one wire in his mouth, and the other in his hand, he would have the funeral service performed over him in two or three days, but those who know what they are about no more handle electric light wires carelessly than they put their hands in a furnace or their noses in boiling water. We acquire experience by practice, and we know by this time pretty well how to deal with electric currents. Now you see in the lower arrangement there that safety catches are being put in, which render any accident quite impossible. Passing through each of those boxes there is what is called a "cut-out" safety fuse, or safety valve, and should, from any accident, anything go wrong in this theatre, or in any way with the system outside the theatre, the safety fuses would burst, and would so remove all danger from inside. The switch has now been turned, and by it the current from the Grosvenor Gallery has been brought within our reach. You will see that between what appears to you as the top carbon (but which is in reality the bottom carbon of the two) and the bottom one there is playing, apparently, a shower of minute fragments of something, but which are in reality innumerable minute flashes of lightning; there is a constant uninterrupted shower of electric shocks passing that produce that intense brilliancy, and that very bright appearance. There is intense commotion, a terrible surging about of matter in a molten condition. Well that arc that you see is produced by the currents from the Grosvenor Gallery. They are alternating currents of electricity; currents that are constantly and suddenly circulating backwards and forwards. The arc that we have at this other end of the room is a direct-current one, and it is now projected on to another sheet of paper, where you see a different form of arc altogether. This arc is produced by the direct current from a battery. You will see the form is quite different from that in the alternate-current arc. You heard a peculiar hissing sound just now; that is a peculiar phenomenon in arc lamps that has attracted a good deal of attention from physicists, but nobody has yet arrived at a satisfactory conclusion as to the cause. The lamp sometimes sings and sometimes hisses, and while thus behaving it produces an intense and variable inverse electromotive force that has to be overcome before the current can produce a steady and silent arc. You will notice in the upper carbon of this form of lamp a kind of cup, or "crater." The lower carbon forms a kind of point—a raised surface, and between the two there is on the projection that which appears as a glow, but which in reality has very intense heat, reaching, as I told you, a temperature of 8,500° F. In these two projections you have, I think, within my experience for the first time, shown in public an alternate-current arc and a direct-current arc at the same time, so that you are really able to see what I do not think most people have seen before.

There are a great many different arc lamps. I have not time to bring before you all the various lamps that I might have secured for your inspection. There is the Brush lamp, that for a long time lit up the streets of our City, and I sincerely hope very soon is going to light up the City again. There was the Jablochkoff lamp, that lighted up our Thames Embankment, and which can be seen on going down the Strand, at the Tivoli Restaurant, not far from here. The offices of the *Daily Telegraph*, in Fleet-street, and many other places, are lighted up by different lamps, many of them excellent. Our experience of the last two or three years at the exhibitions has taught us that there are a great many different kinds of arc lamps, but all these arc lamps are lamps so constructed that they cause the pair of carbons to be fed to be kept together as they consume, at the same rate as they do consume. The mechanism is of great delicacy, it acts with great promptitude, and the one that we have here to-night is one of the last and one of the best; it is known as the Brockie Pell lamp. The lamp now at work is a Brockie-Pell; it feeds with great rapidity, with great convenience, and is one of the steadiest lamps we have.

There are objections to the arc light; it is extremely dazzling and irritating to the eye. Although the arc lamps we have here to-night are of the very best of their kind, and are certainly almost steady, still they have little irregularities in their action, and, worst of all, they throw intense shadows. The light from them is not very well diffused; still the light is very brilliant, and it raises the envy of a good many people. For instance, the Brush Company were once establishing a light in

* A course of three Lectures delivered before the Society of Arts on January 4th, 11th and 18th.

Digitized by Google

the neighbourhood of Cork, and an Irish farmer was remarkably struck by the appearance and the steadiness of the light, so he came to the engineer in charge and asked him, as a great favour, if he could kindly tell him where he got his oil from.

I must now go from this to the next branch, the glow lamp. For this lamp we do not use platinum, but we use carbon, so fine that although I have probably one hundred or more in my hand, they feel no heavier than a feather. These extremely fine filaments of carbon are made, with very great care, from cotton. I cannot show you the whole operation of making carbons and some of the preliminary operations connected with the making of the lamp; but owing to the kindness of the Anglo-American Brush Company, their manager, Mr. Sillar, is here to-night, and we shall have the pleasure of seeing how the whole operation of the manufacture of one of these glow lamps such as we have above us now is carried out. The carbons have already been formed, but the first process is that the cotton fibre is carefully tied and wrapped around pieces of carbon, as you see. It is then placed in a furnace and carbonised. After being thus prepared, a glass tube of special quality, selected for the purpose, is used to form the glass globe. Mr. Donaldson will take a piece of the glass tube before you, and will blow it into the shape similar to the lamp I hold, which is of the very familiar pear-like form. The carbon filament with then be fixed in the glass bulb, the latter will be exhausted and sealed, and the whole process be passed through before your eyes. I must first of all show you why it is necessary to take all this care. We have in front of the board one of these carbon filaments suspended, and we will now pass a current through it, and the carbon filament is raised to incandescence; it combines with the oxygen of the air, it is at once consumed, and, as you saw, we only had a light for a few seconds. Now, in order to make that light permanent, it is necessary to enclose the carbon filament in a glass globe, and to exhaust from that glass globe all the air, or as much of it as possible, and then, instead of having a life of a few seconds, the life of a lamp frequently continues for 4,000 hours or 5,000 hours. The first process, as I said, in making an incandescent lamp, after the carbon filament has been prepared, is that of blowing a glass bulb. The blow pipe has now been put on, and the intense heat of the Bunsen burner raises the glass to incandescence, to a soft, plastic condition, so plastic that the manipulator can do with it just whatever he likes. Having got the glass to this particular shape, the filament will be placed inside it, first of all mounting the filament, which is an operation requiring a great deal of care and great skill in handling. It is an extremely pretty operation, and I beg to call your attention to it. The carbon is fixed inside a fine spiral of platinum, which is at the same time subjected to an intense current which decomposes the oil or the hydrocarbon in which it is placed, the carbon deposits on the carbon filament, and cements it to the platinum spiral. That is called mounting the filament. When that is done, the filament is fixed in the glass globe, and the platinum and glass are fused together. The brilliance of the platinum can be seen during this operation, and it is very pretty. I do not know how it would have been possible for us to have glow lamps if it had not been for the fact that the coefficients or rates of expansion of platinum and glass are practically exactly the same, and the result is that when the platinum and glass are combined together, as they are in a glow lamp, the two contract and expand at the same rate, and the result is there is no leakage; if there had been leakage through the glass it would have been quite impossible to have made a glow lamp. The success of a glow lamp depends upon the vacuum produced, and the next process is to cement the lamp so far to a vacuum tube connected to a mercurial air pump. The one before you is Mr. Lane-Fox's. It would have been also impossible to have produced these beautiful glow lamps without the mercurial air pump, so that the success of electric lighting and its perfection depend upon, first, the similarity of expansion of glass and platinum; and, secondly, upon our power of producing a vacuum. As it takes ten minutes or a quarter of an hour to carry out the process of exhaustion, I will proceed with other portions of my subject, and presently, when the time is ready, Mr. Sillar will inform me, and we will light up the lamp that has been made before you this evening, and, I hope, with success. The operation we have just seen is one that has been just as interesting to me as it has been to you. There are very few who are permitted to see this operation. We once had it before in this hall, when General Webber read a paper on glow-lamps, but with that exception I am not aware that the manufacture of glow-lamps has ever been shown in public before. It is most wonderful to watch the marvellous way in which glass can be twisted and turned to our ways and to our wants; and the skill with which the blower is able to manipulate glass in its plastic condition, and to shape it in any form he likes, is an operation which never ceases to excite one's wonderment. The form of lamp that is being made before us is of the ordinary size that we see used generally, but there are a great many different sizes of glow-lamps. For instance, here is a very small lamp; above me you will see, if I may call the small one a dwarf, there is a giant glow-lamp. It is a lamp invented by the Hon. Charles Parsons; it is made by the Sunbeam Lamp Company, of Gateshead, and is called the Sunbeam Lamp; it has the same proportion to an ordinary lamp that an ostrich egg has to a hen's egg, and the light from it is of equally large proportion, as you see now the current has been turned on to it. It gives a light of 400 candles, but it is rather too brilliant, I see by your faces, and we will go back to our old friends of the ordinary size. There are also above us lamps of various sizes; there is a five-candle, ten-candle, sixteen-candle, twenty-candle, and a hundred-candle lamp. Here also are a fifty-candle Swan lamp, a sixteen-candle Swan, and an eight-candle Swan lamp. These are the ordinary sixteen-candle lamps; these are being burned from the Grosvenor Gallery. Here is a miner's lamp which is supplied with a current by the Schanschieff battery, the same as I showed you at first; the peculiarity of this arrangement is that when the battery is turned upside down the light goes off, the zincs and carbons occupy one-half of the cell, and the solution the other half, the zincs and carbons being at the bottom, and the battery is not excited unless contact is made with the carbons and zinc. Such a battery as this will maintain its lamp for 12 or 13 hours. There are several forms of the Schanschieff battery. Here is a portable form, and lamp connected with it by a flexible wire, which can be used when travelling; or in the night, when you want to know the time, you can have a lamp and battery like this by your bedside, and you can turn it upside down, and produce a light, see the hour, and turn the battery back.

These glow-lamps are used for different purposes and ways. They may be used with care, they may be used recklessly; their duration depends a good deal upon the care with which they are used. A practised eye, one who is accustomed to deal with electric lamps, can tell at a glance when the lamp is raised to a proper incandescence; but there is a point in all lamps that is a sign of danger, and indicates "breakers (or breakage) ahead." Whenever in an electric light installation a glow-lamp begins to show a blue effect, then breakers are ahead; the current must be reduced or other steps taken. I want to show you this blue effect, which is extremely pretty, and I want you to see the gradual stages through which a lamp passes, from long life to death, or rather to a very short and merry life. We can make the life of a lamp just exactly what we like; we can make a lamp last a minute, or we can make it last a hundred years, and the number of years of its duration is simply dependent upon the current employed. I have here a glow-lamp, and I pass a current through it. There is no blue effect at present; the current is increased, and the carbon filament is raised to a high state of incandescence. In such a state it would not last for a long time, not more than ten minutes or a quarter of an hour; but it does not show the blue effect yet. On further increasing the current the blue effect appears, though I doubt whether it is visible to many of the audience; a little more current is put on, and the blue effect is very marked, the globe itself looks very brilliant, and, there, the current has been increased until the filament has parted.

It is always better when making an observation or expe-

Digitized by Google

riment to know what you are going to see, so that you can direct your attention to exactly what is being done or to what you want to know. If I put another lamp through the same experiment you will be better able to understand this blue effect, and see just that point where the lamp is about to give out. The current is now on, and is being gradually increased; the lamp is now intensely blue, and—there, it has gone in the same way exactly as the other one did. The way in which lamps burst is sometimes very beautiful; they disintegrate, they seem to volatilise, and the substance of the lamp is projected with great force against the side of the globe. On the table there are several beautiful specimens showing this effect.

The glow-lamp in process of manufacture before you is now being unsealed from the pump; it is now exhausted, and we will pass a current through it so as to raise it to incandescence. The current is now on, and you see the lamp burns with full brilliancy. The next experiment is rather a cruel one, because it is wilful destruction. I will not destroy the lamp that has just been made before us, for I will keep it as a momento of this evening. I want to show the safety of the electric lamp. Many people imagine that there is a great deal of danger about it. I will take a handkerchief, and in it place a lighted lamp, when, on the globe being broken, the carbon filament instantly goes out, and there is no damage to the handkerchief, or the slightest appearance of scorching or heating upon it. On breaking that lamp you hear a report. That is due to the vacuum, which, on sudden rupture, the air rushes in to fill. These lamps will not only burn in air, but will actually burn in water. Here I have a lamp which on placing in a bowl of water continues alight in the water just as well as in the air. You can imagine what an immense boon that is to our divers and others who unfortunately have to work under water for our benefit.

I will not attempt to occupy your time in speaking of the beauties of this wonderful light, how it removes really poison from our air, how it is very good for sore eyes, because it burns with such steadiness that those who work under it really never find, in any shape or form, any inconvenience or discomfort to the eyes. It is extremely cleanly; it does not fill the air we breathe with noxious fumes. People are little aware of it, but it is a very simple calculation to show that thirty gas-burners produce a gallon of water in an hour, so that if you have thirty burners in a shop, for instance, alight for six hours, six gallons of water are produced, and the water can very often be seen running down the cold windows of shops. That water absorbs sulphur and sulphuric acid, and when deposited on books and decorations destroys them. If we could only get the electric light cheap, delivered at our doors, then everybody who has an idea of luxury and comfort would at once take it.

I want now to show you some of the dodges of the electric light. First I will show you that by the action of a cut-out an excess of current is prevented from injuring the lamps. A cut-out is inserted so as to protect a group of lamps here, and on a large current being sent you hear a crack, and the lamps have gone out; the safety fuse has perished in performing its duty. To prove this we will renew the cut-out, and on the proper current being turned on you see the lamps are sound. Here is an electric cigar lighter. I raise this up and the wire in front of it comes to a state of incandescence, and I have there, as you see, sufficient heat to light my cigarette. Some years ago I had my daughter's doll's house, which was furnished by heaself, fitted up with the electric light, and I thought that some of my younger hearers to-night, who were still in the doll age, would appreciate the way in which a doll's house can be lighted up by electricity. You now see the doll's house illuminated; it has a hall-door lamp, which lights up on the opening of the door; the house has rooms furnished, occupied with handsome dolls, and fitted with every kind of contrivance; the doll who occupies the drawing room has the convenience of a portable lamp which she can move about wherever she likes, and each room and the kitchen has a particular form of lamp.

I have also here a model of that famous ship the "Captain," which was wrecked off Cape Finisterre. The model has been fitted with electric light, and you now see the mast-head light, the red light for the port side, and the green light for the starboard side. There are high jinks going on in the saloon by the aid of the electric light; and there is also a search light which can be used for looking for the advance of the enemy. A beautiful phosphorescent effect is produced upon the water, which is covered with blue cotton wool in which a lamp is placed causing really a very pretty illustration of what the phosphorescence of the sea is like.

Here I have an apparatus for heating curling tongs by electricity; here is a flat iron treated in the same way, and here is a kettle in which the current is carried to boil water. I travel a good deal, and I always carry in my travelling bag a battery like this, which is one of Pitkin's secondary batteries. It is light and extremely convenient; I can strap it on my shoulder like an opera glass. To this is attached a reading lamp which I fix in my waistcoat, and to the astonishment of my fellow travellers, when the shades of evening are beginning to set, I I take out the lamp and put it in operation so. My reading lamp is thus provided. and it is fixed in the most convenient position, for the light falls just where it is wanted, it does not offend the eye, and enables me to read the smallest print. I have always got with me my own light, perhaps much to the annoyance of my fellow passengers, and with the electric light machinery at my own house I have little or no trouble in re-charging the battery, or keeping it in order. The Pitkin battery is also applied to a miner's lamp. The effects of this wonderful power of electricity that we possess can be shown in many ways, and there are many other applications to lighting which I should have liked to mention, but I have much exceeded my allotted time, and must leave the rest of my subject until next Wednesday, when I will show you electricity in another form.

(To be continued.)

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

THURSDAY, APRIL 26TH—*continued.*

Cross-examination of Mr. R. P. SELLON resumed: You began by describing that in your filament you used cellulose?—Yes.

Do you know what the chemical constituents of cellulose are?—I am not a chemist; but it is a woody fibre, oxygen and hydrogen being the main constituents. The wood fibre is the carbon. I think the chemical formula is $CbH^{10}O^{5}$.

In the lamps submitted as the result of the manufacture of your corporation there is a carbon filament within a receiver made entirely of glass, through which the leading wires pass, and through which the air is exhausted?—That depends on your definition of a filament. In the sense that filament is now a common term, applicable to the burners of any incandescent lamps, what you say is true.

With your filament prepared in the way you have described, are the defects remedied by the flashing remedy—the defects in the deposit of carbon?

Mr. JUSTICE KAY: He said so.

Mr. ASTON: Now, you have said that the production of the slender carbon material requisite for the Edison lamp according to his process was unknown at the date of Edison's specification?—The carbonising of such filaments.

The persons who would be employed in the manufacture of electric lamps would be persons accustomed to electricity in the first instance?—Not necessarily. I do not see that there need be any necessary association between a knowledge of electricity and a knowledge of incandescent lamp manufacture.

Suppose a person who read Edison's specification tried to make an electric lamp, would not an electrician, in your own opinion, be a person likely to be consulted, and likely to give directions as to the putting of the parts together?—He certainly would, I imagine.

It is a fact, is it not, that in works where electric lamps are now made it is by no means unusual to have gentlemen like yourself capable of understanding the application of electricity?—At the present day no doubt it is.

On the Court resuming after luncheon,

Mr. ASTON continued his cross-examination of the witness as follows:—

I understand you are the manager actually operating at the defendants' works?—No; I am not the manager, I am the chief electrician.

And your duties would be directed, I suppose, to giving directions as to the proper way in which lamps should be manufactured and tested?—Yes, amongst other duties.

Am I right in saying that in reading Mr. Edison's specification you did not overlook the fact that he directed attention to a prior specification, regarding which he says that in a prior specification, dated June

17th, 1879, 2,402, he has set forth the evidence of resistance by long lengths of platinum wires?—I did not overlook that.

Is it not a fact that in that specification Mr. Edison refers to the operation of what we call "flashing," electrical heating, or exhausting for the purpose of expelling the gas?—He does refer to the driving out of the cruder gases, no doubt.

That was by passing the electric current through the material operated upon, and so enabling the gas to be expelled?—Yes.

And he says carbon can be treated in that way?—Yes.

Taking into consideration what you find in Cheesborough, do you not think an electrician like yourself in 1879 would know you might very advantageously improve by treating in this way and by driving out the cruder gas?—I think it is extremely probable.

I presume also an electrician acquainted with Cheesborough would in all probability use this process too for the purpose of improving his burners?—My recollection is that Cheesborough does instruct you to drive out the cruder gases—those are his words.

Therefore, an electrician in November, 1879, acquainted with those two processes would know he could improve the burner considerably by finishing off the carbonising in this way?—No answer.

Mr. JUSTICE KAY: Is not this all argument?

Mr. ASTON: I admit that it is so.

Resuming the cross-examination, the learned counsel asked: Do you think in any of these cases in which you got a very friable light in your burner you might have obtained a less friable or fragile result if you had more temperature?—I think the result of the carbon would have been less at a lower temperature; but, on the other hand, the quality of the carbon would be much more of a loose form, like charcoal carbon.

Suppose you had a loose form of carbon, and wanted to make it better suited for your purposes of burning, you could have known you might have subjected that to Cheesborough's process?—As a matter of fact I did not know. I cannot say.

Suppose you had known at that time Cheesborough's process, what would have been the result?—A manufacturer of lamps who is aware of Cheesborough's process, or the process of electrical heating, would probably have followed it.

And would not that have improved the specimens?—It might.

Might you not, by your knowledge now of Cheesborough's process, improve every one of those specimens?—No doubt it would have rendered them less fragile.

But what you have done has been to follow strictly your own reading of Edison's specification, and you have given the result?—That is what I have endeavoured to do—to follow Edison's specification.

Is it true that Edison indicates in his specification that it is advisable not to have a filament that is liable to crack and break, but a filament that is homogeneous and made of carbon?—I understand the expression is as homogeneous as possible; but he has previously told us that you can increase your resistance by mixing up with your putty carbon volatile and non-conducting matters, such as oxide of zinc, and he then goes on to say he prefers to put in as little of that non-conducting matter as possible, and so obtain his filament—in fact, his filament is to be as homogeneous as possible.

Do you not think the three specimens which you give me here, if carefully manipulated and put into the lamps, might produce good results?—Those specimens might with difficulty be mounted, but the further difficulty that would meet you would be that you would not be able to obtain your vacuum owing to the fact that the platinum had undergone a process of carbonisation, and is thereby rendered porous.

Is it not a fact that you always have, in the delicate processes you have to superintend and direct, to make allowances and correct inconveniences by your experience?—Oh, yes, obviously.

You heard the evidence given by Mr. Edward Gimingham?—I heard a portion of it. From what I heard of his evidence, and what I have read in the shorthand notes, according to my understanding of Mr. Edison's specification, he did not follow out Mr. Edison's instructions, and therefore I think the lamps produced were not Mr. Edison's lamps within the meaning of this specification.

He supplemented Mr. Edison, you think, by information outside of his specification?—I think he did that. To mention one respect in which he did not follow the specification, the platinum wires were not subjected to a process of carbonisation under the conditions prescribed, as I undersand, by Mr. Edison.

In the specimens produced by you, R P S 11 and 12, have you not a comparatively rigid stick of carbon?—It is rigid, no doubt.

Have you caused that lamp to be lit?—I have seen this lamp burning for several hours.

Do you not know that Mr. Swan spoke of his experiment as an experiment which would require to be perfected in order to be successful in operation?—He may have done so.

Mr. ASTON having quoted from the books on the subject, the witness said: I have read that before.

At that time, February 4th, 1879, was there any indication that he had solved the problem?—He does not appear to have thought so.

Mr. ASTON was about to quote from a letter at page 79 of the third book—a letter from Mr. Swan.

Mr. FINLAY said if his learned friend intended to put these things into the process he would not object; he assumed the learned gentleman was going to call Mr. Swan.

Mr. JUSTICE KAY: What kind of evidence can this be? Mr. Swan does not appear to have thought the experiments successful. If you oblige me to take such things down I shall be obliged to remark upon them.

Mr. ASTON: When did your company first make electric lamps?—At the end of 1879 or the commencement of 1880. They acquired the patent rights of Mr. Lane-Fox, who had for some time previously been engaged on that work.

I want to know when the company as a company first made or sold lamps in this country which were invoiced by the company?—I believe in 1880, certainly in 1881; but I cannot speak to the definite date.

When did you begin to make lamps after the process you describe?—About the year 1884.

Mr. WILLIAM CROOKES, examined by Mr. GRAHAM, deposed: I am a Fellow of the Royal Society, President of the Chemical Society, and Vice-President of the Society of Telegraph-Engineers. I have devoted great attention to electricity during the last thirty years. In 1864 Mr. Sprengel first published his book, which was described in the *Transactions* of the Chemical Society shortly afterwards. Between that year and 1872 I used Sprengel's pump in a very large number of investigations, and it has been in constant use to my knowledge.

I believe you performed those experiments which Sir Frederick Bramwell described as wonderful?—Yes.

And those experiments required vacuum matter of extreme perfection?—Extremely high.

You have been familiar with the working of close sealing for a great many years?—I have.

When did you first give your attention to the manufacture of incandescent lamps?—About the year 1880.

And since then you have seen every form of incandescent lamp that has been introduced to the market?—Yes.

Witness was then examined as to certain experiments which he had made, and his evidence had not concluded when the Court rose at four o'clock.

The further hearing of the case was adjourned till Monday.

MONDAY, APRIL 30.

Mr. WILLIAM CROOKES was further examined by Mr. Graham as follows:—

On Thursday I omitted to ask you whether you did not light your own house in the year 1881 with incandescent light?—I lighted my own house in Park gardens with electricity in 1881, and I have continued to do so ever since.

What sort of lamps did you use in 1881?—I used every kind of lamp. I commenced with lamps of my own manufacture, and then used Edison's lamps and the Maxim lamp. Afterwards I used Swan and Lane-Fox's lamps.

In the process of carbonising, Sir Frederick Bramwell stated that in his opinion sand would do?—From my chemical knowledge I feel convinced that sand would not do for such a delicate filament. Although I knew what the result would be I put over 100 filaments in dry sand, and packed the crucible tightly with the sand, gluted the cover with fire clay in the way adopted by metallurgists when they wish to keep air out of the crucible, then raised the temperature gradually to a full yellow heat. I exhibit specimens of paper, cotton, linen, card, cellulose and wood, before carbonisation, and I also exhibit the remains which were got from the sand after carbonisation. Everything is burned except the card, which contained so much inorganic impurity that it has left a coherent ash, which is not carbon; the whole of the carbon is burned out.

The witness then entered into a minute description of the experiments which he had made in attempting to carry out the directions in Edison's specification, the result being that no successful lamp was produced in any case, although by introducing certain modifications in the process it was found possible to make a lamp capable of burning for a brief time; but in no case were the results of a commercial character.

Have you ever seen lamps made according to Edison's directions only on the market?—Certainly not.

In your opinion does Edison's specification contain directions to enable capable workmen in 1879 to make a working lamp?—I do not think the specification contains sufficient directions to enable me with my present skill to make a working lamp.

Mr. JUSTICE KAY: Did you see the lamp you spoke of in Paris lighted?—I saw it lighted for a few minutes.

As to Deprez's process, you have been carefully through it?—I have been.

In your opinion are there any passages which refer to passing the current through?—Many of the passages refer to incandescent experiments in contradistinction to an arc experiment. There are 19 experiments which are incandescent, about three which are arc, and the others doubtful.

Contrast the process with that of Cheesborough?—Contrasting the description given with the description in Cheesborough, I should say the processes are identical and the results are identical.

In your opinion if this paper had been put into the hands of competent workmen at the date of Cheesborough's patent, would they have been enabled to get the same results?—I consider this a very fair description, and a workman could not have failed to get the same results if he had tried it.

Turning to Sidot's paper, what do you say about the material from the description as compared with Cheesborough's material?—It is very similar material, produced in a similar manner.

As a matter of fact, are there any occluded gases in Cheesborough's material?—There would be, certainly; it could not be quite free from them.

Have you made any experiments in heating with hydro-carbon gases?—I have made a great many experiments and have succeeded practically with all of them.

Did you try any hydro-carbons with which you did not succeed?—No; I succeeded with all the hydro-carbons that I tried.

Digitized by Google

What do you understand by hydro-carbon?—A compound consisting entirely of hydrogen and carbon with no oxygen present.

Did you try any substances consisting exclusively of hydrogen, carbon and oxygen which failed? I tried formic acid, which failed. Glycerine failed also. I tried mixing alcohol and water together until it got to the point at which it failed; but that is not a chemical compound.

Mr. JUSTICE KAY: Was that because there was too much water or too much alcohol?—It failed when the water got to a certain point.

Witness was next referred to page 15, line 48, of the specification, and asked, speaking as a chemist, Have you formed any idea of what are included under the terms "infusible substances, non-conductors of electricity?"—I should think substantially the list I have handed to you. [This list consisted chiefly of metallic oxides and some sulphates.] To the best of my knowledge, the whole of these bodies are included under the words "infusible non-conductors." There is a difficulty in answering the question, because I do not know the meaning of the word infusible. Of course, everything, I imagine, would be fusible if you heat it high enough.

I believe you carried out certain experiments with reference to Cheesborough?—That is so.

What was your first experiment?—My first experiment had reference to line 5. I took a cylinder of lime, and drilled a hole through it. The cylinder was about ⅜ of an inch diameter and ⅝ inch long. The longitudinal hole was about $\frac{1}{50}$th of an inch in diameter. From the centre I passed a stick of Carré carbon half a millimetre in diameter. I then clamped the two ends of the carbon rod which projected at the ends to conducting wires, placed the whole in an atmosphere of coal gas bubbling through benzol, and passed an electric current through the rod of carbon. The carbon was raised to a good white heat; that heat raised the surrounding silica of lime to a good red heat, and carbon was deposited in the pores of the cylinder. The lime was originally white; the dark colour is produced by the carbon deposited. I then cut the carbonised lime into small rods. [Rods produced.] I mounted one of those in a lamp, and passed the current through it. The lime originally was a non-conductor of electricity, but introducing carbon into its pores made it a conductor. The current was turned on, and it was raised to a red, and then to a full yellow heat. At that temperature the oxygen in the lime united with the carbon, carbonic acid was formed, depressing the mercurial gauge, calcium was volatilised, depositing on the sides of the glass, and the stick broke. The light evolved during this decomposition showed calcium lines on the spectrum. The carbonic acid depressed the gauge, the pump was set to work a little longer, and the gas collected. By chemical tests I showed it was carbonic acid. I have the results here. I repeated that experiment in the presence of the gentlemen I have named, and this is the lamp. [Lamp produced.] I have here an unbroken lamp, produced in the same way, with which the experiments will be repeated when desired. The temperature at which this lamp broke was much below the ordinary temperature of an incandescent lamp. I tried experiments with three things besides lime, selecting therefrom the best, which I have prepared. I used a cylinder of fireclay of similar dimensions to those given to the lime, passed a stick of carbon through, and tried it in the same way. The metals were volatilised, the carbon united with the oxygen, forming carbonic acid, the gauge was depressed, and the gas was tested. The lamp was coated with a black deposit, and the conducting portion broke. I next tried magnesium, and the result was the same. Asbestos, zirconia, alumina, silica, and thoria were also tried, and the result was the same. I am quite certain the effects produced in these cases would have been produced with the other specimens on the list. I did not choose those most likely to fail. I took them for a fair trial.

Cross-examined by the ATTORNEY-GENERAL: Regarding the experiments you put in this morning. When did you conduct that series?—Not many days ago.

A little nearer than that?—I cannot recollect the precise time, but it was since hearing Sir Frederick Bramwell's evidence.

In your examination in chief you told us that you succeeded last Saturday in making a filament. Is it not the fact that a series of experiments were conducted on Friday and Saturday last?—Oh, certainly not.

When were they made?—A few days before the commencement of this trial.

You said, Mr. Crookes, that was done in order to test what Sir Frederick Bramwell said?—Yes.

When did you do that?—If you can tell me the date of Sir Frederick Bramwell's examination I will tell you.

He gave evidence on the 17th April?—Well, it was done the same night.

That would be last Tuesday night week?—Yes.

Was this experiment carried out on the night of the 17th?—It was.

Have you communicated the result to your solicitors?—I communicated with them afterwards.

The next day?—I think I wrote a letter to Mr. Sellon, the principal witness for the defendants.

Were you present when Mr. Gimingham and Dr. Fleming were examined?—I was.

Speaking of Edison's patent broadly, you say there are not sufficient instructions to enable workmen to carbonise a filament?—I say so.

And, secondly, carbonising a filament of platinum wire produces porosity?—Yes.

Am I right in saying that these are your two main attacks on the Edison patent?—I think one most important of all is the impossibility of making a putty tar filament.

These are the three main attacks?—Yes, I think they are.

Did you try to make a lampblack tar filament before the 17th of April?—Yes.

When did you first try?—It is impossible to give the exact date—some weeks ago.

Did you keep a record of those early experiments?—I did.

Did anybody assist you in your experiments?—My assistant helped me.

Anybody else; taking the 17th April down to those completed last Saturday, had you anybody assisting you?—If you do not refer to the instances in which I repeated experiments in presence of the gentlemen named, I had not anybody assisting me.

Are you acquainted, or are you not, with the carbonising process?—I am acquainted with it.

Were you in 1879 acquainted with carbonising processes?—I was acquainted with the process of making charcoal for gunpowder, but I was not practically acquainted with more delicate processes.

Were you, or were you not, as a chemist, acquainted with what was called the process of carbonisation?—I was.

I understand you to represent that the idea of carbonising these filaments in sand is an absurdity?—It is an absurdity.

You do not suggest that either sand or charcoal are mentioned in the specification—simply carbonisation?—Simply carbonisation.

What is the reason why, as compared with charcoal packing, sand is an absurdity for packing those filaments?—Because there would be so much air in the interstices of the sand that the delicate filament would be burned up.

So much air in the interstices of sand as compared with the interstices of carbon, I presume you mean?—No.

As compared with what?—There would be practically the same amount of air in the interstices of the sand as in the interstices of the carbon, and there might, perhaps, be more in the interstices of the charcoal than the sand.

You stated just now that packing with sand was an absurdity as compared with packing with charcoal for carbonising a filament. Tell me what it is in sand, as compared with charcoal, that makes it an absurdity, or an impossibility to carbonise filaments in sand?—When the temperature rises to the carbonising point and the oxygen in the interstices of the charcoal is used up by the charcoal itself, its action on the filament is prevented. But, when the sand is heated up to the same temperature the oxygen in the pores of the sand has no carbon to attack, except a small quantity in the filament.

Then that, for very broad purposes, is a sufficient answer to the question of what I call an absurdity, and what you call an impossibility?—I think so.

Shown box and asked—Will you swear that these filaments have not been carbonised in sand?—Certainly not. I am not going to swear anything about them.

A few minutes ago you told me that to carbonise a filament on sand was an impossibility. If so, will you tell me why you will not say these have not been carbonised in sand?—Impossibility is rather a stray word. I did filaments like that myself in sand, and I might do an enormous number of such. I should trust, however, to the outside filaments being burned up, and taking all the oxygen and a few filaments in the inside might be left. I was not by any means playing tricks.

We will see about playing tricks before this case is over. Did you mean just now to tell me it was absurd or impossible, and could be done or could not be done?—You put the words into my mouth. I used them in reference to the process in this patent.

I wish to have an answer to the question. When you answered the question I put to you a few minutes ago, did you mean that it could be done or not done?—I am speaking in reference to the patent, and I understood your question had reference to it. I mean that the process could not be carried out practically.

The Court then rose for luncheon, and, on reassembling,

The ATTORNEY-GENERAL continued his cross-examination of Mr. Crookes as follows: Before I pass from carbonisation of sand, would you kindly look at those lamps [Shown lamps.] Will you undertake to say that the carbon filaments in those lamps have not been carbonised in sand?—It is impossible to say by looking at them how they have been carbonised.

Do you represent that for the purposes of carbonising filaments any packing at all is necessary?—No.

Was it not in 1879 well-known that you could carbonise filaments of carbon, or any other kind of carbon, according to the cubic contents of the vessel in which they are carbonised?—It is self evident to a chemist that if the amount of the oxygen in the vessel is very small and the amount of carbon in the filaments it contains very large, and no further oxygen comes in by the time the whole of the contained oxygen was used up in burning some of the filaments, there would be a few filaments left untouched.

I do not think you are doing yourself justice, Mr. Crookes. Was it not well known that it was simply a question of the relative bulk of the carbonising vessel and the bulk of the wood or other material put into it?—Yes; that would be well known to a chemist, but not to workmen.

Was it not well known to those accustomed to carbonise?—I suppose it was. I cannot answer for myself definitely, but I suppose it would be.

What was the size of the vessel in which you attempted to carbonise, Mr. Crookes?—It was a small-sized clay crucible, the smallest crucible which would take these filaments in.

How many filaments did you put in?—Over one hundred.

Will you please tell me as accurately as you can the relative volume of material you put into the cubic contents of the vessel?—It is impossible to say.

What was the specific gravity of the wood or material you used?—I did not take the specific gravity of it or any part of it.

You are sure you put 100 filaments in?—More than 100.

Cannot you, as a skilled chemist, give me an idea of the specific gravity?—I really cannot; I should have to refer to my books on the subject.

Was it not perfectly well known by people accustomed to carbonise that

Digitized by Google

twelve drams of carbon required 112,000 centimetres of air for their complete combustion?—I will take that from you as a scientific fact.

Was it not perfectly well known to people who carbonised?—I cannot say.

Was it not elementary chemical knowledge that these were the proportions required for combustion?—It might be calculated by scientific men, but I do not know, it is impossible to tell you.

Did you know, or did you not know in 1879, that a very large multiple of the number of times of filaments of carbon were required to complete burning?—I did.

The exact quantity you do not know?—I know it is against many chemical facts; I have not every figure in my brain, but a few minutes' calculation would give the result.

I am not asking about carrying in your head a few minutes' calculations. Was not the calculation a matter of elementary chemistry?—Of course it can be calculated out by any chemist, but I do not know many people who would carry the calculation in their heads.

Whether it was elementary chemical knowledge or not, it could be ascertained by reference to text books?—It might.

Did you ever happen to measure or weigh an ordinary filament such as that described in the books?—No, I do not think I ever have. It would be a very small fraction of a grain.

Assuming it is an eighth of a grain, is it not a fact that, roughly speaking, three cubic inches of air would be required to complete combustion?—I suppose you are correctly informed. I will take it if Prof. Dewar says it is so.

Until these experiments, had you, for yourself, made filaments or any small things?—I have.

Successfully?—Yes.

Packing charcoal is what you yourself use?—Yes.

Where did you get your information from?—With my chemical knowledge it was obvious to me.

Was it not perfectly well known in 1879 that for the process of carbonisation it was a common experiment in process to pack things to be carbonised with charcoal?—It was not in the manufacture of carbon for gunpowder. I am not aware that carbonisation was carried on except for gunpowder.

Do you mean to say that carbon-electros were not commonly made, and commercially made?—Yes, of course; I forgot.

Was it not a perfectly well-known and common process for carbonising wood, or any material going to be made into a lamp, to pack it with powdered charcoal?—I do not know that it was common knowledge. I believe in some of those cases they packed it with sand.

I call your attention to the statement in "Watt's Dictionary of Chemistry," published in 1875, page 255?—The dictionary is a standard book, and perfectly correct in the statement to which you allude, which every chemist would know.

You are aware of those patents for carbonising various conductors, from 1845 downwards. Can you tell me one in which what I may call the process of carbonisation is described beyond the statement that it is carbonisation?—I cannot remember one, but I do not say there are none.

Was it not perfectly well known that the time carbonisation took depended on the character of the vegetable matter?—I do not think there was much difference. There might perhaps be in extreme cases a difference, but I do not think much.

Was it well known it should be slowly tried and slowly heated?—I do not think it was.

Having regard to the tar lampblack, would any chemist think of moistening such a substance as that with water?—Certainly not.

Tar and water will not combine, will they?—No.

Carbon and water will not combine?—No.

Look at this box. [Shown box]. You could not say these are not tar and lampblack filaments?—I cannot say.

Tell me with reference to any one of these exhibits 7, 8, 9, and 10, what was the resistance you ascertained before the lamp broke down? [Shown lamps.]—I took no resistance on those lamps.

You did not take the resistance cold in any case?—Not quite cold.

What current did those lamps break down respectively at?—I cannot say; they were only about white heat.

Do you know what the pressure was before the lamp broke down?—No; they broke down before I commenced to measure.

Witness was further examined by the ATTORNEY-GENERAL in regard to the porosity of platinum, and, in reply, said: I should like to explain that porosity is not produced by the action of the silicon or carbide on the platinum so much as by the action of the air on these compounds. If silicide of platinum is heated to the burning point of platinum the silicon burns into silica, which fuses and forms a sort of glaze on the surface of the platinum; but if the carbide of platinum is heated to a high temperature, the carbon melts, forming a gas, leaving the platinum porous. For that reason I should think the action of carbon would leave a much more porous platinum than the action of silicon.

The Court then adjourned till Tuesday.

TUESDAY, MAY 1ST.

Mr. CROOKES was futher cross-examined by the ATTORNEY-GENERAL. He stated—I am myself a patentee of electric incandescent lamps, and have a patent dated March, 1881, for an incandescent lamp containing a carbon filament. I proposed to purify the carbon by hydrochloric acid. I did not think it necessary at that period to give any directions as to how the filament was to be carbonised.

Do you represent that there has been any publication between April, 1880 and September, 1881, when your complete specification was filed, of any directions respecting the mode of carbonisation?—At the date of the patent incandescent lamp factories were in full operation, and it was well known how to carbonise. That patent was addressed to the people of these factories and not to the public. Edison published full particulars in the patent subsequent to the one sued upon, and that I fancy was between the two dates you named. His patent of 1879, No. 5,127, contains directions for carbonising. So also does his patent of 1880 for a bamboo filament.

Do you suggest that there is anything in either of the passages you have read as to the process of carbonising that was not perfectly well known to the people who carbonised in the year 1879?—I cannot answer. Edison knew all about it.

Have you practically carbonised electric arc carbons prior to 1879?—No, I never made any.

Had you used any Lane-Fox lamps?—Not in 1881. I have only used them recently.

You say you had used it as early as 1881?—It was a mistake if I did, but I do not think I did.

When did you use Lane-Fox first?—In the Paris Exhibition I was one of the jurors, and I was on a sub-committee to examine all the incandescent lamps, and on that sub-committee I examined and reported on the Edison lamp, the Swan lamp, the Lane-Fox lamp, and the Maxim lamp.

Did you know that the filament and broom used by Lane-Fox was treated by the Cheesborough process?—No.

When you tried those experiments which you described yesterday you put a substance upon the tar and lampblack filament?—That was one experiment. I made a great many experiments.

I am referring to that in which you used a filament of tar and lampblack?—It was a tar and putty filament.

You told us that the best filaments you could make were made on the palm of your hand?—Excuse me, I said that I had a large percentage of carbons where the substance was so fragile that I could not succeed to roll it out in any other way.

[Shown lamp]. Is not that a filament which you made by rubbing it in the palm of your hand?—No.

How did you make it?—I rolled it between two bits of glass.

[Shown three lamps.] Do you suggest that these filaments are uniform filaments?—No.

None of them are uniform?—No; they are full of cracks.

I am not speaking of cracks. Are they uniform in the sense of being of uniform diameter?—No.

Are you aware that Edison points out that it is important that the wires or filaments should be uniform in size throughout?—Yes. I did my best to get that.

If not uniform in size, you would have much greater heat at the narrowest cross-section?—Yes.

You would have the points of light unequal, which would be corrected or improved by the Cheesborough process?—Yes.

And the more "un-uniform" the more liable to break down?—Yes.

Did you try fireclay with a uniform filament?—I tried with the most uniform filament I could get.

You have just told us that these filaments were not uniform. Have you tried it with a uniform filament?—I have tried it with a filament which was rolled out uniform, but in curling it to make a horseshoe, it has cracked in many places and therefore became "un-uniform."

I wish an answer to my question. Have you tried with a uniform filament?—It is impossible to answer yes or no without giving an explanation; it would cause an erroneous impression.

You have given an answer that the filaments you took were as uniform as possible. Have you tried what Edison described as a uniform filament?—I have not.

[Shown lamp now put in.] I suggest to you that that is an ordinary carbonised parchmentised thread lamp, coated with silicate of alumina. Do you suggest when such a lamp was running that the presence of silicate of alumina or silicate of magnesium would break down the filament?—This lamp is useless.

I am aware of that; it is open, I mean a perfect lamp of that kind?—It is coated with fusible silicate of alumina. If you ran it very high reduction would take place.

Do you give the same answer as to another lamp now shown you, coated with silicate of magnesium?—Yes.

That would be useless?—As a practical lamp, yes.

If it was heated to anything like what I should call ordinary incandescence the result would be that there would be destruction of the carbon?—Yes.

[Shown two lamps with globules of silicate in them.] Would you undertake to say that these are not coated in exactly the same way, one with silicate of magnesium and the other with silicate of alumina, running with the electric current so high that the silicate of alumina was fused and came off in globules with the filament perfectly uninjured?—No; it is not parallel to the Edison case.

I am not asking about Edison. You said a moment ago that both the lamps now worked, Nos. 27 and 28, so coated, would be useless on the ground that when heat was applied to raise them to incandescence, the silicate would attack the carbon and destroy the filament?—That is my experience.

Then will you undertake to say that the other two lamps now marked 29 and 30 are not two lamps which have been coated, like 27 and 28, with silicate of alumina and silicate of magnesium, and raised by the electric current to such a heat as actually to fuse the silicate, and yet to leave the filament absolutely uninjured?—It does not need much heat to fuse silicate of soda. This lamp is marked "of soda."

Would you answer my question?—I say under these circumstances it would not be possible to do it.

Will you undertake to say that that is not so?—I cannot undertake to say that.

Digitized by Google

A moment ago you said, in regard to 27 and 28, which are identically the same lamps, that it was impossible they could run. How do you reconcile that with your present statement?—I had the Edison design in my mind, and you say I am not to refer to the Edison patent.

I cautioned you twice about their not being the Edison patent. I put to you these actual lamps, and told you it was a parchmentised thread, and asked you whether these two lamps could be burned as lamps, and you said no. Will you tell me what are the circumstances to which you now refer?—The circumstances are these; in the Edison filament it is an extremely porous filament, which will suck up the fused silicate like a sponge, and allow the chemical action between the silicate and the carbon to take place. These filaments are very fine horny non-porous filaments, which will allow the fused silicate to rub off easily. Moreover, there are very many silicates of these different substances varying in fusibility, and I suggest, although I cannot say that it is so, that they may have chosen very fusible silicates for these experiments.

You gave evidence as to rolling the filament out on a glass plate after sifting finely powdered fire clay over it. In other words you got more or less of this silicate of alumina incorporated in the surface of the filament?—Yes.

Did you try any filament coated with the actual substances mentioned by Edison?—These are cerium, lime, and magnesium.

Will you produce any lamps in which you used cerium, lime or magnesium before carbonising?—No.

Did you coat any filament with cerium, lime or magnesium before carbonising?—No; I did not.

Why did you not try one of the things Edison has mentioned?—I knew perfectly well that the result in this case would to my mind prove exactly the same thing as in the other case, and this was so much easier.

Why did you not put cerium in your test?—It is such an out-of-the-way thing; probably I forgot it at the time.

You said yesterday that there was no difference, assuming sufficient heat to be used, between Sidot's and Cheesborough's processes. You said, "So long as the heat is sufficient it does not matter how the heat is produced?"—Yes.

Would external heating correct the irregularities in the slightest?—Certainly not.

For incandescent electric light do you suggest that anybody before Cheesborough had pointed out the advantages gained by internal heating in hydro-carbon gas?—I do not think it had been pointed out except in the paper which has been put in.

Pardon me for asking you to answer my question one way or another, and I will give you an opportunity of dealing with the exception. Do you suggest that anybody had pointed out the advantage for incandescent lighting of internal heating in a hydro-carbon atmosphere?—No, I do not. I think I first consulted Desprez in 1849, a year or two after the publication of his statement in the *Comptes Rendus*. I began the experiments which led to my patent of 1881 some time in 1880. When I began to make incandescent lamps I did not specially consult Desprez; I knew it very well. I have made Desprez carbons.

Witness was then cross-examined in detail as to the Deprez filaments, and the time he kept them in the hydro-carbon bath.

Re-examined by Sir HORACE DAVEY: I remember the lamp which was put into my hand yesterday, and said to have been made by the Edison Company, with a bamboo filament. Assuming that was so, I said it was within the description contained in the second claim of Edison's patent. Assuming that the bamboo lamp has been made since the date of the patent, and in accordance with the second patent of 1880, that would not be a lamp which in my judgment was made in accordance with the terms of Edison's specification. As to my experiments in carbonising, I put a hundred or more filaments into the crucible, and I filled it up with sand.

Was that a fair experiment for the purpose of testing whether sand would answer the purpose?—I tried to do it as fairly as possible. The heat to which it was subjected in that experiment was the ordinary heat which would be used for carbonising and obtaining a successful result.

You were referred to the expression used by Edison—a closed chamber. Was any patent known to you or is known now for closing a chamber for the purpose of carbonising except that adopted by you of gluting with Stourbridge clay?—There is no better method. There was nothing in the directions contained in Edison's specification which would lead a workman to know he was to fill the crucible entirely with the materials to be carbonised. I should not think it would be in accordance with the ordinary mode of carbonising.

Have you any doubt after the cross-examination you have been subjected to on the subject that, as a practical means of producing filaments, carbonising in a crucible padded with sand would not be a practical mode, although you might now and again get a filament?—It might be possible to get a few out of a hundred carbonised in sand.

You told us as to rolling out the putty thread. Did you try several experiments as to the best mode of rolling out the putty thread?—I remember an enormous number of experiments. I rolled the thread on a plate of polished glass with a spatula. Then I tried a plate of fine ground glass with a spatula; then I tried both polished and ground glass as a basis; then a piece of plate glass polished and ground, and rolled the thread on that. I rung the changes on all these. Edison does not give any instructions how the filament is to be rolled. I tried such methods of rolling out as are known even at the present day. The putty thread would not bend without cracking. I consider that that cracking would be fatal to the use of putty thread in a lamp. It is possible to bend it without cracking by keeping the mixture in a plastic state by constant vibration. Then you can coax it round, but that is a very difficult and a very tedious process, and quite impracticable as a manufacturing operation. I was at work for several days before I struck on that plan. Ultimately I tried rolling in the palm of my hand. That was in one case only. Everything else failed. The filament was so frail. That was in the case of camphor.

The Court then adjourned.

WEDNESDAY, MAY 2.

The re-examination of Mr. Crookes was continued by Sir HORACE DAVEY, as follows:—

Referring to your patent of 1881, No. 1,422, was the object of that patent to get rid of impurities in the manufacture of carbons, and not any method of carbonisation?—Yes.

At the date when you took out your patent can you say whether there had been any advance in the knowledge of carbonising those filaments?—There had been a very great advance in the knowledge of the people to whom the patent was addressed; I will not say the general public or ordinary general manufacturers of electrical apparatus—they would not be interested in getting rid of the impurities from carbon—but the patent was addressed to people engaged in making lamps.

Witness further said: With regard to the lamps containing parchmentised threads coated with silicates of alumina and magnesium, silicate of alumina is the name given to a large class of bodies containing silica acting as the acid, and alumina acting as the base, in various proportions. These silicates differ considerably in fusibility. *Mutatis mutandis* the same explanation applies to silicate of magnesium. Silicate of soda is a combination of silica and soda; soluble glass, I think, it is called. It is much more fusible than ordinary glass. Soda is the oxide of sodium; silica of soda is very fusible for a silicate. Much depends upon the proportions between the silica and the soda; the more soda present the more fusible will it be.

Sir HORACE DAVEY: It was suggested that in the lamps shown the silicates had fused and run off, instead of attacking the carbon?—Yes.

Would it make any difference in the silicate, when exposed to high temperature attacking the carbon, that the thread had been parchmentised, and was of a dense homogeneous character?—It would make a very considerable difference.

Would the experiment shown in these lamps be a fair test of what would happen in a coated filament prepared in accordance with Edison's specification?—I do not think it could be called a fair test.

There is no direction in Edison's specification, for example, with regard to parchmentising?—None at all.

And would parchmentising make a material difference in the character of the carbon?—It would make an enormous difference.

If the carbon were of a coarse-grained character would it be attacked by the silicate sooner or later?—Very much sooner.

And if it were dense it would take a longer period?—Very much longer.

Would there be any practical advantage in making a practical lamp in putting on silicate of aluminium and melting it off?—I have experimented very largely in making these filaments, and I have found, without exception, that anything put on the carbon diminishes its power of lighting.

What is the advantage of putting anything on it at all?—I do not see any advantage.

Having regard to the description by Deprez of the material which was in use in preparation, was the material which you exhibited as produced by you following, according to your understanding of it, Deprez's experiment, the same material or not?—It was exactly the same material.

Take Cheesborough's description of the material. Is the material you exhibit, in your judgment, the same as that of Cheesborough?—The experiments of Deprez are the same as these, the same words apply, the material is the same in its physical qualities and properties.

And the process is the same?—Yes, the process is the same.

Prof. EDWARD FRANKLAND, examined by Mr. GRAHAM, said: For five or six years past I have lighted my house at Reigate with incandescent lamps supplied to me by the Swan Company, at Newcastle. I have also used lamps made by other makers, but for several years I used only the Swan lamps. I was much interested in the electric light, and made a point of seeing all the installations I heard of. In December, 1880, I saw an installation of incandescent lamps at Mr. Spottiswoode's house. They were Mr. Swan's lamps, and Mr. Swan was present and explained the process to the company. The lamps were burning the whole day. They were practical lamps. Soon after, I saw an installation of Lane-Fox's lamps at Bridge-street, Westminster. That was early in 1881. The first Edison lamp I ever saw was in the Paris Exhibition of 1881. In this country I first saw an Edison lamp at the Crystal Palace in 1882. I obtained a specimen of the lamps used from Mr. Sprague. I examined the lamps carefully, as I was chairman of the jurors. I produce the lamps given me on that occasion as a specimen of the Edison lamp then exhibited.

Mr. JUSTICE KAY: I presume the platinum wires here have not been upon it when it was carbonised?—I should think not.

Examination continued by Mr. GRAHAM: In my opinion that lamp was not made according to Edison's specification.

The ATTORNEY-GENERAL objected to a general question of that kind.

Mr. GRAHAM: Will you point out in what respects it is different?—In the first place it is made from a bamboo fibre, which is not mentioned in the specification 4,576. Secondly, the filament must have been carbonised by some process by which great precaution was taken to prevent its oxidation. It is an exceedingly fine filament, which would have burned up if it were not very carefully protected from oxidation during the carbonising process. And I find no directions for so protecting such a filament in Edison's specification 4,576. Next the filament is not

Digitized by Google

fastened to the platinum wires—if, indeed, it is fastened to them at all—by the method described in the specification. And lastly, the filament is not coiled and has no resemblance to the drawings. I have never seen anything nearer to Edison's specification than that lamp upon the market. I was in court when Mr. Crookes was examined, and read his evidence in the notes. I agree with him substantially. I saw the results of the experiments of Mr. Crookes with a cotton thread properly carbonised. I saw the thread after it had been carbonised, and I think I saw it actually put into the lamp and exhausted. I did not see it actually made into a spiral; it was made into a horseshoe. The horseshoe was very fragile. I have myself made experiments. I tried to roll out a thread or filament from a mixture of tar and lampblack with a steel spatula upon a glass plate, but could not succeed in reducing the diameter below a millimetre or about $\frac{1}{25}$th of an inch. I subjected splints of boxwood, deal, ash and cork, also threads of silk, cotton, and flax, and thin strips of paper to Sidot's process for one hour. I have made carbon filaments by forcing a mixture of lampblack, pitch, and tar through a fine hole in a drawplate. I have repeated Deprez's process with pencils of boxwood charcoal. I have also submitted a carbon filament prepared on Sidot's process and mounted in a lamp to Deprez's process. I have also made numerous trials of flashing in hydrocarbon gases and liquids, following Cheesborough's directions, but every attempt to reach a temperature of anything like 7,000° F. resulted in the destruction of the filament. The melted pitch destroyed the filament at all temperatures. With respect to the filaments I made, I did not carbonise any of them, but saw them after carbonisation. I did not see the filaments put into the crucible, but when it was opened it contained a quantity of ash, some powder, and part still in the form of filament. There was no packing in that experiment. I have not carried out any experiments on Edison other than those mentioned. I was present in Mr. Crookes' laboratory when the experiments with non-carbonising non-conducting substances were carried out. I think they were made on Monday, the 16th of April, this year. I saw the carbon filament which had been coated with fire-clay, and carbonised either before or after coating, put into a lamp, and the lamp ignited by a current. I viewed that filament through a spectroscope, and at a certain point of the emission I saw a bright spark, indicating the volatilisation of silica and aluminium. I also noticed that the gauge of the Sprengel pump fell at the same time two or three inches, showing that some gas had been evolved. I did not examine the gas, but in a previous similar experiment Mr. Crookes informed me that he had done so. The vacuum was as nearly perfect as a Sprengel pump can give us. When the spectral lines appeared the filament broke and the interior surface of the lamp became dim with a deposit. The phenomena I saw were caused by the reduction of the alumina to aluminium and the reduction of silica to silicon, with the simultaneous production of carbonic acid or carbonic oxide gas, or both, which caused the depression of the mercury in the Sprengel pump. This took place, because at that temperature there is a stronger affinity for oxygen than either alumina or silica. The breaking of the filament was caused by the oxidation of its carbon and the consequent conversion of a portion of it into gas. I have seen the operation of mounting repeatedly. I have seen the platinum wire come out of the carbonising vessel after the process was completed. That was at Mr. Crookes's within the last few weeks. The platinum wires were rough, and I should think, from their appearance, porous and very brittle, so that in mending one of them it broke off. I should say they had been carbonised with packing of charcoal and lampblack. I did not make any chemical analysis of the platinum.

Have you anything to say as to the use of platinum wires which have been carbonised in electric lamps?—They will be quite inapplicable for incandescent lamps on account of their porosity and brittleness—*i.e.*, if any portion of such were projected outside the lamp. A carbon filament within a receiver made entirely of glass was known in Swan's lamp, and in the same lamp the leading wires passed through the glass, and I believe the air was exhausted from the interior of the lamp.

At the date of Edison's specification do you know whether the word filament had acquired any technical signification?—Not to my knowledge in connection with electric lighting. The word had been used in various senses, but chiefly in botany, to describe the stem of flowers or anything that had a small cross-section and considerable length. A thread might be called a filament.

Referring to Cheesborough's specification, as a chemist would you say what substances are included under the words "infusible substances, non-conductors of electricity"?—Lime would be one, fireclay another, and many of the oxides of the metals, which would be properly described as infusible. Of course, all of them may be fused at a sufficiently high temperature, but they may be described generally as infusible.

The Court then adjourned for luncheon, and, on resuming,

Prof. FRANKLAND, in answer to Mr. GRAHAM, said: I was present when Mr. Crookes carried out Deprez's process, and saw the materials produced. I made an examination of those materials, and comparing them with the materials of Cheesborough's process I say they are identical.

Referring to the passage at the bottom of page 80, do you understand that to be an incandescent or arc experiment?—It is a little uncertain.

Coming to Sidot's process have you compared any of the carbons in the manner there directed?—I have.

What do you say of his carbons for incandescent lighting?—I say the carbons so formed are identical with the carbons produced by Deprez and Cheesborough's processes, and I say Sidot's filaments are well adapted for the manufacture of incandescent lamps.

Cross-examined by the ATTORNEY-GENERAL: You were examined, I think, at the last trial?—I was.

That was in the year 1886, two years ago?—I think so.

Since the last trial have you made any experiments yourself upon either of those two points?—No. I have seen platinum wires which have been carbonised along with the filaments in Mr. Crookes' laboratory, and upon the condition of those wires have founded my answers to-day.

Any information in the evidence you have given to-day is founded upon what you saw and observed for yourself at Mr. Crooke's?—Yes, it is, mainly.

Prior to giving evidence in 1886 you had made several experiments, had you not, in connection with the Edison patent?—Oh, yes, I had.

Where?—In the works of Messrs. Woodhouse and Rawson, manufacturers of incandescent lamps in a very large way at Hammersmith.

Did you say one word at the last trial as to the instructions to enable people to carbonise being necessary?—I have not my evidence before me, and cannot say.

Did you say one word directly or indirectly suggesting that the directions as to carbonising were insufficient?—I do not remember one way or another. Perhaps you will be good enough to point out in my evidence anything bearing on the point.

Have you read your evidence lately?—Not the whole of it, but a portion of it.

You have looked it through?—I have skimmed it.

You have no recollection of anything in it?—No recollection.

Did you say one single word about the porosity of the platinum wires?—No, I suppose I did not; I do not remember that point being raised.

Did you not say that with the directions none before Edison were sufficient to enable anybody to make an Edison lamp?—I daresay I might. I should say it now.

Did you consider that prior to the publication of Edison's specification the Swan lamp was the best embodiment of what was known?—It was an example of what was known, but it did not contain the best elements of what was known.

This F J B 1 Swan lamp was an exhibit at the last trial?—Yes.

It is a vessel made of glass?—Yes.

With a platinum leading-wire into the glass?—Yes.

Exhausted undoubtedly?—I have no doubt.

When did you first suggest that a lamp made like Swan's should have Sidot's filament in it?—I suggested it over and over again at the last trial.

Did you ever suggest to the scientific world, or publish in any way until you gave evidence at the last trial, that Sidot's filament could be put into what we call Swan's lamp?—No.

Did you produce at the last trial a filament made according to Pulvermacher's patent?—I produced a lamp in which there was a filament which had been made according to Pulvermacher's patent, but I did not see the lamp made, and I think I said so.

Who made it?—Professor Donkin, and part of the process was witnessed by another professional gentleman, but none of it by me.

You were endeavouring, were you not, to break down the novelty of Edison's invention?—No doubt.

Did you not say, giving evidence upon oath, that there were ample and sufficient directions in Pulvermacher's anticipations to enable people to make Edison filaments?—I do not think I said Edison filaments, but I will not be certain on that point. I know, however, I said there were ample directions in Pulvermacher's specification to enable fine filaments to be made.

And carbonised?—I suppose so.

Would it have been of any use at all for the purpose of breaking down Edison's patent unless it could be carbonised?—Oh, certainly not; but I did not see it carbonised.

I refer you to your evidence in the last case, and quote the following:—"I have myself made filaments by this process, which, I think, are fine enough for any incandescent lamp." Was that true?—Yes, certainly. I made several filaments by Pulvermacher's process, and exhibited them in court.

You mean, then, to represent that Pulvermacher's was an anticipation of Edison's invention?—As a tar putty invention only. The difference was in the quantity of pitch. There was more pitch in Pulvermacher than in Edison.

And you endeavoured to get a decision that Pulvermacher anticipated Edison?—I did not care anything about the decision, I gave my opinion when asked.

Will you tell me what information anybody in 1879 going to make a filament to be carbonised according to Pulvermacher had at his disposal which was not open to a man going to carbonise in 1879 after Edison?—Of course it was all open at the time of Edison, and it was open at the time of Pulvermacher, which preceded.

Did you mean the judge to understand that the man who came to carbonise with the directions open to him could not carbonise a filament?—No; I suppose I did not. I do not know that the point was raised at all at that time.

You were representing to the Court that with the then existing knowledge prior to 1879 of Edison's patent a man could carbonise a filament. What do you mean by swearing to-day that there is not sufficient direction to carbonise a filament according to Edison?—You are putting things to me which I do not think fairly apply to me. I do not think I said at that time there were sufficient directions.

Did you mean the Court to understand, when you were endeavouring to break down Edison's patent, that the directions previously were sufficient to enable people to carbonise, or insufficient?—I do not remember anything on that point specially. I never carbonised at that time, or saw carbonised, one of those filaments.

Pulvermacher's description was of an arc lamp?—Yes.

That arc lamp was composed of a core of carbon, and spiral of carbon surrounding it?—There were two things entering into its composition.

And in between a non-conducting material to prevent continuity of contact?—Yes.

The Court adjourned at four o'clock.

Digitized by Google

THURSDAY, MAY 3.

The cross-examination of Prof. FRANKLAND was continued by the ATTORNEY-GENERAL as follows :

You had not finished telling us about Deprez's experiments ?—In these experiments of Deprez when the temperature was carried to an extreme limit soft graphite—*i.e.*, the crystalline form of carbon—is formed, marks upon the the paper, and is soft and friable. When, however, a more moderate temperature is employed, and the pencil of carbon is immersed, graphite is not formed, but carbon from the carburetted hydrogen is deposited within the pores and on the surface of the pencil, rendering the pencil smooth, and of a bluish-grey, and increasing its size. Further, the pencil becomes denser, harder, bright, and very solid, and Deprez informs us that this is the result of the deposit.

Re-examined by Mr. FINLAY : Deprez describes the coupling up of 600 cells of Bunsen's battery. He first of all says he sometimes arranged the 600 Bunsen elements in one series. That arrangement would give a very high electromotive force, which would impel a very heavy current through such an obstacle as a pencil of charcoal, and would consequently heat that pencil to a very high temperature. Then he describes other experiments in which these cells were coupled in six series of 100 cells in each series. This would reduce the electromotive force of the whole battery to one-sixth of what it was previously, and consequently the temperature of the pencil in proportion.

So far as your own experience of these Pulvermacher filaments extended, are there any points of difference you can direct attention to between them and Edison's putty tar filaments ?—Yes, there are two or three differences. Although the filaments are made of the same materials, the proportions of these materials are different. Edison makes his tar filaments with lampblack and tar, the tar containing certain hydrocarbons and pitch, whilst Pulvermacher describes a mixture of charcoal, tar, and pitch, consequently there would be a larger proportion of pitch.

Were these Pulvermacher filaments made by rolling or forcing through a die ?—They were made by forcing through a die.

You spoke of the lamp you got at the Paris Exhibition from Mr. Sprague, are there sufficient descriptions in Edison's patent for making such a lamp as that ?—Certainly not.

Mr. JUSTICE KAY : In what respect ?—In the first place, there are no directions by which a filament of such very fine texture can be carbonised. Secondly, the workman is directed to make a totally different filament than that which was exhibited ; he is directed to make a filament of great mass, in order that the temperature may increase and diminish gradually by alterations of the current, and he is to get this, as a rule, by winding the filament into the form of a close spiral, which shall have a very small radiated surface in proportion to its mass. He gets this mass either by coiling the filament in a very close coil, or by increasing the size of it, and making it porous. The exhibited lamp shows neither of these peculiarities ; it exhibits in relation to its mass a very extensive surface of radiation, and its mass is very small. In the third place, the filament is attached to the wires by a process not mentioned in Edison's specification.

Dr. TIDY, examined by Mr. FINLAY, said : I am Professor of Chemistry at the London Hospital, and Official Anylist to the Home Office. I have for some time past paid attention to the subject of electric lighting by incandescence. With reference to the process of Edison I have endeavoured to make filaments as described in his specification, with the exception of coiling round copper. I regarded the materials to be used as coming under two heads—1st class : wood, paper, and cotton thread ; 2nd class : tar and putty. As regards the first-class, I attempted to carbonise in a crucible as small as possible without any packing, the top fastened on with Stourbridge clay, and they all disappeared except a little ash. I put in nearly fifty, but the crucible was not very full. I then tried the ordinary method of using powdered carbon, and succeeded. Thirdly, I used sand, as suggested by Sir Frederick Bramwell, and again the filaments were burned up. In November, 1879, an ordinary intelligent workman would, in my judgment, most certainly not have understood the packing with carbon was wanted. The process of carbonisation at that time in use was that of carbonising wood for gunpowder manufacture. Skill in that process of carbonisation would not enable a workman to carbonise filaments successfully, because in the case of carbonising wood for gunpowder a certain loss was of no consequence. I was particularly struck in 1881 or 1882, when I first saw the process of carbonising filaments, shown me by Mr. Crookes, with the method of carbonising with the use of carbon. I tried the making of tar putty filaments ; the difficulty in making them was in the proper consistency. I adopted Edison's process precisely, igniting the lampblack first, mixing the ignited lampblack with the tar. Edison gives no directions as to the proportion. If you use too little tar the thing comes to pieces with the greatest ease long before you get what may be called a fine wire. If you use too much tar the thing runs, so that you cannot do anything with it. After a great many trials I got a wire of the material, I should say about $\frac{1}{25}$th of an inch—quite as small as I could get it—and that was obtained by rolling it on a glass plate, dusting the glass plate with powdered charcoal, and rolling on a spatula. I tried to make a spiral of it, but failed. I saw Mr. Crookes experiment with this and get a spiral. I cannot profess to have the extraordinary manipulative ability of Mr. Crookes ; he is almost unique in that particular. I then carbonised with packing of powdered charcoal, and it fell to pieces as soon as I took it out. The whole thing practically came to nothing. I am aware, in carbonising filaments, how moulds are employed. That is necessary for the process of carbonisation, or, rather, it is necessary to prevent distortion during carbonisation. I did not know the necessity for moulds myself in 1879—indeed, not till three months ago. I did not employ such moulds. I was following Edison. By the absence of such moulds the filaments were all kinds of shapes when I took them out. I should say they would not be useful commercially for making electric lamps. I never got a filament. I could have wound round copper. I tried the effect of joining the platinum and the filament before carbonisation. The effect was that the platinum was rendered more porous and a carbide formed. That is a reaction between the carbon and platinum, with which at high temperature I was perfectly familiar. I should judge that would have some effect on the platinum as to its suitability for a lamp. I tried the use of powdered camphor and oxide of zinc as suggested in Edison, with the result that it rendered the tar putty filament even more difficult to manage; it was not only more difficult to work to start with, but it was even more friable than the others, as I should expect. I never got a filament a quarter of an inch long, when I used those substances, to last after carbonisation. I ascribe that to the reducing power of the carbon on the oxide of zinc and the volatility of the metal. If the oxide of zinc was not reduced in the carbonising furnace, it was certain to be reduced in the lamp. I saw experiments by Mr. Crookes with non-conducting non-carbonisable substances, and quite agree with what he said about them. I have never known on the market for commercial purposes any lamp made under Edison 4,576. I could not even now make a practical lamp from Edison's description. As to Edison's second claim, assuming Swan's lamp, which I have seen, to have been made previous to that date, it combines all four details mentioned in that claim. I have seen the list of non conducting non-carbonisable substances, and in my judgment it embraces the substances which would be suggested by what is stated in Edison's.

Cross-examined by Mr. ASTON : My knowledge of the subject began about 1882. Prior to that time all I knew about carbonising was in connection with gunpowder. I had a good notion, however, what would happen to a thin filament of carbon put in a crucible and subjected to a high heat. I have known Sidot's process for some years. I should not think anybody who knew about Sidot would know about packing in charcoal. Referred to page 18 of Sidot and asked—Assuming that was known at the time, would it have guided an electrician workman to use packing ?

WITNESS : So far as that is stated there it would. The object of my experiments was to test Edison's directions pure and simple, and to test the method of doing it with the knowledge we have at the present day. I did get a thread the $\frac{1}{25}$th of an inch ; that was the smallest diameter. They were always breaking up or running off. Possibly differences of temperature would make the filaments less friable. I tried carbonising the filaments in sand, and utterly failed, getting a little ash only. According to the results I obtained a filament carbonised in sand would be destroyed by the oxygen in the air attacking the filament. That would be the same whether with bamboo, thread, or other substances. Shown a specimen, and asked if he believed it was a filament carbonised in sand.

Witness said he would ask all the details of the experiment.

Would you believe it ?—If you told me I would believe it (laughter).

Mr. JUSTICE KAY : I suppose you would want to know something about the nature of the filament.

Witness : I should like to know so many things (laughter).

Cross-examination continued : I know nothing about the means that could be employed for preventing distortion of the threads until three or four months ago. The filaments I obtained were all distorted more or less.

Is it not true that in all these cases, where you are obtaining experiments of this kind in order to obtain the most beneficial results, an experienced operator would very often be able to moderate imperfect results by altering your operations ?—No doubt.

Mr. JUSTICE KAY : That only means that if an experienced operator like Dr. Tidy went on operating long enough he might produce a result.

Prof. SILVANUS THOMPSON, examined by Mr. FINLAY, said : I am a member of the Society of Telegraph-Engineers, and of various physical societies here and abroad. I have for a good many years devoted attention to electricity and electric lighting by incandescence. I first met Mr. Stearn at Liverpool in 1877 at a meeting of the British Association. He exhibited the improved Sprengel pump, and I saw it. I visited his house at Rockferry in 1880. There were electric lamps in that house of which the globe was made wholly of glass, through which the leading wires passed and were sealed, and containing a thin conductor consisting of a carbon wire, and which had been exhausted. These were used all over the house for lighting. I was present at the British Association at York in 1881. A picture gallery there was lit up with Mr. Swan's lamps. These lamps were of the same kind in general as I had seen in Mr. Stearns's house. In 1881 I went to the Paris Exhibition, and saw the Swan lamps exhibited there. They were lamps of the same kind as the the others I have spoken of. I first saw an Edison lamp at the Paris Exhibition in 1881. I examined them as well as could be done without taking them into my hands, and afterwards I had an opportunity of examining closely lamps of exactly the same type. They were lamps which should come within the second claim, but with many subsequent improvements in their details upon the lamp described in the specification 4,576. [Shown FF 1. The lamp put in by Dr. Frankland, and which was similar to the lamps of which he spoke.]

Witness continued : The carbon conductor is more in accordance with Edison's latest specification, 578 of 1880, the paragraph beginning page 3, line 31, of the specification. As a second point, so far as I can judge, this conductor has been held in shape during carbonisation in the manner claimed in the subsequent specification, No. 3,765 of 1880, book 3, page 63, line 46. Third, the carbon conductor has its ends left apart, in the manner described in specification 1,918 of 1881.

The Court then rose for luncheon.

On the Court resuming, Professor SILVANUS THOMPSON, examined by Mr FINLAY, continued as follows : The clamp which holds the end of the carbon conductor is flattened in the manner described in the subsequent specification 2,492 of 1881. The joint so made has been electroplated in the manner prescribed in the subsequent specification 768, of 1881. Between the end of the carbon conductor and the platinum wire which is fused to the glass. there has been joined in a separate piece of

Digitized by Google

wire, not of platinum, in the manner described in specification, 4,174, of 1881. The bulb has not been blown over, the rest of the lamp as described in Edison's specification, but has been separately made in accordance with specification 2,492 of 1881. The platinum wires that pass through the glass are connected to the terminals of another metal in the manner described in specification 2,492, of 1881. The lamp has been provided at its neck with collar connections in the manner described in specification 1,802, of 1881. This lamp has been heated during the process of exhaustion in the manner described in specification 562 of 1881. There are no other points occur to me at the moment.

By Mr. JUSTICE KAY: The intermediate wire is copper. The object of putting it in is for cheapness in economising platinum, and because it is easier to electroplate copper upon copper than to electroplate copper upon platinum. This connection is made after carbonisation.

By Mr. FINLAY: The exhibition of Edison's lamps at Paris compared very indifferently indeed with Swan's lamps. The hall was lit with a number of lamps—I don't think there were as many as forty—and the thing that struck me when I went into that room was that the light was very red, the lamps were bright red hot. I thought it a miserable exhibition in comparison with Swan's. Compared with the lamps I saw in Mr. Stearn's house, the lamps were larger in themselves, but were not run at such a degree of incandescence, they were more nearly red hot. The lamps were very effective in Mr. Stearn's house, and also at the *conversazione* at St. George's Hall, Liverpool. In November, 1879, electricians would be aware of the advantages of high resistance, so far as there are any advantages in it, but there are no advantages *per se*. The advantage of high resistance is entirely external to the lamp itself. It enables you, in the case where you wish, to distribute electric energy to a distance, whether for lighting or for motive purposes, to economise the cost of the conducting mains. I am acquainted with the carbons manufactured by M. Carré, some specimens of which I exhibit. I have not seen the process of manufacture of M. Carré's carbons, and know it only in general. In specification 792 of 1881 Mr. Edison refers to the commercial use of low-resistance lamps. I saw two safety lamps at Mr. Swan's, such as were exhibited at the British Association meeting at Birmingham; the lamps were of exactly the same shape, they burned perfectly well. I saw them run; they worked beautifully. I have given very close and careful attention to Edison's specification in all its features.

In your opinion could a workman of ordinary intelligence and skill, in November, 1879, have made an incandescent lamp from this description?—From this specification; certainly not.

Examination continued: In the first place the general tenor of the specification would mislead him as to the lamp that would be serviceable, and in the second place the lamp is never described. I have looked carefully through the whole of the processes described in the specification, and in my opinion they are insufficient. I have been familiar with the electric lamps that have been on the market for the last twelve or fifteen years and have never known one made under this specification. I do not find in this specification any description of what is intended by a filament. I always looked upon it as a new use of an old word to save long phraseology. I have examined most of the exhibits put in in the course of this case.

The Court adjourned till Monday next at 10.30.

MEETINGS OF SCIENTIFIC SOCIETIES.

(TO-NIGHT) FRIDAY, May 4th.

SOCIETY OF MECHANICAL ENGINEERS.

7:30 p.m. Continuation of meeting at the Institution of Civil Engineers. Reading of Papers and discussion.

ROYAL INSTITUTION.

9 p.m. Lecture, "The Invincible Armada." By Prof. J. K. LAUGHTON.

SOCIETY OF ARTS.

8 p.m. Indian Section. "The Injurious Effects of Canal Irrigation on the Health of the Population of the Punjab." By Surgeon-General H. W. BELLEW, C.S.I., C.I.E. Sir JOSEPH FAYRER K.C.S.I., will preside.

SATURDAY, May 5th.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Later Works of Richard Wagner" (4). By Mr. C. ARMBRUSTER.

MONDAY, May 7th.

SOCIETY OF ARTS.

6 p.m. Cantor Lecture VI. "The Decoration and Illustration of Books" (2). By Mr. WALTER CRANE.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at Westminster Hall. Paper on "Filtration by Machinery." By Mr. E. PERRETT A.M.I.C.E.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

TUESDAY, May 8th.

SOCIETY OF ARTS.

8 p.m. Applied Art Section. "The Decorative Use of Colour. By Mr. J. D. GRACE. Mr. E. C. ROBINS, F.S.A. will preside.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Plant in the War of Nature" (2). By Mr. W. GARDINER.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The Distribution of Hydraulic Power in London." By Mr. E. B. ELLINGTON, M.Inst.C.E. Papers to be read with a view to discussion: "The Tay Viaduct, Dundee." By Mr. CRAWFORD BARLOW, M.Inst.C.E. "The Construction of the Tay Viaduct, Dundee." By Mr. W. INGLIS, Assoc.M.Inst.C.E.

ENGINEERING SOCIETY (King's College).

4:15 p.m. Paper on "The Forth Bridge." By Mr. GASK.

WEDNESDAY, May 9th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Locks and Safes." By Mr. S. CHATWOOD.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

7 p.m. General Meeting for presentation of Report, Election of Council, &c.

IRON AND STEEL INSTITUTE.
(At the Institute of Civil Engineers.)

9:45 a.m. Meeting of the Council.

10:30 a.m. General Meeting. Scrutineers will be appointed for the examination of the voting papers. Presentation of the Bessemer Gold Medal for 1388 by Sir Henry Bessemer, F.R.S., in the name of the Council, to Mr. D. Adamson, President of the Institute. A selection of Papers will be read and discussed.

THURSDAY, May 10th.

IRON AND STEEL INSTITUTE.
(At the Institute of Civil Engineers.)

10:15 a.m. Meeting of Council.

10:30 a.m. General Meeting of Members. List of Papers.—Adjourned Papers: 1. "On the Mutual Action of Sulphur and Silicon on Iron at High Temperatures." By Mr. T. TURNER, Mason Science College, Birmingham. 2. "On the Use of Water-gas for Metallurgical Purposes." By Mr. A. WILSON, Stafford. 3. "On the Imperfection in Mild Steel Plates, considered Chemically." By Mr. H. ECCLES, Port Talbot. 4. "On the Mechanical Apparatus for Continuous Moulding at the Works of M. Godin, Guise." By Mr. JAMES JOHNSTON, Manchester. 5. "On the Effect of Arsenic on Mild Steel." By Mr. F. W. HARBORD and Mr. A. E. TUCKER, Bilston. 6. "On the Manufacture of Ordnance at Trubia." By Major CUBILLO, Trubia. New Papers:—7. "On the Melting of Wrought Iron or Steel Scrap, mixed with Ferro-silicon, in Cupola Furnaces." By M. F. GAUTIER, Paris. 8. "On the Behaviour of Arsenic in Ores and Metals during Smelting and Purification Processes." By Mr. JOHN PATTINSON, Newcastle-upon-Tyne, and Mr. J. E. STEAD, Middlesbrough. 9. "On a New Instrument for the Measurement of Colour, more Especially as Applied to the Estimation of Carbon in Steel." By Mr. H. LE NEVE FOSTER, West Hartlepool. The Council have still to determine the order in which the Papers shall be read.

SOCIETY OF TELEGRAPH-ENGINEERS.

8 p.m. Meeting at the Institution of Civil Engineers. Paper, "On the Risks of Fire Incidental to Electric Lighting." By Mr. W. H. PREECE, F.R.S., Past President.

ROYAL INSTITUTION.

3 p.m. Lecture, "The Chemical Arts" (5). By Prof. DEWAR.

SOCIETY OF ARTS.

2 p.m. Conference on Canals and Inland Navigation.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of April was 4,684, estimated to produce £3,700, against 3,823 messages, producing £2,964 in the corresponding month of last year. The traffic receipts for the month of Jaunary, estimated at £3,300, realised £3,355.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of April, 1888, amounted to £51,582, and to £43,136 in the corresponding period of 1887.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of April, 1888, amounted to £37,331, and to £35,955 in the corresponding period of 1887. Increase £1.376.

SOUTH OF ENGLAND TELEPHONE COMPANY (LIMITED).—The directors of this company yesterday declared a dividend of 6 per cent. per annum on the preference shares of the company for the half-year ending 30th April, 1888.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the month ending 30th April amounted to £4,325.

"The Electrician" in America.

'THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.*
It has the largest circulation of any English Electrical paper, and circulates all over the World.
Particulars relating to Advertisements will be promptly forwarded on application to this office.
Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

VOLUME XX. OF "THE ELECTRICIAN"
Will shortly be ready. Bound in cloth, price Ten Shillings and Sixpence. Also Cases for Binding, price Two Shillings.

Application should be made to "The Publisher."

LIGHTSHIPS AND THE TELEGRAPH.

In the House of Lords last Friday evening the Earl of MORLEY directed attention to the question of electrical communication with lightships, reported upon by a Committee of the Board of Trade several months ago, and now being taken up again by the Associated Chambers of Commerce. Lord MORLEY himself does not go so far as some of the Chambers of Commerce, who are urging the connection of all the lighthouses and lightships with the Post Office inland telegraph system; and for reasons which were fully stated in these pages on the publication of the Committee's Report last September, that scheme cannot be entertained unless the Chambers of Commerce are prepared to take all the risks. The business derived from these sources would not be likely to repay the Post Office Telegraph Department for its expenditure in laying and maintaining the necessary cables. It rests, therefore, with the trades concerned —chiefly the shipping trade—to determine whether the commercial advantages to be gained, added to the revenue to be derived from the signalling of shipping intelligence, would warrant the outlay. On this point they appear not yet to have made up their minds, and Lord MORLEY is not able to assist them. For his own part he would have the electrical communication established round the coast if only for the purpose of saving life at sea; and he adduced some fresh evidence to show that the means suggested would be far more effectual to this end than the testimony given before the Committee seemed to indicate. It will be remembered that the Board of Trade's inquiry was confined to the Thames and its approaches, and directed mainly to the experiment at the "Sunk" lightship, which had been electrically connected with Walton-on-the-Naze in the previous year. It is now pointed out that this is by no means the most dangerous part of the coast, nor the one where the

Digitized by Google

service of the telegraph or the telephone would be of the greatest utility.

The only reason discoverable for the selection of this particular area for the experiment was, not because of its special fitness, but because of the existence of a special fund, called the "Mercantile Marine Fund," from which the expenses could be defrayed. This fund happens to be applicable only to what is technically included in the designation "Thames," and of the twenty reasons or thereabouts which the Earl of ONSLOW assigned for not yet extending to other lightships the advantage of telegraphic connection which has been enjoyed by the "Sunk" since March, 1886, the one that had evidently most weight with him was that the fund referred to is exhausted. Such is the poverty to which this nation has been reduced that we would fain resort to the Mercantile Marine Fund if it could be legally diverted from its legitimate purpose, and if, indeed, any of that fund remained. But it is already exhausted, and, like the memorable excuse for not firing a Royal salute, this one of having no money to spend is as good as that of having no ammunition to fire. The fund at its best is a very small one, and has already had to be assisted by considerable loans. How, then, is it possible to extend these experiments, however desirable their object may be, when all the money is spent?

As to the remaining and superfluous reasons for doing nothing assigned by his lordship. most of them were erroneous, and some of them were even foolish. The experiment at the "Sunk" lightship, so far from being comparatively unsuccessful, has decisively proved the practicability of permanently attaching a submarine cable to a floating lightship which, though moored, is shifting. If this particular telegraph service has not yet forestalled the rocket signals for the several cases of distress in its vicinity occurring since the cable was laid, the fact speaks well for the clearness of the atmosphere on those occasions, but detracts nothing from the potential value of electrical signalling for foul weather. And on some parts of our shores, notably on the Irish coast, the lightships, and consequently most of the passing vessels, are cut off from the shore at night by impenetrable fog. This, at all events, is very generally the case; and it would not be difficult to mention many other points of danger where direct and instantaneous communication with the shore would frequently save precious time, which in this relation means human life, by indicating when and where succour is needed. There may be good and sufficient reasons for not extending the "Sunk" lightship experiment all round the coast indiscriminately; but to allege as a reason for not extending it anywhere the impecuniosity of the Mercantile Marine Fund seems to us utterly unworthy of a country whose shipping trade and whose national resources are equalled by no other country in the whole world.

Against utilising these lightships as signalling stations for the purposes of commerce it has been urged that their security would be jeopardised by the approach of the trading vessels desirous of sending messages. We owe this argument to the Board under whose care all the lighting of the coast is placed; and from the point of view of the caretakers it is properly put forward. But when fairly examined from the users' point of view the objection cannot be taken very seriously. Lightships, of course, are beacons of warning, not places of converse; but their character would not be altered in the former respect, it seems to us, if they served on occasion the purpose of the latter. In fair weather they could be approached near enough to be communicated with; and in bad weather we may trust the captains to run no unnecessary risks. It may be admitted, however, that some uncertainty and conflict of opinion exist as regards the two objects for which these coast telegraphs have been generally advocated—one as an aid to the lifeboat service, the other as a purveyor of shipping intelligence. The utility of both are questioned from two opposite quarters; but probably because neither wishes to bear the whole expense of the undertaking. One other object would be served, not mentioned in the discussion on Lord MORLEY'S motion, namely, that of supplementing the coast defences of the nation. Possibly these three interests may some day come to an understanding mutually advantageous and helpful, so that the cost shall be divided among them. Their destructive criticisms would then cease, and we should expect to have a complete system of coast telegraphs in full connection with the inland system.

THE NEW CABLE STEAMSHIP "AMBER."

The new telegraph cable steamer "Amber," the fifth vessel of its kind for the Eastern Telegraph Company (Limited), has been built and engined by Messrs. Robert Napier and Sons, of Govan, Glasgow. She left Gravesend on Saturday last for Cadiz, and is now employed on some cable work there.

The "Amber" is the smallest vessel of the Company's fleet, but owing to the engines having been placed in the after part of the ship, thus leaving available the best part of the ship for cable tanks, saloon accomodation, berths for officers and crew, the ship is rendered thoroughly efficient for any description of cable repairs required.

The dimensions of the steamer are as follows:—Length 210ft., breadth 31ft., depth 24ft., her builder's tonnage being 978 tons, net register tonnage 557 tons.

Being built for an awning deck (class 101 A 1 at Lloyd's special) she has an uninterrupted deck fore and aft, with head and stern sheaves, giving every facility for the work in which she is to be engaged.

The vessel is wholly built of steel, and all the most modern appliances have been adopted, including steam steering-gear; the engines are triple expansion, the cylinders having a diameter of 19, 30, 46, by 36 stroke, pressure 170lbs., driving the ship at a speed of 13 knots on an easy consumption of coal.

The cable gear is the design of Messrs. Latimer Clark, Muirhead and Co. (Limited) on the tandem principle, driven by two separate engines, which can be united together and exert either their full power, if found necessary, on either of the drums, or can be separately used on one or the other drum independently.

The electric lighting and search lamp is by Messrs. Johnson and Phillips, of Charlton, Kent.

The saloon is amidships and is very tastefully finished, being enamelled white and gold.

The wood-cut on the next page will give a general idea of this ship, which is beautifully lined. It is the third ship of its kind which has been illustrated in these pages. One was the "Magneta," a full description of which we gave in our issue of 3rd January, 1885; the other was the "Electra," given on the 7th of the month following, the cable gearing of both of which vessels was manufactured by Messrs. Johnson and Phillips.

The dimensions of the "Amber" are rather less than those of the two vessels just named, each of which were 230ft. in length and 32ft. in beam, their (builder's) tonnage being 1,096 tons. The "Amber's" depth, however, is the same as her predecessors'.

It will be remembered that the "Magneta" was lost, with all hands, about three years ago; and the new steamship "Amber" has been designed to take her place. The "Amber" is fitted with all the latest and most approved appliances for cable laying and cable repairing, and is, it may be said, the outcome of the varied and wide experience which the owners of these vessels have gained in their important operations.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

CENTRAL STATION LIGHTING.—TRANSFORMERS v. ACCUMULATORS.

On Thursday, April 26th, the Society met at the Institute of Civil Engineers to resume the discussion on Mr. Crompton's Paper, the President (Mr. E. Graves) in the chair.

(*Resumed Discussion on Mr. Crompton's Paper, from page 698.*)

The PRESIDENT announced that Mr. Crompton could not be present until the 17th May, and they proposed to close the discussion that evening and hear Mr. Crompton's reply at their meeting on the 17th May.

Mr. ESSON then resumed the discussion. He said Mr. Crompton's Paper ought to be a valuable one, inasmuch as it professed to deal with the facts and figures contained in actual working; he could not help thinking at the beginning that it would be much more valuable if Mr. Crompton had confined himself solely to the figures obtained at Vienna, not to figures extracted from a hypothetical case, which he had not yet carried out. It was of great interest to know precisely the return which was obtained from accumulators, and as far as he knew those results were not higher than 60 to 61 per cent. With respect to the total working expenses, he thought there might be very little to choose between the transformer and the secondary batteries; but until they had the actual figures obtained from an alternating transformer system all their estimates must be very much of the nature of a speculation. He wished that some gentlemen who were specially interested in alternating currents would show their coal bills—that is to say, if they had them with them (applause). As regarded the reliability, he did not think that there was, on the whole, much to choose between the two systems. As far as the generating station was concerned, he placed as much faith upon the alternating-current system as upon the accumulator system. But when they came to the question of mains they had a somewhat different subject. When they came to the general system of distribution, where they had very complicated conductors, he should view with distrust any scheme which placed a network underground at a potential of 2,000 volts. Of course they had very little experience of the behaviour of conductors underground when fed with such high potentials, but such experience as they had certainly tended to make them distrust the effect which was said to have been produced. It seemed that if they were to have safety they must have a few large transformers to distribute the current at a few hundred volts; and when they did that they came to much the same thing as was the case with Mr. Crompton. The transformer stations, and the cost of distributing mains on both sides, cancelled out, and the only difference was the cost of charging mains for 500 or 2,000 volts.

Prof. FORBES, who was received with much applause, said: I think that the Paper which has given rise to this discussion is of a character which ought not generally to be read before the Society. I think it is unfortunate that a Paper should have been given to us on what is purely a hypothetical case. I think we ought generally to deal in our Papers with accomplished facts as much as possible, and in the case of installations that we should have the actual results from practice; and I consider that the discussion which this Paper has given rise to is probably the more valuable part of it, although the discussion has extended itself beyond the scope of the Paper, and has become a general discussion of the distribution of electricity. I am very sorry that Mr. Crompton is not present, because there are several things which I should have particularly wished him to have heard, and especially these introductory remarks of mine. I think it is extremely unfortunate that he did not give us a Paper upon the two installations which he tells us have been so successfully worked, and which would bear out the results of the Paper itself, viz., the Vienna installation, and another one which he has at Kensington. He would have been able to give us some information about the action of the accumulators which have been used in those two places, about the amount of current that was put into the accumulator and taken out, and a great deal of information which would have been very valuable to us. We want some detailed information about the Howell accumulator. It is all very well for him to say to us that we may see the Howell accumulators, that we have every facility of examining them, and of going to Kensington any evening we please and seeing them working. I, for one, have not been able to determine the value of an accumulator by seeing it simply in a central station and examining it at work (applause). Mr. Crompton states at the beginning of his Paper the object for which he has written it. It is to support an assertion which he had made on a previous occasion, to the effect that "I believed the distribution of electricity by transformers offered no special advantages over other methods." And then, instead of discussing the various methods which might be used in preference to transformers, he selects one (as it happens, the least advantageous one he could have selected), that of an accumulator. In this particular case he has not proved the assertion that he made before, that transformers have no special advantages over other methods, because he has taken a single case, a case of a small station of 10,000 lights, with 2,000 yards of charging mains. I say even if he proved his case with that, where the transformer was not specially eligible, he would not have proved the case where transformers are specially useful. Now, in the special case which he has taken, I think it would have been much more natural that he should have taken some other system of distribution. There are numerous other systems which he might have adopted and gone into, and there is no doubt in my mind what system would have been found the most economical, and which would have been far cheaper than the transformers and than the accumulators, and that is the system Mr. Stanley has lately completed in America, and which I find has been noticed in this Society in Mr. Mackenzie's Paper on transformers. As an example of the cost of different systems of distribution, I may mention that a couple of years ago, after I had published my theoretical work on the distribution of electricity, I took a special district of London, the club district of Pall Mall and St. James's, and got information from the secretaries of those clubs as to the length of hours of lighting in different rooms, and the number of lights in each room, and other data, and I then devoted a considerable length of time, with the assistance of Mr W. H. Snell, who was then in my office, taking out the cost of the different systems. I simply mention the results:—The simple parallel system costs per candle-power per annum 2s.; the three-wire system, 1s. 10½d.; the multiple series system, 1s. 10d.; the same system when complying with Board of Trade requirements, 2s.; Bernstein's series system, 1s. 10¾d.; secondary generators, 1s. 11½d.; secondary batteries, 2s. 4d. The price of secondary generators has been reduced since that date.

Mr. Crompton gains very little by putting his batteries in series. He gains in the cost of the 2,000 yards of charging main, but nothing on the cost of the 20,000 yards of distributing main. This small gain is not an equivalent for the inconvenience of introducing 480 volts into houses. Our president has said that our time is limited, and I do not think that it is worth while devoting very much time to the figures which occur in Mr. Crompton's Paper.

The chief points in his Paper are the two tables—the cost of installation and the cost of maintenance, and I will say a few words on these. In the first place, in Table A, we find that there are 600 kilowatts required as a maximum. Now, from the remarks which have been made by gentlemen here, I fancy that it may be of some interest if I illustrate my remarks on the Paper by the practice in America, which I have had very considerable opportunities of examining in all its details within the last few months. Now, it is found most positively that the return of the transformer system, which is used there by Mr. Westinghouse, enables us to get from each horse-power 600 watts in the lamp for the indicated horse-power (applause). Mr. Crompton for a 600-kilowatts station has demanded 1,450 horse-power instead of 1,000 horse-power—that is to say, he has added as a reserve 50 per cent. of what is actually required at a maximum. We also find generating station buildings, chimney shaft, water tanks and general fittings £11,000, which he has apportioned to his 1,450 horse-power, on the alternating-current system, while to the accumulator system he has apportioned only £8,000. A reduction will take place there also. The cost of dynamos and exciters is perfectly correct. In accordance with American figures, the price which Mr. Crompton has given us would approximately include everything in the station, including the station switches, resistance boxes, voltmeters, ampere meters, lightning arrester, ground detector, compensators and synchronisers, with spare armature ball bearings and brushes. These are all included in that figure. The price of transformers is given by Mr. Crompton at £7,500 instead of £4,000. The mains are the point in which Mr. Crompton makes the greatest error. He has failed to appreciate the value of the transformer system in saving the cost of mains. In most systems the mains being massive must go underground. But with the maximum current of 300 amperes required in this station on the converter system, they ought to be overhead wires, which reduces the cost enormously. If we were dealing with a station of 100,000 lights, Mr. Crompton will see from his table that the cost of mains does then become almost exactly proportional to the weight of copper, and here the converter system again maintains its superiority. I therefore reduce Mr. Crompton's estimate for mains to £6,000. Having made all these corrections to the estimate for the converter system, it is reduced to £34,140 instead of £57,440. Hence the relative cost of converters and accumulators in the unfavourable case chosen by Mr. Crompton is £34,140 to £59,652.

Having pointed out the source of error in this estimate when dealing with the alternating-current system, I now point out one source of error in connection with the accumulator system which is sufficient to throw doubts upon the accuracy of these results. I speak of the efficiency of the accumulators. You will find that he tells us near the end of the Paper what is the efficiency of the whole system; that is to say, the combined efficiency of the conductors and the accumulators, including both of them. He says:—"For the output of 2,100 units it will be sufficient to work the generating plant for about five hours at approximately its greatest rate of efficiency. I have had ample experience with this class of plant, and know that we can in actual practice produce the E.H.P. at the terminals of the dynamo with the expenditure of 3½lb. of coal." Good—granted. Then, "taking the maximum loss in the accumulators, the efficiency of the system—that is, the E.H.P. at the lamps divided by E.H.P. at the terminals of the dynamo—will not be less than 80 per cent." "Therefore," he goes on to say, "we may say that each unit at the lamps can be produced for 5·75lb." Three and a-half pounds of coal for the work given out at the terminals of the dynamos, and only 20 per cent. on this for the loss in conductors and accumulators. Now, he has told us in his Paper that in his conductors, while admitting the loss of 10 per cent. in his charging mains and 4 per cent in his distributing mains, that comes to 14 per cent.; as a matter of fact, I have worked it out, and I find that his charging mains have a loss of 12 per cent., instead of 10 per cent. That would make 16 per cent. altogether, but I do not know how the distributing mains are worked. That is, 16 per cent. out of the 20 per cent. is due to the charging mains, and 4 per cent. loss of efficiency in the accumulators during the five hours, when he says the generating plant is working at its greatest output. That is to say, he employs accumulators which are giving an efficiency something like 96 per cent. He tells us the average rate which the accumulators have to be able to

Digitized by Google

discharge. The cells while discharging normally at the rate of 416 amperes are to be able to go on discharging at that rate for five hours, giving a capacity of 2,080 amperes; but while their normal discharge is 416 amperes are to be kept at a rapid discharge at an efficient rate of 1,352 amperes. In his final table of the working of the accumulators, he gives us the depreciation of accumulators, and he puts it down at 15 per cent. as the working of accumulators. We know of no accumulators that will work at that rate of maintenance. I know this, from the experience of Mr. Preece, who told me the other day that in his accumulators, which had been carefully watched, out of 16lbs. of active material there is 1lb. lost in the first year. Now, finally, in his estimate for the cost of these cells he tells us in order to make his system effective he must take a cell which will normally discharge at 416 amperes for 5 hours, which will have a possible rate of discharge of 1,352 amperes, which will give an efficiency of nearly 95 per cent., and which will have a depreciation of only 15 per cent, and that he will get these cells for £40 a piece. Now I have said that it would have been better if Mr. Crompton had given us the results of his own experience with accumulators at Vienna and at Kensington, and I am perfectly certain that the result would have been totally different from that he has claimed here. I am very sorry to find that Mr. Crompton should have made a statement in the first page of his communication to the effect that the experience which has been gained in America and in other places with the alternating-current system does not help us much in our investigation. I say that it would help us infinitely more than any number of Papers he might have laid hands upon. In the few months that I have been studying the system practically in the States I have gained more information, such as is applicable to Mr. Crompton's station, than reading the Papers of all who have written in this country on the subject. I wish to refer to one point before I leave the question of these estimates. Mr. Crompton has stated that a great deal of nonsense has been talked about the cost of conductors in proportion to the cost of copper, and I daresay a great deal of nonsense has been talked. I do not remember particularly, but it is quite possible that there has. But do not let us have any more nonsense on the subject (laughter). Mr. Crompton says that these tables are sufficient to show that we must have considered the cost of repeating the conductors as in any degree proportionally to the cost of copper. I say that in overhead wires you must consider that it is so; and while I would not wish to see overhead wires laid in a really large installation, still in small installations of 10,000 lights I think that they ought to be laid; but what we want to see, at any rate in this country, is a sound installation of a large number of lamps. In most of my observations on the distribution of electricity I have generally dealt with the installation of 100,000 lamps, and that is a likely size for a town with a population of four and a-half millions. Now look at the dimensions of the cables, which he gives in table No. 2. He maintains that the cost of laying them is out of all proportion to the cost of copper, but when you come to 2 5 square inches section and three inches section you will find that the cost of laying has become gradually small—very small—in comparison with the copper, and the total cost is nearly in proportion to the weight of copper. And when you come to cables for 100,000 lights we may take it as absolutely assured that the total cost of cable laid is about proportional to the cost of copper. Here, sir, my criticism of Mr. Crompton's Paper ends. I had thought since the discussion had generally gone to the distribution of electricity that possibly you would like to hear something about the alternating-current system as used in America. I intend to give somewhere or other a full account of that system as used in America; but I had thought some little account might have been interesting here (applause).

Mr. PREECE hoped that Prof. Forbes would give them five minutes of his experiences in America (applause).

Prof. FORBES: I will give you one fact first, which has some bearing on the figures in Mr. Crompton's estimate, and that is the station attendance—the cost of keeping up a station in America. That was the thing that struck me more from a commercial point of view than anything else—the small number of men and the small amount of labour and supervision required for a station. Denver has a capacity for 7,000 lamps. It employs one manager at 150dols. a month, a secretary at 80dols. a month, and an office boy. It has two dynamo attendants at 70dols. each, and two engine attendants, five firemen, and two inspectors, who go over the lines and repair them. That is the total staff for the Denver installation of 7,000 lights. That is a station where coal is used. In several of the stations which I visited—for example, at Pittsburg and Allegheny and East Liberty—coal is not used. Going into the boiler room, you wander about, and the first thing that strikes you is why is nobody here, and you find a moody, melancholy man sitting reading a newspaper, who is attending to the whole of the boilers for a 10,000 plant. The furnaces are fed in this case by the natural gas. Natural gas and the air are let in through pipes controlled by a valve, the valve is controlled by the pressure in the boilers, and the boiler attendant has simply nothing to do. The pressure on the boilers is able absolutely to control the gas and air. The engines of the alternating current have been Westinghouse engines, which although fairly economical in steam, are not very economical; but they give very little trouble. Small engines are always used in central stations—not less than four of them—driving the dynamos by belt direct. The largest engines work up to about 250 horse-power. There can be no doubt that it is a mistake to put down one large engine to do the variable work in a central station. It cannot be economical in coal consumption. Mr. Westinghouse has nearly completed a rotary engine for working his dynamos direct, and he hopes for a high economy from them.

The alternate-current dynamo machines which are used in the States are totally different from what have hitherto obtained as the type of dynamo in this country. I do not know what progress has been made in the last three months, but I presume that the alternating type of dynamos, which were favourites lately, are now given up. Those were armatures such as those of Siemens and Ferranti. The Westinghouse armature has plenty of iron in it. It has been frequently described in this country. It is a drum armature, made of thin iron discs. The wire is wound round strips of wood, which are laid longitudinally on the periphery of the cylinder. The number of poles is 16 in the large machines, and they work at the rate of 1,000 revolutions per minute. The discs forming the armature are punched with six holes to lighten them. Still, the armature is heavier than necessary. The machine is mechanically good, strong, and substantial, with every part machine-made and interchangeable. The heating is very small. The exciting power is 2 per cent. of the total power generated by the machine. There are only three types of machines made—650 lights, 1,300 lights, and 2,600 lights. The resistance of the armature of the large machine is 0·15 ohm. Its weight is about 18,000lb. There is one defect in the machine, namely, the sixteen useless wireless surfaces on the periphery of the armature. One would naturally suppose that these spaces on the armature ought to be filled by iron like Pacinotti teeth; but there are great mechanical difficulties which would increase the cost of manufacture to a great extent. I have suggested (and I believe the suggestion is going to be adopted by the Westinghouse people) that this vacant space should be utilised by making a complete additional set of windings on the unused parts, which will form a separate circuit, and be a quarter of period behind the phase of the other winding and will supply separate feeders. In that way the capacity of the dynamo, though very good in itself, will be increased something like 25 per cent. or 30 per cent. (applause). With regard to alternate-current machines, I should like to throw out a suggestion that the most efficient type of the machine of the future seems likely to me to be a different type to those which have been hitherto adopted. Most of us have been interested in the progress of Mr. Parsons' turbo-electric generator. That engine is made to consume only 39lbs. of steam per horse-power per hour, and it may be improved so as to be an economical engine. The large-sized machine of 300 amperes and 80 volts runs at 8,000 revolutions per minute. I have suggested, first of all to Mr. Parsons, and he has undertaken to act upon the suggestion, that he should take his commutator, and put two rings around it, connected one with one bar of the commutator and the other with the opposite bar, leaving a small space on the commutator to take off a continuous current to feed the field-magnet. Brushes will collect an alternate current from the two rings. Since the speed of revolution is 8,000 revolutions per minute, that means 16,000 alternations per minute, which is exactly the number used by the Westinghouse Company.

One has heard a good deal about converters. I have recently had an opportunity of testing converters at Pittsburg, and I adopted the same method as Prof. Ayrton described—that is, the calorimetric method which was first used by Ruiti. I adopted the form of experiment suggested by Prof. Ayrton, and I made some careful tests, and the most important result which is arrived at is that in his No. 6 converter (which is a 30 light machine), with a half load, I got 95 per cent. (applause). I shall conclude my remarks by just saying one practical word about the manufacture of dynamos and converters at the Westinghouse establishment. There are only a certain number of types made, only three types of dynamos, and only five types of converters; and that is absolutely essential to the success of manufacturing for a large sale, and to supply the public at moderate prices. It was quite sad to me to remember and think of our manufacturers when an order is sent in to them. They are told the number of volts and amperes which the manufacturer has to provide for. It is ridiculous to expect to get economical dynamos in this way. It is only by doing the manufacture on a large scale that we can get things at a cheap rate. To make a single converter at Mr. Westinghouse's factory, about ten different machines have to be employed which are extremely costly to make; but each of these ten machines is able to turn out 50 to 100 of the parts of the converter with which it has to do in the day; and therefore, by having these machines ready to construct always exactly to scale, Mr. Westinghouse is able to produce them at an extremely low figure. This is a successful plan from the manufacturer's point of view, which I should urge on the manufacturers of this country. There is an important fact from the user's point of view, that the parts of such machines are all interchangeable and to scale. If your dynamo armature gives out, you simply telegraph, for example, for a No. 3, and it comes by the next train, and so on with every other part that is required. I have a few specimens of some of the smaller parts of the Westinghouse distribution apparatus on the table—switches and cut-outs and things which may be interesting to some.*

Mr. J. E. H. GORDON: After we have listened to Prof Forbes's most interesting speech we feel that our friend Mr. Crompton, if he were here, ought to feel himself very much pulverised; but no doubt if he were here he would have a different view. Much has been said, not only by Prof. Forbes, but by other speakers, about the disadvantage of not being able to obtain any accurate figures about accumulators, and perhaps a few notes which I have of results from actual contracts may clear up some of these points. Before going to these notes, however, I would like to say a word about the diagrams that Mr. Crompton showed last week, and in which I feel some personal interest, because I was, I think, the first to show them to the Society. There is one load diagram for London and two for America, and I want you to see how extraordinarily accurate they are, and this is shown by the trifling difference between them. In the London diagram the peak comes at seven o'clock, at Boston it is a little after half-past five, and at Cincinnati it is a quarter to six, which quite illustrates the fact that the average time for dinner in America is 1½ hour earlier than in London; thus there is a

* See illustrations on page 752.

Digitized by Google

coincidence which goes a good way to show that the diagrams are most accurate. Really the stars in their courses seem to be invoked by Prof. Forbes to fight against the accumulator system, for not only has it its inherent defects, but overhead wires are to be laid for the transformer system alone, which I believe are not going to be laid for anything else. We are hoping to get rid of overhouse wires, but they are stated to be necessary for the success of the transformer system on a large scale. Then we are to have a Government which is to allow us to use 2,000 volts alternating, but only 400 volts direct. Then we are to omit all spare gear in order to keep the capital cost of the transformer system down. I have had a little experience in working without spare gear. At Paddington we have 50 per cent. spare gear; but we had a law suit, and had to make some alterations in the machines one by one, and for five months we had no spare gear. Nothing happened, but there was a great source of indirect expense due to what I might call the depreciation rate of the engineers, which gets very high indeed when there is no spare gear. In fact, I think that if we were to go on much without spare gear, as the industry develops the depreciation of engineers will go on at such a rate that we shall soon have no engineers at all. I have no interest whatever in any battery or other electrical apparatus at this moment, I only go to the best maker for the articles I contract to put down, and I can speak on the subject, perhaps, in a way that Mr. Crompton could not. I will give you some details of the Howell cells—details taken from a contract signed between Mr. Crompton and ourselves, dated December 22, 1887. The contract is to supply us with 492 cells—that is, 8 batteries of 50 cells each, and 12 spare ones (for 110-volt lamps), and the contract price is £3,320, or £6. 15s. per cell, or £27 for four of these cells, which are equal to one cell of the size referred to by Mr. Crompton, against £40 quoted by him. Here I acknowledge that Mr. Crompton has made an error, for he has put the cell at £40, and supplies me with four quarter-size cells equal to it at £27. The normal discharge of this quarter-cell is 105 amperes, the capacity is to be 525 ampere-hours; at the end of such discharge the cells are not to be so exhausted as to cause undue waste when recharging takes place. The next clause (I am quoting an abstract of the contract) provides that the cells are to be capable of discharging at the rate of 200 amperes, and under those conditions they are to have a capacity of 375 ampere-hours. The efficiency at 105 amperes discharge is to be not less than 75 per cent.; the efficiency at 75 amperes discharge is to be not less than 85 per cent.; at 45 amperes discharge it is to be not less than 90 per cent. I must remind you that in practice, although we have a large discharge for a short time, the bulk of our work is low discharge for the longest hours. The cells are to be delivered fully formed. If when the cells are put up the capacity of the cells is not up to the mark, Messrs. Crompton have at their own expense to supply as many extra cells as may be necessary to bring up the total capacity of the battery to that specified for the 480 working cells, so that if the capacity is one-half they must supply as many cells again.

Prof. FORBES: Is there anything in the contract about depreciation?

Mr. J. E. H. GORDON: I am coming to that. If the efficiency is not up to the specification, Messrs. Crompton must at their own expense supply as many extra cells as may be necessary to reduce the discharge per cell to such an amount as shall bring the efficiency up to the contract figure. As to depreciation, Mr. Crompton has here said that he hopes to do it for 15 per cent. His contract with me is for five years; we are bound only year by year—that is to say, as long as we choose we can compel him to keep the cells equal to new for this rate; but if ever we find that we are paying too much, and prefer to do it ourselves, we can stop the contract. He contracts to keep the cells in all respects equal to new for a payment of 12½ per cent. on the contract price, not 15 per cent. or 40 per cent either.

Mr. R. P. SELLON said he was sure they had all been extremely pleased to get from Prof. Forbes some figures on the alternating current in the United States; but the Professor took exception to some facts in Mr. Crompton's Paper, and he criticised his figures so unfavourably that alternating currents were made to appear relatively far more economical than the batteries themselves. First of all he said that in the United States mains were allowed overhead. The Professor therefore thought Mr. Crompton's was an extraordinary large figure for the alternating-current mains, and that they should be cut down to something very much less. He was himself in the United States not many months ago, and he was perfectly certain that through the length and breadth of the United States the alternating-current distribution was carried out by means of overhead mains; but the Yankees would accommodate themselves to circumstances in a way that would not be tolerated in this country. No sane electrical engineer would attempt to lay an installation of 100,000 lights with overhead wires. The moment that they took into account that their mains were going to be laid underground that brought them to this point: that they were in absolute ignorance of what the working of high-tension alternating mains would be when ramified right and left underground. The company to which he (the speaker) belonged had had more experience with high-tension currents probably than any other company in this country, and if they were to judge from the experience that they had had with continuous currents, with 2,000 volts underground and only relatively to a few miles, when alternating-current distribution came to be carried out with a transformer in every house and 2,000 volts laid on, as they said in "John Gilpin," "May I be there to see" (laughter). But what were the objections raised to batteries? As far as he was aware it was this. The secondary battery up to the present had received a very great deal of odium, for this reason: In the case of dynamo machines, or anything else, when an instrument got wrong it let them know—"greased lightning" was seen in a general way (laughter). With batteries they might have a totally different state of affairs. These batteries bore their sufferings meekly, and what was worth so many thousands the night before the following morning had resolved itself into the value of lead. To that fact it was that batteries had up to the present fallen to a great extent into disgrace. The workman had relied upon the fact that these batteries would not complain—he had seen nothing going wrong, and the battery did not change colour, and he supposed that it would be all right (laughter). When they came to distribute in practice on the lines which Mr. Crompton had advocated, and which he (the speaker) imagined every sane man would advocate, namely, distributing from local centres, that difficulty would be entirely removed. The batteries would be placed under the care of somebody who was competent to attend to them; and under these circumstances the main objection, as he understood the matter, to secondary batteries would disappear. There was one point that he should like to ask Mr. Crompton with reference to his Paper. His figures were based upon 400 volts as the E.M.F. of supply—that was for the distribution of 10,000 lights-that was four centres with 2,500 lights each. As Prof. Forbes had stated, the question was not one of 10,000 lights, but 100,000 lights, and when they came to that state of affairs, what was Mr. Crompton going to do? Was he going to increase the number of local centres from a single source of supply and place them in series, or was he going to have a secondary set of main generating stations for every four sub-centres? If he was going to put a larger number than four local centres in series on a single source of generation, the total difference potentially would rise. Under these circumstances the danger arising from leakage, and the inconvenience arising to the householder, would be so great that he must have two sets of batteries, and he must have them split up into two halves, and charge one half while the other was discharging. That involved that the charging should not be on at the same time as the discharging, and the two batteries would have to carry out the whole discharge between them, and therefore the bulk of the battery must be sufficient to meet the demand. If he took the alternative, and did not place more than four local centres on the main generating plant, there again Mr. Crompton met with what certainly modified his figures; and under either alternative, when considering the question of the distribution on a large scale, he must be prepared to modify his figures. To his mind the idea of distribution for the future was really one in which continuous-current transformers and batteries formed the source of supply (applause). Under such circumstances as those the procedure would be this: during a few hours of maximum demand their continuous-current transformers and batteries would go on supplying the current; while about one-half of the time their whole plant would be in operation, but there would be a surplus current supplied which would go to charge the batteries. During the period of medium demand, which would be one-third, say, of the whole 24 hours, their accumulators alone would supply the necessary current. Such a system as that met the objections to both systems which were the subject of Mr. Crompton's Paper. They obtained the advantage of storage, the advantage of motive power; yet, on the other hand, they did not require a sufficient bulk of battery to supply the whole of their current. If they once had their local centres—and they must have local centres, whatever system of distribution they had—it really did not matter in the least whether their apparatus was an apparatus revolving or whether it was an apparatus that was stationary.

The first question which we have to consider in comparing the systems is supposing that both are working over the same area, which is to be preferred by the public? My own impression is that the battery system would carry the day, even though one shilling per unit were charged instead of 7½d. In the first place they are afraid of the high tension system, and also are prejudiced in favour of the idea of pumping into a reservoir, from which you draw as required, and it appears to them, from a common sense point of view, that this is more reliable than depending on moving machinery. Battery systems must be divided into two distinct classes: those in which the battery is charged in the daytime and afterwards separated from the dynamo and discharged on to the lamps—in this case the depreciation will amount to 15 per cent. and the efficiency to 70; the second system is where dynamo and cells are run together during the heaviest part of the lighting, when the depreciation will be about 7 per cent and the efficiency 85 or 90 per cent. There seems to be a prevailing notion that the very presence of batteries in the installation involves the loss of 40 per cent of all the current used in the lamp. This is not the case; it is only the current which goes into the batteries and is reconverted back again that suffers any loss. If a charging current of 500 volts is employed there will be no danger to life, no loss in conversion of the current used by the lamps to the full extent of the dynamo output, there can be no sudden breakdown, the station can be worked with one shift of men, and the engine constantly kept going at the point of greatest economy. Under these circumstances, I cannot but think that batteries will compare very favourably with secondary generators. The main question is the depreciation of the batteries, and I quite agree with Mr. Sellon that the past is no criterion, for they have been placed in isolated installations in the hands of people who have no idea how to use them. Batteries properly looked after will last twice or three times as long as those which are not under supervision. There is another case to which I would refer, probably the oldest batteries in London, namely, those at the P. and O. offices, the plates for which were made even before we became connected with the Storage Company. These cells have lasted four years, and are now in perfect order; a result entirely due to the way in which Mr. Hall, the engineer, has looked after them. That batteries can be seen which have been worked in this way clearly shows that they can be relied upon under certain conditions; but for the present I do not agree with Mr. Crompton that in first cost and maintenance they can be made to compare with the secondary generator system. Where expense is the main object the district is spread, and large halls have to be lit more than private houses, the alternating system will undoubtedly be most used. But I do not attach much importance to the fact that in America the transformer system is the only one

Digitized by Google

which has made any way, for the Americans have practically only one company who are devoting themselves to making secondary batteries, and they came over to England only a year or so back to learn how to make them. If the same amount of brain and time had been expended on batteries in America as on transformers we should no doubt have heard from Professor Forbes of the hundreds of tons of batteries he saw, as well as the large quantities of transformers. Automatic contrivances will, no doubt, be useful, but I see no reason why the system should not be started without them, provided the cells are put in central distributing depots, for the man in charge can easily switch the batteries in and out as required by hand. Finally, I am of opinion that both systems can be made to work quite satisfactorily and to pay their way, but I am convinced that the question as to which system is most largely adopted for the next few years in England will depend very much more upon the engineers than upon the system itself; whichever gets the best men in the early days will become fashionable, and more time will be devoted to its development. If the battery system only receives the same attention as the secondary generator system, and good practical engineers are interested in its development, I cannot but think that the battery system will hold its own both now and in the future.

Mr. FRANK KING said as the first man in England who had put into practice what Mr. Crompton had written about, he had listened to the Paper with great interest. He thought that Mr. Crompton might have gone a little further in discharging arrangements, so as to utilise a higher tension for that purpose. He used an E.M.F of 1,250 volts at Colchester; that was running $2\frac{1}{2}$ years, and they had had not the slightest difficulty with the cables or dynamo machines, although the material that the cells made of was giving way. There was every incentive for the insulation cables and the dynamos to break down, but they did not. When the cables were taken out they were nearly as perfect as when they were laid down. He should, perhaps, in almost every instance with a secondary battery prefer to use a potential up to 2,750 volts. He was quite sure the insulation of the battery could be made so perfect as to allow of that being safely used, and not only so far as the consumer was concerned, but safely as far as the attendants were concerned. In another installation that he laid down some four years ago, at Mr. Alfred Rothschild's mansion, they were charging a set of batteries with an E.M.F. of 535 volts through something like a mile of charging cable, and in that instance the cable, which was of a light nature, as that at Colchester, had never given the slightest trouble from insulation. He merely mentioned this to draw attention to the fact that Mr. Crompton might have gone considerably further with the potential for charging, and, consequently, saved a very large amount for charging the cables. The next point was that Mr. Crompton only used four distributing stations, and he (the speaker) was very confident that he would find that the E.M.F. would vary very considerably. He himself should use for the same purpose at least ten battery stations, or, if the area was a good one, something like Kensington, he might go as low as six. In what was known as the B. T. K. system they charged their batteries in two halves during the day, and as a matter of fact nine hours actually worked was sufficient for the whole three and a-half or four hours for which the consumption was required. With regard to the durability of storage batteries, they had inherent defects in themselves which had until lately been overlooked. But there was not the slightest reason why a battery should not be made in which it was absolutely impossible for any internal action to take place which would run that battery down, and he thought that it would be agreed that unless such action did take place there was no reason to doubt that the storage battery would remain in order. In fact, he had advised his own Company, wherever batteries were used in such manner as he himself had advocated, that they would be able to make 50 per cent. profit if they guaranteed to keep them in order at 12 per cent. There was one thing that he should like to say to all engineers proposing to use storage batteries, if they attempted to charge a number of storage batteries in parallel they would most certainly come to grief. Storage batteries must be charged in a series, so that every cell obtained an identical charge with its neighbours, and they must also be discharged in series, and the result would be that the battery would keep in order.

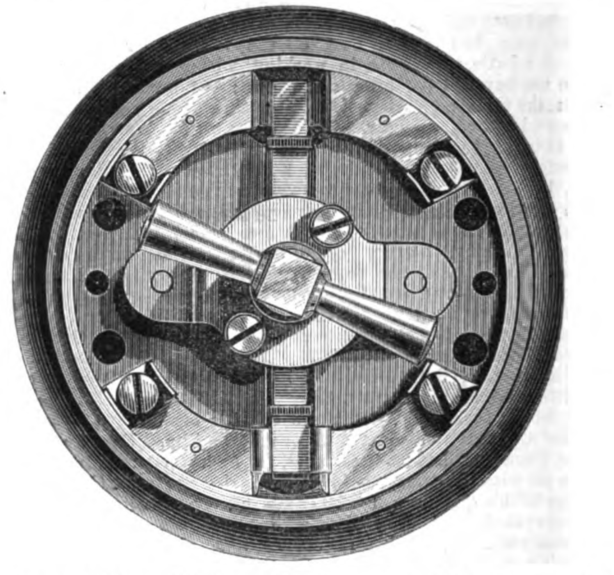
Mr. STEWART RUSSELL said that Mr. Crompton had really based a great deal of his argument in favour of the battery system on the great difficulties with which they would be met when they tried to use conductors for high-tension currents. He had looked up a few instances in which underground cables had been successfully used, and just as several of the speakers had pointed out with regard to batteries, they must not judge of what was going to be done by the earlier failures. Mr. Sellon had referred to the very disastrous experience which their Company had had in the matter of underground cables, but he would like to ask him how far back that was and of what class of cable, how it was laid and a few particulars about it, instead of being contented with a very general statement from that gentleman; and because, as far as he had been able to see in looking up this question, the failures which had occurred with underground wires had occurred really from a very poor class of cable compared with what they were putting down now. In early efforts cables were insulated with gutta percha, and practically with no mechanical protection at all; or they were insulated with pure rubber, or some resinous material, and drawn into tubes, with the result that the insulation was in many cases damaged. The result was only to be expected, and he believed the same result would have occurred in using such a moderate potential as 100 volts.

After a few words from Mr. FLEETWOOD

The CHAIRMAN announced that the discussion must close and that they would hear Mr. Crompton's reply on the 17th May.

Westinghouse Fittings exhibited by Professor Forbes.

Fig. 1 shows the working parts of a 10-ampere double-pole switch, constructed by the Westinghouse Company of America. It consists of a brass bar pivoted at the centre, the two ends being insulated from one another by two thin slabs of insulation. At either end of the bar are a pair of copper spring contacts about $\frac{1}{4}$in. apart, making contact respec-



tively above and below with the rocking bar. From this arrangement it follows that when the bar is tilted in one direction it passes between the copper springs at each end, and thus completes the circuit across each pair of contacts. When tilted in the reverse direction contact is broken at either end. The tilting of the bar is effected by turning the handle, bringing the spring into play, which presses a projecting stud, first on one side and then on the other side of the centre of the bar, as the handle moves over a double cam. The switch is mounted upon a base of vulcanised rubber.

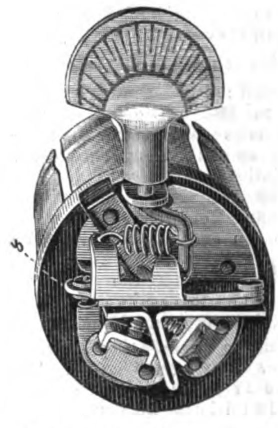


Fig. 2 shows a single lamp switch with the cover off. It has a rubbing double contact at *a*, with spring throw-off. The handle is of metal and is insulated from the contact pin by a washer of ebonite.

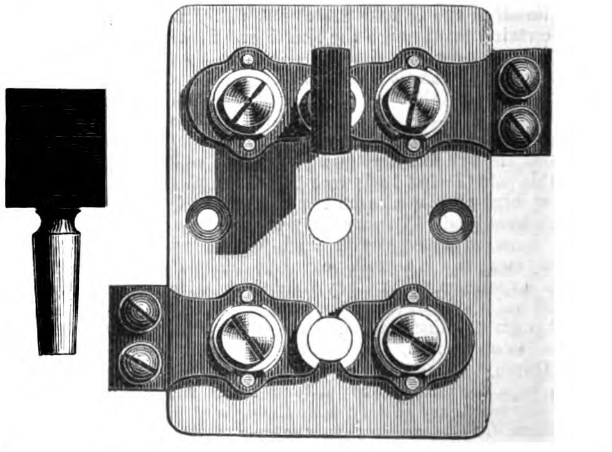

Fig. 3 represents a double-plug switch and fuse block, made of rough copper casting, mounted on a substantial slab of glazed earthenware. The wires are carried into the short tubes or loops at the side.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER IX.—*Magnetic Fields.*

(Continued from page 690.)

105. *Permanent Magnet Controlling Field.*—A galvanometer is usually provided with a permanent magnet, by means of which its sensitiveness may be reduced to any desired extent. This is placed vertically above the needle, and can be shifted vertically so as to vary its effect upon the latter. If it is lowered closer to the needle its force on the latter is increased, and a stronger current through the coil of the instrument will be

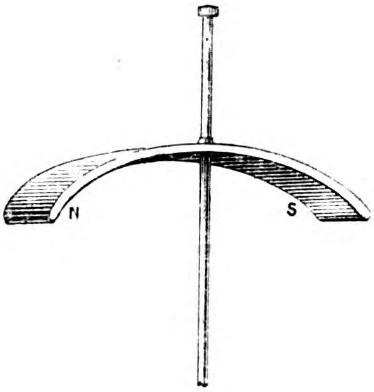

FIG. 65.

required to deflect the needle through a given angle—in other words, the sensitiveness of the galvanometer has been reduced. When the current is stopped, the needle is controlled or directed back to the plane of the coil by the directing action of the field of the permanent magnet. Hence, the magnet is known as a *controlling* or *directing magnet*, and the magnetic-field produced by it in the region of the needle's movement a *controlling* or *directing field*. This controlling magnet is generally placed in such a position that its magnetic-field is in the same direction as that of the earth's horizontal magnetic-field. This is not absolutely necessary in

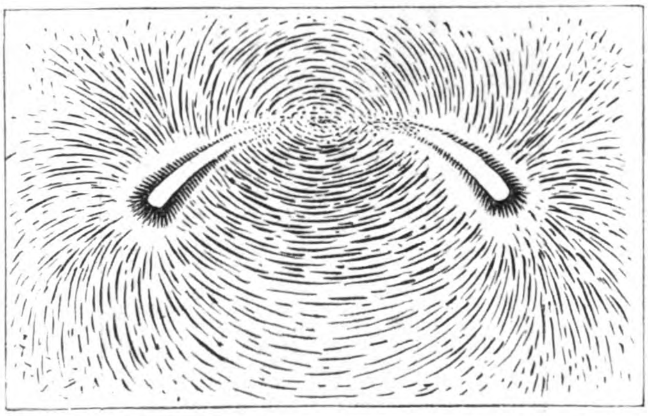

FIG. 66.

ordinary tangent galvanometers, as the tangent law holds good whether the controlling field is that of the earth or a controlling magnet, or both combined; that is, the instrument follows the tangent law equally as well when the controlling magnet keeps the needle parallel to the plane of the coil when no current is on, even though the plane of the coil is not in the magnetic meridian. When this is the case the actual controlling force on the needle is the resultant of that due to the earth and that due to the permanent magnet. In instruments, however, reading absolutely in terms of the controlling field, such as Sir William Thomson's graded potential and current galvanometers, it is absolutely necessary, if a controlling magnet is used, to place it so that its field is in the same direction as that of the earth. This is easily done by first levelling and moving the instrument till the needle is in the same plane as the coil (shown by the pointer being at zero) and then placing the magnet over the needle and varying its position till the pointer stands at zero again; the two fields must then be parallel. In Fig. 65 is shown the controlling magnet of a Thomson reflecting galvanometer. A split brass tube attached to the magnet causes it to grip the vertical guide rod, and remain in any position in which it is placed. The magnetic field surrounding this magnet may be understood by the iron-filing diagram in Fig. 66, which was taken with this magnet. The lines of force are in perfectly regular curves, and it can be seen that by giving the magnet its slightly curved shape the strongest part of the field is thrown downwards towards the needle. Now, in order that

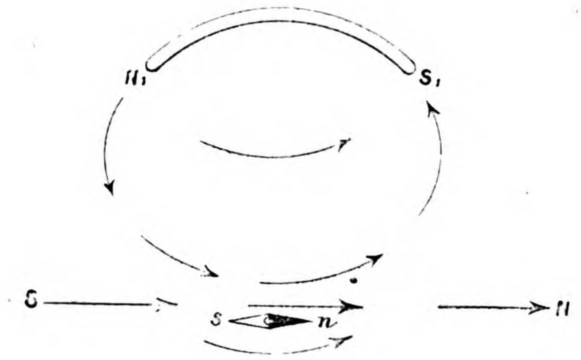

FIG. 67.

this magnetic field shall be in the same direction as that of the earth, the south pole of the magnet must point towards the north pole of the earth. For if the earth's field is represented by the straight arrows N S in Fig. 67, and the curved arrows represent the direction of field due to the magnet $N_1 S_1$, it is

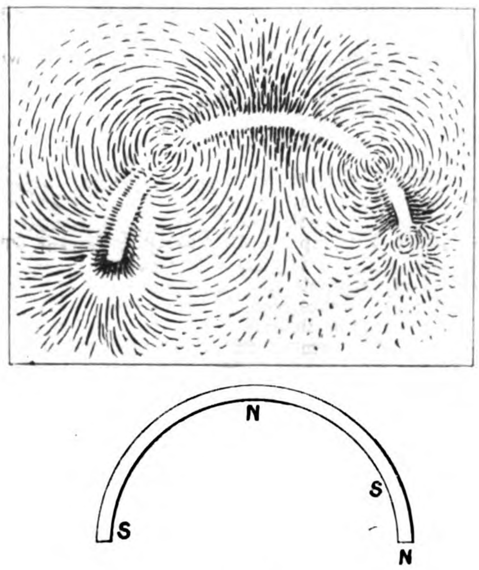

FIG. 68.

evident the two fields will agree in direction when the magnet is so placed—in other words, the lines of force of the two fields must be in the same direction for them to act together; and the *north* pole of a magnetic needle, *n s*, free to turn on its centre, always points *towards* the direction in which the lines of force are assumed to act (para. 104). This last fact is well to bear in mind.

An important point is that the controlling magnet should be magnetised regularly—that is, as in Figs. 65 and 66, where

Digitized by Google

only two poles appear. If more than two poles exist in the magnet we get an irregular field, as shown in Fig. 68, which is taken from an actual magnet with two distinct additional poles. Such additional poles are known as "*consequent poles.*" The diagram of the field of this magnet, taken with iron filings, shows very well the three complete magnetic circuits of lines of force which exist in it. Such a state of affairs had probably been due to this magnet being placed near other magnets, or touching them at different points. To magnetise a controlling magnet regularly the best way is to wrap it round with a layer or two of insulated wire, and then pass a strong current through the wire, tapping the magnet with a mallet to reduce the friction between the molecules of the iron, and allow them to take a permanent set in the direction of magnetisation. A perfectly symmetrical magnetic field is exhibited in Fig. 69, where two semi-circular controlling magnets of an ordinary mirror signalling instrument are placed almost together, with opposite poles *vis-à-vis.* Each magnet completes its own magnetic circuit through the other—that is, instead of all the lines of force branching out from one pole and bending towards the opposite pole of the same magnet, as in the single magnet in Fig. 66, the greater part now branch towards the opposite pole of the other magnet and complete their circuit

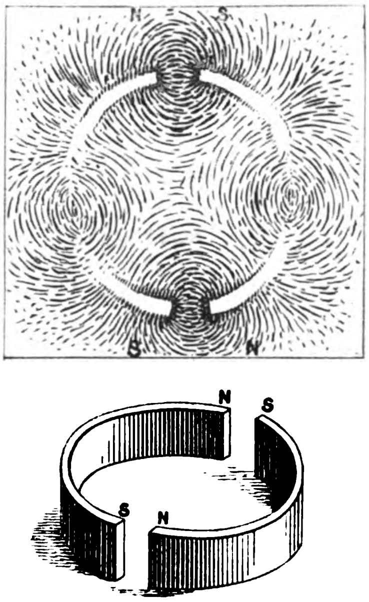

FIG. 69.

through its mass, this being an easier path for them than through the air.

(*To be continued.*)

THE MAXIMUM EFFICIENCY OF INCANDESCENT LAMPS.*

BY JOHN W. HOWELL.

The word efficiency, when applied to an incandescent lamp, is used to designate the amount of energy required by the lamp for the production of a given amount of light. Thus we say that a given lamp has an efficiency of 3 watts per candle, at 16 candles; meaning, that to produce an illumination of 16 candles we must supply the lamp with 48 watts.

The word efficiency, when applied to a prime mover or to any piece of apparatus that changes energy from one form to another, or which transmits or utilises energy, has a well-defined meaning, and is used to represent the ratio of the energy of the useful effect produced by the apparatus, to the energy necessarily supplied to the apparatus to enable it to produce that effect.

An incandescent lamp transforms electrical energy into heat and light, so the use of the word efficiency to denote the watts per candle required by the lamp is not a proper one. To denote properly the efficiency of an incandescent lamp we must be able to separate the energy of the light produced by it from the energy of the heat produced. Then the ratio of the energy of the light to the electrical energy required by the lamp will be a correct expression for the efficiency of the lamp, and we will have to find some other word to designate the watts per candle. In this Paper the word efficiency is used in its ordinary improper sense to denote the watts per candle required by a lamp when producing a given amount of light.

The efficiency of a lamp varies with its candle-power. The curve (Fig. 1) shows the rate of this variation for a particular lamp. At 5 candles this lamp has an efficiency of 6·7 watts per candle; at 10 candles it is 4·2 watts per candle, and at 20 candles it is 2·66 watts per candle.

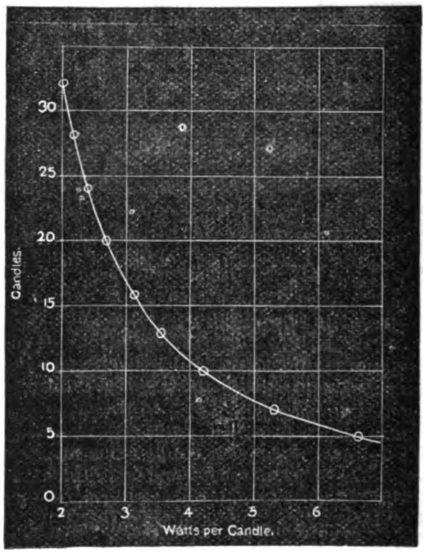

FIG. 1.

Any statement regarding the efficiency of a lamp must therefore be accompanied by a statement of the candle-power at which it has the stated efficiency; without this it is meaningless. There is nothing in an incandescent lamp itself that fixes its proper efficiency or in any way indicates what it is. The lamp from which the curve (Fig. 1) was determined has, within the limits of the curve, any efficiency between 2 and 7 watts per candle. Thus, by simply changing the candle-power of the lamp we can operate it at any efficiency we choose, and get as much or as little light per watt as we choose.

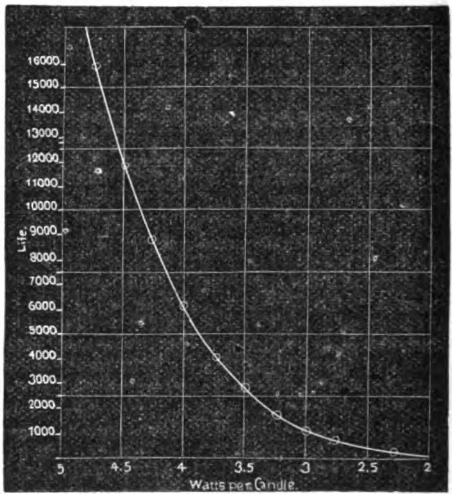

FIG. 2.

In commercial practice the candle-power of lamps is always marked on them, and their efficiency at this candle-power is stated; but even this is not a proper index to the value of the lamp or to its proper efficiency. Experience has shown that lamps are almost universally run above their normal rating; lamps rated at 4·5 watts per candle are usually run at from 3·5 to 4 watts per candle, and in order to make lamps that will stand the strain of being run above their rated capacity, it is necessary to rate them considerably below the efficiency at which they will give the best results under ordinary circumstances.

* A Paper read before the American Institute of Electrical Engineers April 10, 1888.

Digitized by Google

Lamps have been made and sold in England which have a very high rated efficiency; but parties buying these lamps are told that they will get very much more satisfactory results if they run the lamp *below their rated capacity*. So we see that some lamps are rated above their capacity and some are rated below, and the rated efficiency of a lamp is not always the best efficiency at which to run it. How, then, are we to determine the efficiency at which a lamp will give the best results? It is this question which I will attempt to answer.

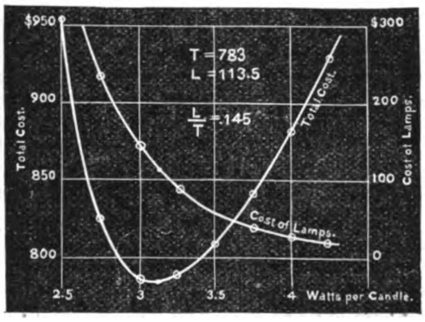
The term "maximum efficiency" of a lamp, as used in the title of this Paper, does not mean the highest efficiency at which a lamp can be operated, but the efficiency at which the best results are produced by the lamp, or, more accurately, *the efficiency at which the cost of operating the lamp is a minimum.*

Taken in this latter sense, the maximum efficiency of a lamp is not its highest efficiency. As we increase the candle-power of a lamp its efficiency increases; consequently, by running the lamp high enough we can make its efficiency so high that very little power is required to produce a given amount of light, and the cost of the power to produce the light is very small. But, while the efficiency of the lamp increases, its life decreases, and if we run a lamp at too high an efficiency the saving in the cost of power is more than balanced by the increased cost of lamp renewals.

To determine the maximum efficiency for lamps under given conditions, we must determine the efficiency at which the sum of the costs of power and lamps is a minimum, and in order to do this we must know the rate of variation of the life of a lamp with its efficiency.

The curve, Fig. 2, shows this rate of variation. This curve is the result of very carefully conducted experiments made by the Edison Company. These experiments extended over five years and consumed a very large number of lamps. Its accuracy when applied to Edison lamps is beyond question; but our experiments with lamps having an artificial surface on the carbon, or "flashed" lamps as they are called, show that their rate of variation of life and efficiency follows a different curve.

Lamps 85c. each—Life 600 hours at 3 Watts per Candle.
Current costs 10c. per H.-P. per hour.



Minimum at 3·1 Watts per Candle. ∴ Maximum Efficiency 3·1 Watts per Candle.

Fig. 3.

This curve does not apply to individual lamps. If we take two Edison lamps and burn them at different efficiencies, their lives for these efficiencies will probably not be such as indicated by the curve, nor will they be proportioned to these indicated lives. But if we take one hundred lamps and burn them at one efficiency, and another hundred equally good lamps and burn them at another efficiency, the average lives of the two sets will be proportional to the lives indicated by the curve for these two efficiencies.

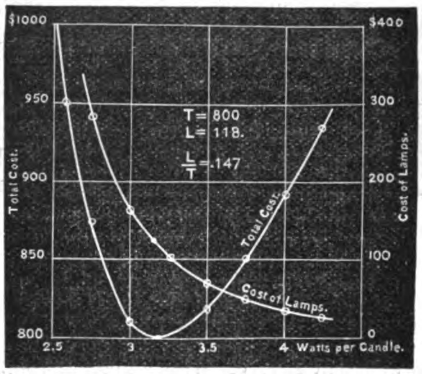
In order to determine at what efficiency the cost of operating lamps of a given quality under given conditions is a minimum we must calculate what this cost is at different efficiencies. To do this we consider the total cost of operating the lamps to be made up of two parts, viz., the cost of the *current* and the cost of the *lamps.* The cost of the current is made up of every expense incurred in operating the lamps, including materials consumed, labour, taxes, insurance, rent, and every other expense incurred in operating the plant, except the cost of lamps. The cost of the lamps is an item by itself, and is the amount which the lamp has cost when it is put in use. This is a natural division of the total cost of operating a plant, since to produce light by incandescence all that is necessary is a lamp and current to operate it.

If, in any case, we know the cost of the current required to operate the lamps, the cost of the lamps, the quality of the lamps—that is, the life they will give when burned at a given efficiency—and the rate of variation of their life with efficiency, we can then calculate at what efficiency the cost of operating the lamps is a minimun, and this I call the maximum efficiency of those lamps.

The following examples show what this maximum efficiency is under varying conditions of the cost of lamps, the cost of current, and the quality of the lamps. The cost of the lamps I have varied between 25 cents and 1.00dol. each. The cost of current varies between 2.5 cents and 10 cents per horse-power per hour. The quality of the lamps varies between 300 hours life at 3 watts per candle and 2,400 hours life at 3 watts per candle.

In each of the following cases I have calculated the cost of operating 100 16 candle-power lamps 1,000 hours, at each of the efficiencies comprised in the curve of total cost. These curves do not show the cost of running the same lamps at different efficiencies, but the cost of running equally good 16-candle lamps of the different efficiencies.

Lamps $1.00 each—Life 600 hours at 3 Watts per Candle
Current costs 10c. per H.-P. per hour.



Minimum at 3·18 Watts per Candle.
∴ Maximum Efficiency 3·18 Watts per Candle.

Fig. 4.

The first case we will consider is shown in the diagram Fig. 3. In this case the lamps are assumed to cost 85 cents each, and to have a life of 600 hours at 3 watts per candle. The current is assumed to cost 10 cents per horse-power hour.

The cost of the current is determined from the following formula:—

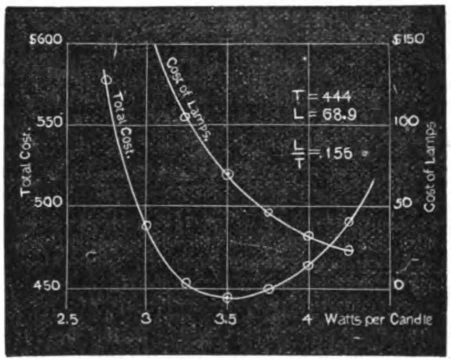
Current cost

$$= \frac{\text{w. p. c.} \times 16 \times 100 \times 1{,}000 \times \text{cost of ct. per h.-p. per hour}}{746}.$$

And the cost of lamps from this formula:—

$$\text{Cost of lamps} = \frac{\text{cost of one lamp} \times 100 \times 1{,}000}{\text{life at given efficiency}}.$$

Lamps $1.00 each—Life 600 hours at 3 Watts per Candle.
Current costs 5c. per H.-P. per hour.



Minimum at 3·5 Watts per Candle.
∴ Maximum Efficiency 3·5 Watts per Candle.

Fig. 5.

The curve marked *total cost* shows the total cost of running 100 16 candle-power lamps 1,000 hours, the efficiencies of the lamps varying between 2·5 and 4·25 watts per candle. The efficiencies are shown by the vertical lines, referring to the scale at bottom. The value of the total cost at any point of the curve is shown by the horizontal line through the point, referring to the scale at the left of the diagram.

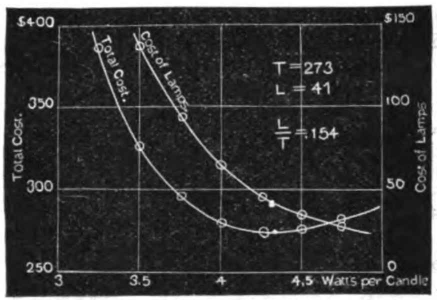
The lowest point of the curve shows the point where the total cost is lowest. This is the minimum cost of operating these lamps under the given conditions. The mark at the lowest point of the curve shows this minimum cost to be 783dols., and a vertical line through this point to the scale at bottom of the diagram shows

that this total cost is a minimum when lamps having an efficiency of 3·1 watts per candle are used.

Thus the maximum efficiency of these lamps under the conditions assumed is 3·1 watts per candle.

The lamps considered in the case shown in Fig. 4 cost 1.00dol.; all other conditions are the same as in the case shown in Fig. 3. This increases the total cost from 783dols. to 800dols., and necessitates using lamps of 3·18 watts per candle instead of 3·1, to make the cost of operating a minimum.

Lamps $1.00 each—Life 300 hours at 3 Watts per Candle.
Current costs 2.5c. per H.-P. per hour.

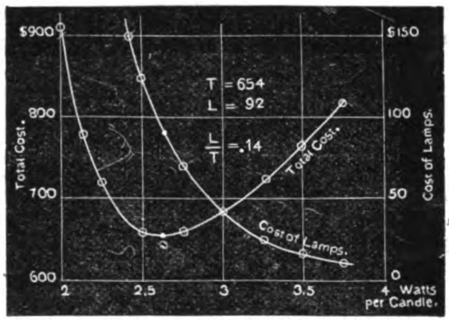


Minimum at 4·32 Watts per Candle.
∴ Maximum Efficiency 4·32 Watts per Candle.

FIG. 6.

In the case shown in the diagram, Fig. 5, the current costs 5 cents per horse-power hour; the other conditions are the same as in the case assumed in Fig. 4. The minimum total cost in this case is 444dols., and to make this cost a minimum we must use lamps having an efficiency of 3·5 watts per candle.

Lamps 50c. each—Life 1,200 hours at 3 Watts per Candle.
Current costs 10c. per H.-P. per hour.

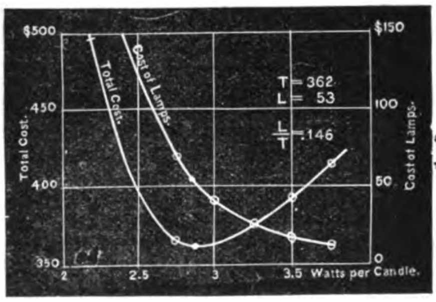


Minimum at 2·62 Watts per Candle.
∴ Maximum Efficiency 2·32 Watts per Candle.

FIG. 7.

In the case shown in Fig. 6 the lamps cost the same as in the last, but are only half as good; the current costs just half as much as in the last case. The minimum total cost in this case is 273dols., and the maximum efficiency of the lamps is 4·32 watts per candle.

Lamps 50c. each—Life 1,200 hours at 3 Watts per Candle.
Current costs 5c. per H.-P. per hour.

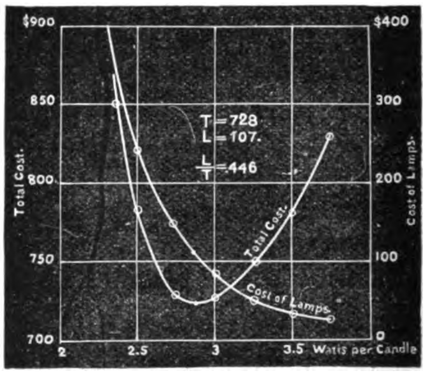


Minimum at 2,875 Watts per Candle.
∴ Maximum Efficiency 2·88 Watts per Candle.

FIG. 8.

In the case shown in Fig. 7 the lamps cost 50 cents, and have a life of 1,200 hours at 3 watts per candle. The current costs 10 cents per horse-power per hour. This is the cheapest and also the best lamp we have yet considered, but the current is expensive. In this case the minimum total cost is 654dols., and the maximum efficiency of the lamps is 2·62 watts per candle. In this case, Fig. 8, the current costs half as much as in the previous case, other conditions being the same. The minimum total cost is reduced from 654dols. to 362dols. The maximum efficiency in this case is 2·88

Lamps 50c. each—Life 600 hours at 3 Watts per Candle.
Current costs 10c. per H.-P. per hour.



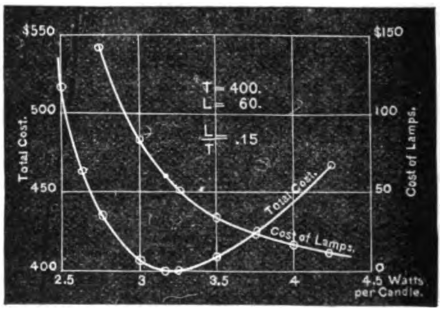
Minimum at 2·88 Watts per Candle.
∴ Maximum Efficiency 2·88 Watts per Candle.

FIG. 9.

watts per candle. In Fig. 9 the current costs twice as much as in the previous case, and the lamps are only half as good. The minimum total cost is doubled, but the maximum efficiency is the same as in the previous case.

In this case (Fig. 10) the current costs one-half of that assumed in the previous case, other conditions being the same. The minimum total cost is 400dols., and the maximum efficiency 3,175 watts per candle.

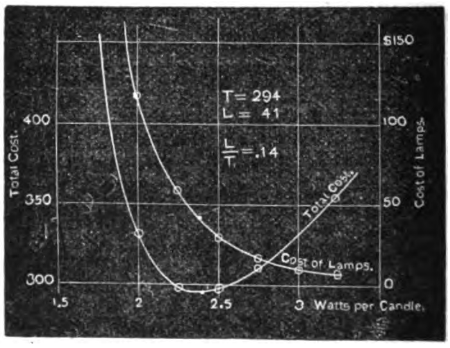
Lamps 50c. each—Life 600 hours at 3 Watts per Candle.
Current costs 5c. per H.-P. per hour.



Minimum at 3·175 Watts per Candle.
∴ Maximum Efficiency 3 175 Watts per Candle.

FIG. 10.

Lamps 25c. each—Life 2,400 hours at 3 Watts per Candle.
Current costs 5c. per H.-P per hour.



Minimum at 2·38 Watts per Candle.
∴ Maximum Efficiency 2·38 Watts per Candle.

FIG. 11.

The curve (Fig. 11) illustrates the case of very cheap and very good lamps, with moderate cost of current. The minimum total cost is low, 294dols., while the lamps are run at the high efficiency of 2·38 watts per candle.

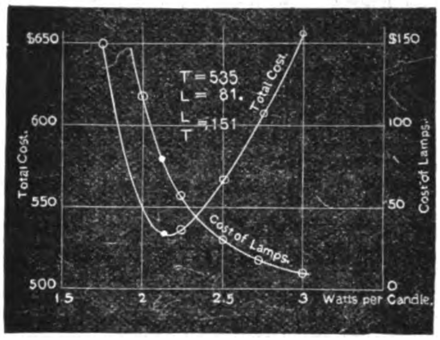
Digitized by Google

In the case shown in Fig. 12, the cost and quality of the lamps are the same as in the previous case, but the current costs twice as much. This increases the minimum total cost from 294dols. to 535dols., and raises the maximum efficiency to 2·14 watts per candle.

In the case (Fig. 13) the cost of lamps and the cost of current are the same as in the case shown in Fig. 11, but the lamps are only half as good. The minimum total cost is increased from 294dols. to 327dols., and the maximum efficiency is reduced from 2·38dols. to 2·62 watts per candle.

The first and plainest inference drawn from these curves is that the maximum efficiency of any given lamp is not a fixed one, but varies with conditions outside the lamp itself. Identical lamps operated under different conditions of cost of current must be

Lamps 25c. each—Life 2,400 hours at 3 Watts per Candle.
Current costs 10c. per H.-P. per hour.



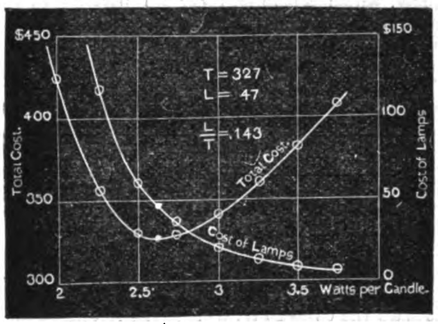
Minimum at 2·14 Watts per Candle.
∴ Maximum Efficiency 2·14 Watts per Candle.

FIG. 12.

burned at different efficiencies to make the cost of operation a minimum for the production of a given amount of light. In order to determine the maximum efficiency of lamps, therefore, we must know the quality of the lamps referred to some standard, the cost of the lamps to the consumer, and the cost of current under the actual conditions existing at the place where the lamps are to be used.

In the eleven cases shown in this Paper the lamp of highest efficiency is obtained in the case shown in Fig. 12. This is a case where the lamps are very cheap and very good, and current is very expensive. The lamp having the lowest efficiency is obtained in the case shown in Fig. 6, in which the lamps are poor and high-priced and the current is very cheap.

Lamps 25c. each—Life 1,200 hours at 3 Watts per Candle.
Current costs 5c. per H.-P. per hour.



Minimum at 2·62 Watts per Candle.
∴ Maximum Efficiency 2·62 Watts per Candle.

FIG. 13.

There is a marked difference in the sharpness of these curves at the minimum points. An inspection will show that the sharpness of the bend in these curves depends upon the cost of the current, the curves in which the current costs 10 cents per horse-power per hour being the sharpest. Those in which the current costs 5 cents are next, and the one (Fig. 6) in which the current costs only 2½ cents per horse-power per hour is very flat at the bottom or minimum point. In this comparison Fig. 7 is not considered, as it is drawn on a different scale from the others, and is not as sharp as it should be.

This indicates that the more expensive the power is the more carefully must the lamp efficiencies be chosen. In Fig. 12, which shows the sharpest curve, a very slight variation in the efficiencies of the lamps makes a very great change in the total cost of operation.

In the case shown in Fig. 6, in which the current is very cheap, we find that a very considerable change in the efficiency of the lamps used makes very little difference in the total cost or operation.

On each of the eleven diagrams two curves are drawn, one showing the total cost of the operation and the other showing the cost of lamps. On each of the curves showing the cost of lamps a point is marked which indicates the cost of the lamps when the total cost is a minimum. The letter T marked on each of the figures denotes the minimum total cost of operating the lamps under the given conditions. The letter L denotes the cost of the lamps when the total cost is a minimum, and the expression $\frac{L}{T}$ denotes the ratio of the cost of lamps when the total cost is a minimum, to the minimum total cost. An examination of all these curves shows that while the minimum total cost varies with each of the three quantities—price of lamps, quality of lamps, and cost of current—nevertheless, *the total cost is always a minimum when the cost of lamps is about 14·5 or 15 per cent. of the total cost of operation.*

This figure varies somewhat in the different examples considered, but the variation seems to follow no law. In Figs. 6 and 12, which show the highest and lowest efficiency lamps, the figures are 15·1 per cent. and 15·4 per cent. respectively.

The steepness of the curve showing the cost of lamps, and the difficulty of determining the exact minimum point of a curve which has been drawn by inaccurate methods, makes it difficult to get the cost of lamps accurately when total cost is a minimum. These curves and values are given just as they were determined, and no effort has been made to bring the results into closer agreement, as could readily have been done. I consider the variation shown by these curves to indicate closely enough that this ratio of cost of lamps to total cost at the minimum point is nearly, if not quite, constant, and that its value is between ·145 and ·15.

This establishes a very simple law for determining whether or not lamps are being operated at their maximum efficiency; for if they are, the lamp bills will be about 15 per cent. of the total operating expenses of the plant. If the lamp bills are more than 15 per cent. of the total operating expenses the lamps are being burned above their maximum efficiency, and lower efficiency lamps should be obtained. If, on the other hand, the lamp bills are less than 15 per cent. of the total expenses of the plant the lamps are being burned below their maximum efficiency and higher efficiency lamps would reduce the cost of operating the plant. Where fuel is high-priced, or where other causes operate to make the cost of generating current high, it is specially important to use lamps of the maximum efficiency, for we have seen from the above curves that where the cost of current is high the use of lamps whose efficiency is a little above or below the maximum efficiency attainable under the conditions of operation makes a very marked increase in the operating expenses of the plant.

If in any plant the lamp bills are only 10 per cent. of the total expenses, then *increasing the efficiency of the lamps by increasing their candle-power does not diminish the total cost of operating the plant.* In order to reduce the total cost *the lamps must be replaced by lamps of the same candle-power but of higher efficiency.* If the efficiency of the lamps is increased by raising their candle-power, the cost of operating the plant *per unit of light produced* is reduced, but the total cost is increased. A plant which is paying less than 15 per cent. of its total expenses for lamps, and which brings the lamp bills up to 15 per cent. by increasing the candle-power of the lamps does not decrease the cost per lamp of operating the plant, but *does* decrease the cost per candle of light furnished. If they are paid for the increased light given by the lamps the efficiency of the plant is made a maximum for the existing conditions; but if they are not paid for the additional light furnished the efficiency of the plant is reduced.

This law enables any one operating an incandescent lamp plant to determine whether or not he is using the most suitable lamps for his plant. If the conditions of operation of a new plant are all known, and the quality of the lamps made by any lamp maker is known, we can determine before starting what is the most economical lamp to use.

JUDGMENT OF THE SUPREME COURT OF THE UNITED STATES IN THE TELEPHONE APPEALS.

(Concluded from page 668.)

DRAWBAUGH FAILS TO REPRODUCE HIS ALLEGED RESULTS.

But there is another fact in this case equally striking. As has already been seen, F, D, C, and I were in no condition for use when they were produced and put in evidence. They were mere remains. No one but Drawbaugh himself could state how they were made or how they were to be used. He undertook to reproduce some of them, especially F and G. This was in the latter part of 1881, while the testimony was being taken. The Bell Company proposed that they should be tried, to see if they would do what the witnesses said had been done with the originals, which the remains show must have been exceedingly primitive in their character;

The testimony also shows that when they were originally used, by or in the presence of the witnesses, no particular care was taken in their adjustment. They were lying around in the shop or placed upon shelves. Some say that when the experiments were made they were held in the hands or allowed to stand on a table. In order to reach satisfactory results Drawbaugh himself said in his deposition :—

"I had persons in the cellar reading printed matter, some advertisement or something, and I could hear the words that were read ; and at other times I would go down into the cellar and read something and come up, and they would repeat the words to me that I had read."

The proposition of the Bell Company was accepted, and the reproductions were tried in March, 1882, under the most favourable circumstances. It is substantially conceded that the trial was a failure. Occasionally a sound was heard and sometimes a word, but it would not transmit sentences. At the time of these experiments F, which was the transmitter, was placed on a table as Drawbaugh said it was originally.

Two years afterwards other reproductions were presented, differently constructed and used in a different way. Those would talk, but they were neither the same nor used in the same way as the originals. To our minds, the result of the experiment conclusively shows that the original instrument could not have been of a construction similar to the reproductions, and that what they had done was produced by some other means.

We do not doubt that Drawbaugh may have conceived the idea that speech could be transmitted to a distance by means of electricity, and have experimented upon that subject. But to hold that he discovered the art of doing it before Bell did would be to construe testimony without regard to the ordinary laws that govern human conduct. Without pursuing the subject further we decide that the Drawbaugh defence has not been made out.

THE ALLEGED FRAUD IN THE PATENT OFFICE.

Another objection to Bell's patents put forth in the oral argument of Mr. Hill, and in the printed brief signed by him, and in that signed by Mr. Dixon, is that the application as originally filed in the Patent Office did not contain his present fourth claim, or any description of the variable-resistance method, and that all which now appears in the specification on that subject, including the fourth claim, was surreptitiously interpolated afterwards. Bell's application was filed February 14th, 1876, and afterwards, during the same day, Elisha Gray filed a caveat in which he claimed as his invention "the art of the transmission of vocal or other sounds or conversation telegraphically, through an electric circuit," and in his specification described the variable-resistance method. The precise charge now made in the printed brief of Mr. Hill is :—

"That Mr. Bell's attorneys had an underground railroad in operation between their office and Examiner Wilber's room in the Patent Office, by which they were enabled to have unlawful and guilty knowledge of Gray's papers, as soon as they were filed in the Patent Office ; and that an important invention and a claim therefor were bodily interpolated into Bell's specification between February 14th, 1876, and February 19th, 1876, by Pollok, in consequence of the guilty knowledge which the latter already had of the contents of Gray's caveat before the declaration of interference with Gray on February 19th."

So grave a charge, made in so formal a manner, is entitled to consideration. It involves the professional integrity and moral character of eminent attorneys, and requires us to find from the evidence that after Bell swore to his application on the 20th of January, 1876, and after the application thus sworn to had been formally filed in the Patent Office, an examiner, who got knowledge of the Gray caveat put in afterwards, disclosed its contents to Bell's attorneys, and they were then allowed to withdraw the application, change it so as to include Gray's variable-resistance method, over Bell's signature and over the jurat, and then to restore it to the files thus materially altered, as if it were the original, and all this between February 14th and February 19th. Although much stress was laid in the argument on the fact that what purported to be a certified copy of the specification of Bell, as found in the file-wrapper and contents printed in the Dowd case, differed materially from the patent, the occasion of these differences has been explained in the most satisfactory manner.

We entertain no doubt whatever that the specification, as now found in the patent, is precisely the same as that on which the order to issue was made. If any alterations were made they were all done before February 19th, and the fair copy which is now found on the files of the office is precisely as it was when the order for the patent was granted ; not a shadow of suspicion can rest on any one.

All that remains, therefore, on which to rest this serious charge is that in a paper handed by Bell to George Brown, of Toronto, describing his invention, and which was intended to be used in England to secure a British patent, there is now claimed to be an interpolation which in the American application is not to be found. It is but right to say that during the whole course of the protracted litigation about the Bell patent no argument was ever presented based on this discrepancy until the brief of Mr. Hill was filed in this court on Jan. 18, 1887, six days before the argument on these appeals was begun. So far as we are advised, nothing has ever before occurred in the cases that seemed to make it necessary to prove when the variable-resistance method, or the fourth claim, was put into the American application, or why it was left out of the paper handed to Brown. It seems always to have been assumed, until the cases got here, that because it was in the American patent it was rightfully there. Certainly there is nothing in the pleadings in any of the cases to direct attention to the materiality of this fact. A comparision of the paper handed to Brown with the American application shows that they differ in more than thirty different places, besides those which relate to the variable-resistance method and the fourth claim. The differences are generally in forms of expression, this indicating that one was written after the other, and evidently for the purpose of securing greater accuracy. The paper handed Brown was merely a rough draft and not a fair copy, for the record shows that it bears on its face the evidence of numerous erasures and interlineations. Bell says in his testimony that he began writing this specification in October, 1875, and wrote and rewrote it a number of times, and fially adopted that mode of expression which seemed to him best to explain the invention and the relation which one portion bore to another. He visited Brown in Canada in September, and again in December, 1875. An arrangement was made between them on the 29th of December, at the last interview, by which Brown was to interest himself in getting out the British patent. Other inventions besides the telephone were included in the contract entered into for that purpose. Bell returned to Boston on the 1st of January, and immediately set himself to work to complete his specification. It was taken to Washington by Mr. Hubbard, about the 10th of that month, and delivered to Pollok and Bailey, his attorneys. It was then examined by his attorneys and found correct, and a fair copy made, and then returned on the 18th to Bell, for his signature. It was signed and sworn to in Suffolk County, on January 20th, and immediately returned to the attorneys. Afterwards Mr. Pollok met Bell in New York, and it was again gone over with care by the two together. No change whatever was made in it at that time, and Mr. Pollok took it back with him to Washington.

On the 25th of January, 1876, Bell met Brown, who was then on his way to England, in New York. It is now assumed that the papers which Brown took to England were handed to him then ; and because the variable-resistance method in the fourth claim was not in it, it is argued that it could not have been in the American specification at that time. But no one has said when the paper was actually handed to Brown. Bell says he cannot tell, but it must have been after he made his contract with Brown on the 29th of December. As the American specification was signed and sworn to five days before the interview with Brown on the 25th of January, and the paper of Brown differs from it in so many particulars besides that now in question, it would seem to be clear that the paper was a copy of some former draft that Bell had made and possibly taken to Canada in December, not that which was perfected afterwards. As the specification which had been prepared and sworn to was a fair copy, without erasure or interlineation, the fact that the paper handed to Brown was not a fair copy would imply that it was not intended to be an exact transcript of the other.

At any rate, the bare fact that the differences exist under such circumstances is not sufficient to brand Bell and his attorneys and the officers of the Patent Office with that infamy which the charges made against them involve. We therefore have no hesitation in rejecting the argument. The variable-resistance method is introduced only as showing another mode of creating electrical undulations, and that Bell had his mind upon such a method is conclusively established by a letter which he addressed to Mr. Hubbard on the 4th of May, 1875, and which is in the Dowd record, introduced into the Overland record by stipulation. Its insertion in his final draft of his specification is another proof of the care with which the work had been done.

INCORPORATION OF THE BELL COMPANY.

In the case of the Clay Commercial Company objection was made to the sufficiency of the proof of the incorporation of the American Bell Telephone Company. The first point is as to the act incorporating the American Bell Company, which authorised certain persons therein named to form a corporation; and second the certificate of the Secretary of the Commonwealth, in the form required by Section 111, Chapter 224, that certain persons, among whom were the members of this company, under the name of the American Bell Telephone Company were legally organised. This section made such a certificate conclusive evidence of the existence of a corporation organised under that Act. The authority granted by the special Act to the persons named to organise as a corporation in this way, gave them the authority to select a corporate name, and also made the statutory certificate conclusive evidence. The objections to the proof of title are not, in our opinion, well taken. We do not think it necessary to add to the length of this opinion by referring to the testimony upon that point.

THE SECOND BELL PATENT.

This disposes of all the cases so far as the patent of March 7th, 1876, is concerned. It remains now to consider only the other patent. It received but little attention by counsel or Court in either of the cases below. In the Dolbear case it was by consent excluded from the decree.

In the case of the Clay Commercial Company it was alleged in the answer that substantial and material parts of the things described and claimed were described and claimed in a prior British patent taken out December 9th, 1876, and inasmuch as the foreign patent does not bear the same date, if the American patent is not limited it is void. This point has not been pressed in the argument. In our opinion it has been settled by the decisions of this Court in *O'Reilly* v. *Morse* and in *Siemens* v. *Sellers* at the present term, that the effect is not to render it invalid if it is for the same invention, but only to limit its term. The patent in itself is for the mechanical structure of an electric telephone, to be used with the electrical action on which the first patent rests. The *third* claim is for the use, in such instrument, of a diaphagm made of a plate of iron or steel, or other material capable of inductive action ; the *fifth* is for a permanent magnet ; the *sixth* for a sounding box ; the *seventh* for a speaking or hearing tube, and the *eighth* for a permanent magnet and plate combined. The claim is not for these several things, but for an electrical telephone, in the construction of which those things or any of them are used. Hence the fifth claim is not anticipated, as was decided in the Molecular case below. The patent is not for a magnet, but for a telephone of which it forms a part To that extent the decree in that case was erroneous.

Digitized by Google

THE DECREE.

It follows that the decree in each of the cases so, far as it is in favour of the Bell Company and those claiming under it, must be affirmed, and that the decree in the Molecular case, so far as it is against that company on the fifth claim of the patent, must be reversed, and a decree directed to that extent in its favour. It is accordingly so ordered.

Mr. Justice Gray was not present at the argument, and took no part in the decision of these cases.

JUSTICES BRADLEY, FIELD AND HARLAN DISSENT.

At the conclusion of the reading of the opinion of the Court, Mr. Justice Bradley made the following remarks:—

Mr. Justice BRADLEY: Mr. Justice Field, Mr. Justice Harlan and myself are not able to concur with the other members of the Court in the result which has been reached. The point on which we dissent is the question of Drawbaugh's invention. We think that Drawbaugh did anticipate the invention of Mr. Bell. We think that the evidence to that point is so overwhelming, both with regard to the number and character of the witnesses, that it cannot be overcome. Of course, it is a question of fact depending upon the weight of the evidence, and involves no question of law, and, therefore, it is a matter that does not require much observation on the part of those who dissent from the opinion, which is very ably drawn, and undoubtedly presents the whole case with great force. But on this point we cannot concur in the views of the Court. We think that Drawbaugh did have an instrument in his shop as early as 1869 which used the variable-resistance instrumentality in transmitting articulate speech to a distance, by means of electricity, and was distinctly heard and understood. That is the whole invention, so far as variable resistance is concerned.

We also think that as early as 1871 he did produce an instrument employing the magneto-electric instrumentality altogether, substantially the same as that which is claimed in Mr. Bell's patent. In the one case, with regard to the variable-resistance principle, over seventy witnesses were produced. The evidence of some of them may have been shaken with regard to the time that they had in mind; but the evidence of the great majority of them is not shaken at all. They were mostly plain people of the country, but they heard the words, and that is a matter that they could not be mistaken about. It did not require science nor literature nor refinement to understand that.

In regard to the other instrument, some 40 or 50 witnesses were produced who saw it. Many of them heard the language produced through it, and a number of witnesses who did not hear the language produced through these instruments, saw them or heard them talked about, so as to fix the time that they were in existence, and it seems to us that on this subject of time and of result there is such a cloud of witnesses that it is impossible not to give credence to them. There is no doubt that Mr. Bell's merits are very great in appreciating the importance of the discovery, and in bringing it before the public in such a manner as to make it appear to be what it is, one of the most important discoveries of the century. He was a man whose professional experience and whose scientific attainments enabled him to see at a glance the importance of it. Drawbaugh was a different sort of man. He did not see it. Had he done so, he would have taken measures to interest persons with him in it, and have brought it out. He was a mechanic, a plain mechanic, somewhat better instructed, perhaps, than most ordinary mechanics, a man of more reading, a man of more intelligence. But he looked upon what he made more as a curiosity than a matter of speculation, a matter of financial importance or of importance to the public. That is the way we view his condition of mind in regard to it, and explain why he had not taken more pains to bring it forward to the notice of the public. It is the tendency of the human mind to attach importance to the results and inventions of those who have achieved eminence. Watt was the idol of the British nation, from the time of his first invention of the steam engine until the day of his death, and until the present time; and everything that was invented about the steam engine was attributed to him. It was the glory of England, the glory of Watt, and of course every patriotic British subject would hoot at anything it was claimed Watt did not invent, or attribute it to him. That is a principle of the human mind on which we think a great deal may be explained with regard to the feeling towards this important service which Mr. Bell has rendered with regard to this invention. The plain mechanic of Pennsylvania is of no account. The scientific and illustrious—for he is illustrious—Mr. Bell, it cannot be but that he did invent this thing! And yet if Mr. Bell on the 14th day of January (I think it was) or February, when he applied for his patent at the Patent Office, had had in his laboratory the things that Drawbaugh had, he would have been filled with an excitement far exceeding that which has animated the great inventors of the world when they made the discoveries they have made, and he would have exclaimed, "Eureka! Eureka!" He would have appreciated it if Drawbaugh did not.

What had he when he applied for his patent? On the 10th of June, 1875, they thought they heard something, but were not sure; but he knew the principle, and he patented it. Up to the time of making his application for a patent they had not succeeded in producing intelligible speech, more than a word or two; perhaps a word or two. If Bell had done at that time as much as Drawbaugh had done according to the evidence, he would have had no hesitation in claiming the greatest discovery that the world has seen in the present century.

This is an outline of the views which we have on this subject. We have nothing to say depreciatory of Mr. Bell at all, for he has real merits; but we think that this obscure mechanic did do the thing, and that he is entitled to the merit of being the first inventor.

We will take an opportunity within a few days to write a further statement and file it.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April 21st*, 1888.

I mentioned in a recent letter the fact that Boston was very much interested at the present time in an attempt to secure exclusive franchises for electrical subways. Last week that franchise was granted, the parties accepting the franchise agreeing to pay to the city all the excess of their profits over 10 per cent. on the capital actually invested. At the end of ten years, too, it is provided that the city may buy out the company, and meantime it has the privilege of constructing subways for itself, the owners of these conduits agreeing to take them up and place them in such subway at their own expense, if ordered to do so by the Board of Aldermen. It will be seen that this is a very liberal and comprehensive franchise, but I now learn, as I write, that Mayor O'Brien, of Boston, has vetoed the order of the aldermen conferring it. He says that it is illegal, and that, therefore, he cannot pass it. I do not know what is to be done in this case, but it is possible that the aldermen may pass the ordinance again over the Mayor's veto. Boston is not the only large city in this country where this question is being agitated. I hear that in Cincinnati there are several ordinances before the Local Board, most of which ask for exclusive rights from the city, and there again we shall probably see a prolonged and bitter fight.

In New York, with the coming of Spring, there is a resumption of subway work by the Board of Electrical Control; but the trouble now lies not so much in building new conduits as in getting the old ones filled. Many electrical companies refuse to have anything to do with the conduits; they will neither pay for them nor go into them, and the consequence is that the conduits are now, for the most part, lying idle. Thus the Board, with its subways, is left very much in the attitude of Marianna of the Moated Grange. Another matter electrical that is exciting a good deal of attention just now in New York is the recent award made to the Teleseme Company by the Police Commissioners for a service of police alarm boxes. Several of the disappointed competitors are claiming to be heard again. One of the commissioners denounces the vote of his fellows as a job. The magnitude of the prize at stake—the total sum to be invested reaching, it is said, about £400,000—with the opportunity of carrying on a general public service at rental, is the explanation of all the trouble and turmoil in this matter.

The bearing of gas companies towards the electric light has always been a matter of considerable interest and importance. I may be wrong, but it seems to me there is more liberality and enterprise in this respect on the part of the gas companies of America than of those in England; and the situation is somewhat paradoxical, because in England, as far as we can make out, especially from the gas journals, the electric light is anything but the success it should be, and hence is not to be feared, while in America the growth of the electric-lighting industry has been something terrific, and thus the gas people might excuse themselves for being hotly antagonistic to it. Of course here and there instances will be found of sharp conflict between the two interests, and I suppose those cases will continue with us for many years to come; but in a great many other places the *modus vivendi* has been found in a peaceful compact, or a combination of the two interests, or even by the entry of the gas company itself into the electric light field. Some idea of the extent to which gas companies have gone into electric lighting may be formed from a statement recently made by the Thomson-Houston Company, to the effect that the gas companies in this country are now operating over 6,000 of their arc lamps. Another company, the American, has always been very warm in its advocacy of combination everywhere of the two interests. Old gas men are prominent in its management, and it has supplied a very large number of lamps to gas companies. The same may be said of several of the large arc lamp producers, such as the Brush and United States Companies together. I have no doubt that

the manufacturers of arc-lighting apparatus would be sorry to lose their customers in the gas field. This use of the arc light, which has been noticeable for some time, is now being supplemented by the patronage of the incandescent, and I hear of gas companies in all parts of the country putting in incandescent plants, which in several cases are of the alternating system. It is possible that in some instances the gas companies have done this in order to keep the lighting field to themselves; but I think it safe to assume that in the vast majority of instances they have gone into electricity as a legitimate business, and in that we ought all to rejoice for the extension it gives to the field.

The chances seem to be very much in favour of the adoption of a system of electrical execution in this State. In spite of the objections raised in many quarters, including your own, the Bill providing that executions shall hereafter be carried out by means of electricity, and under conditions of secrecy, as proposed by the special commission appointed to consider the subject, passed the New York Assembly this week with scarcely a vote against it, the proportion in favour being about 10 to 1. The Bill has been hardly amended at all, and the conditions with regard to electricity remain practically intact. Knowing what you do of American journalistic enterprise, you will not be surprised to learn that several criminals under sentence of death have been interviewed as to what they think about it, and it appears that they are all in favour of electricity as a means of "happy despatch." I do not know how they have arrived at their conclusions, but they seem to take it for granted that because it is to be less revolting to the public sense it is therefore to be less painful to the person on whom the sentence is inflicted.

Another piece of legislation in this State which is of general interest is the Bill proposing to cut down telephone rates in New York and Brooklyn. The present rate in New York is 150dols. a year. This Bill fixes the maximum charges in the sister cities at 6dols. a month, and in all other parts of the State at 4dols. a month, with the provision that if the telephone is more than a mile away from the central office, 1dol. extra per month may be charged for each mile. This measure has been favourably reported to the State Senate by the committee having it in charge, but probably will not go very much further. In other States measures of this kind have been carried through, with results disagreeable alike to the telephone companies and their subscribers, and the effort in New York has already failed so often that its lack of success may be once more counted upon. These Bills are nothing more or less than what are known here in the slang of politics as "strikes," intended simply to bleed the companies or persons at whom they are directed.

An important decision has been rendered this week at Detroit in the case of a lamp trimmer who received a shock from one of the arc-light towers of the local Brush Company. The shock so upset his nervous system that he has, it is said, since been unable to work. He therefore brought a suit for 25,000dols. damage against the company. The defence was that the man had been careless, and in substantiation of this point a small electric light tower was introduced in court with which experiments were made to show that a careful man would not receive any shock. The complainant alleged that this was not a fair test of the shock he had received, as a current lost its effect when received by a person standing on a dry floor instead of on damp earth or an iron footing. The jury thereupon gave him a verdict for 10,000dols. The company in question is one of the largest and best in the country; but is understood to have adopted the practice in connection with its tower service of running two of its large arc machines in series, thus getting an unusually high electomotive force, rendering the liability to accident greater than would be the case in ordinary street service. Still, it is supposed that the men going to their work are familiar with the conditions, and therefore would adopt such simple precautions for safety as are necessary. In New York here we have recently had a sad case of accident, in which a little pedlar boy unwound a broken telegraph wire from a pole, and received at once a shock so severe that he died soon after. It has not been proved that he had any reason or right for touching the wire; but the accident goes to show how easily sometimes, with defective conditions of insulation, ordinary telegraph and telephone wires, or innocent-looking "dead" wires, may be charged with a fearful potentiality for mischief. Our companies are gradually learning the lesson that it is easier and cheaper to spend one dollar for good insulation than five times as much for compensation in case of injury to person or property. The blizzard left so many broken wires, the clearing away of which seemed to be nobody's duty in particular, and hence there has been greater liability than usual to accidents of this kind; but I think it may be safely asserted that on the whole the lines are better patrolled, and their insulation is higher than has been the case for some time past.

The prospects of electric railroads and electric power generally continue to improve, and it looks as though we shall enjoy an excellent season in this department. All the companies report themselves as very busy, and in no way troubled by lack of orders. In this city the use of motors is increasing rapidly, and would gain at an even greater rate if the facilities for obtaining current were better. I have heard of several instances lately in which motors have been asked for by persons who were not near the existing electric mains. This trouble, however, has been very quickly overcome, and it will not be long before every power user in New York will be within at least a quarter of a mile of some general source of electric current. It is reported that, owing to the growth of their business, the Daft Company, which is one of the oldest, if not the oldest, to-day in America, in the power business, will move its factory to this city. The company has now several electric railways in successful operation, and has its hands full of new work, and a number of new ones, including that at Meriden, Ct., where the Street Car Company, which lost all its animal service through a fire lately, is to replace with electricity as its sole motive power. In this city the Daft Company, or its representatives, have in regular service about 100 motors of all sizes on both sides of the city, and some of the motors have now been running very satisfactorily for three or four years. It is reported that before long the service will be improved by the erection or occupancy of a large building to be devoted specially to work of this kind.

SWEDISH NOTES.

(FROM OUR CORRESPONDENT.)

STOCKHOLM, *April* 30, 1888.

Negotiations have for some time been pending between the Swedish State Telegraphs and the Bell Telephone Company at Stockholm, with regard to the purchase of the latter. These negotiations have now, however, been discontinued, the managing director of the Stockholm General Telephone Company, who has succeeded in buying the greater portion of the Bell Telephone Company's shares, having intimated that he should oppose the sale.

The town of Vesteras will in all probability soon obtain a central electric lighting station, the gasworks of the town having under contemplation the erection of such a station. A detailed plan has been laid before them by Messrs. Luth and Rossen, electrical engineers, Stockholm, and from a financial point of view there does not appear to be any serious difficulties. To begin with, it is only the intention to supply light for indoor use, the cathedral, the college, the town hall, and several other public buildings being first on the list.

A new manufactory for incandescent lamps has been started at Stockholm, Mr. R. W. Strehlenert having removed to this town from Södertelge, where he for a couple of years has been engaged in partly preparatory work in connection with this manufacture. All the most recent improvements have been taken into account, and the Swedish lamps appear to be quite able to hold their own against foreign competition. On a recent occasion they gave great satisfaction at a ball at the Royal castle. Mr. Strehlenert has succeeded in securing an able staff of men, and is at present turning out some 600 or 700 lamps a week, which number, however, can be raised to 2,000 a week, if required.

CORRESPONDENCE.

THE "PAPERS OF FLEEMING JENKIN."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice that in your journal of the 27th inst. you review the published "Papers of Fleeming Jenkin;" therefore, perhaps you will allow me to say a few words upon the same subject.

Jenkin appears to have freely expressed his opinions on things generally, and has shown that his thoughts took much higher flights than those usually connected with telegraph engineering. My own remarks, however, shall be confined to that subject.

On page 75 of the "Memoir," in a letter dated from Birkenhead, April 18, 1858, he writes :—

"Well, you should know, Mr. ——, having a contract to lay down a submarine telegraph from Sardinia to Africa, failed three times in the attempt. The distance from land to land is about 140 miles. On the first occasion, after proceeding some 70 miles, he had to cut the cable—the cause I forget."

I do not know where Mr. Jenkin got his information; but the facts are these. In July, 1854, Mr. Brett and his then associates successfully laid a very heavily iron-bound six-conductor multiple cable from Spezzia to Corsica, and from Corsica to Sardinia. In the following year he endeavoured to continue the line with the same class of cable from Sardinia to Africa, but failed, owing to the weight of the cable, the depth of the water, the unfavourable state of the weather, and the employment of a towed sailing ship, instead of a steamer, as used in his successes. Mr. Brett consulted too many cooks, an error, if all one reads be true, not confined to electrical science, or to Englishmen, and he paid the usual penalty. Alas! poor Brett, when the history of submarine telegraphy comes to be written your name should take a prominent position among those who have helped to make it a success.

This is, as far as my personal knowledge goes, all that was done there at that time; afterwards I only have information from what I have heard and read, which it is not necessary to quote on this occasion. The letters of Jenkin referring to the work done between Alexandria and Candia are to me very interesting, and confirm my then expressed opinion that it was the eccentricities displayed by the alternate dry and wet hemp (for be it remembered there was no iron wire to control it), and not the faulty core, as stated, that caused the failure. It was useless to point out the many instances in which what is termed the core, "unprotected" either by iron or hemp, had advanced submarine telegraphy, while the blind infatuation which imagined everything else perfection, and the "beastly" core the only cause of the mishaps, did so much to retard it.

In one of these letters, on page 98 of the "Memoir," he says, "The Alexandria cable has again failed; after paying out two-thirds of the distance successfully, an unlucky touch in deep water snapped the line." In another letter, given on the following page, he says, "Once it broke inside the ship, but I seized hold of it in time, the weight being hardly anything, and the line for the nonce was saved."

It was fortunate for Jenkin that I was ignorant of these letters when we discussed those matters. I do not know what he means by "an unlucky *touch* in deep water."

At page 229 of the second volume, in speaking of the 1866 expedition, Jenkin states: "The arrangements worked as well in practice as they were admirable in theory. Fortunately no fault occurred." The fact is that fortunately a fault did occur. I say fortunately advisedly, for it proved much, giving us another instance of how well the splendid ship was under the control of Captain (now Sir James) Anderson and his officers. The big ship moved like a thing of life endowed with reason, and seemed fully to enter into the hopes and fears of all concerned. My system of electrical arrangements, which I had adopted for ship and shore, proved to be perfect, and enabled the fault to be thoroughly examined at our leisure. The fault developed itself at 6 a.m. The "Great Eastern" was immediately stopped, the cable cut in the tank a few turns from the sea portion, and the fault found to be in those turns. A section coiled in another tank was spliced on to the sea portion, and before 8 a.m. paying-out was resumed, and all was working as before, continuing to do so until success crowned our efforts.

In the unsuccessful expedition of 1865 I was almost "sent to Coventry" because I would not embrace the "malice" theory, to account for the fault which occurred during the submersion of 1,200 miles of that unfortunate cable. I then firmly asserted my belief that the hemp concealed a break in the wire, which it enclosed, and that the broken wire being bent in coiling, penetrated the hemp and gutta-percha of the coil beneath it.

That being the case in my opinion, I took care when we had at last caught a fault to carefully investigate it, more especially as it occurred in a portion of the cable which it had been intended to lay in the previous year, and consequently it had been coiled on board the "Great Eastern" and passed as good for 18 months. By careful manipulation the fault was found to be caused by the one end of a broken wire in one of the uppermost laps getting bent, and entering the gutta-percha of the lap immediately beneath it, the tread of the "cable hand" over it being sufficient to press the wire to the conductor. No doubt the faults of 1865, which led to such a disastrous termination, were caused in this way.

Now that I am on my hobby I should like to ride it further, did not the fear of trespassing upon your space oblige me to refrain from so doing.—Yours, &c.,

April 30th, 1888. WILLOUGHBY SMITH.

ALTERNATE-CURRENT TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue Prof. Perry is reported to have said, in the discussion of a Paper by Mr. Sumpner at the Physical Society, that I had asserted that the ripples in an alternate current are increased by a transformer. Allow me to correct this. I never made such an assertion, nor did I take any part in the discussion of the subject when it came before the Society of Telegraph-Engineers. I remember the statement being made, and I was at the time rather surprised at its being discussed seriously, as it seemed to me that it must be against the nature of inductional action to do anything of the kind. I should as soon have expected a hose-pipe to increase the pulsations in a stream of water flowing through it.—Yours, &c.,

London, S.E., May 1, 1888. W. M. MORDEY.

[We learn from Prof. Perry that he mentioned the name of Mr. Evershed, not Mr. Mordey.—ED. *E.*]

SELF-INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In response to Dr. Lodge's letter I beg leave to state that the report of my Paper on "The Variation of the Coefficient of Induction" is only a brief summary of the general conclusions arrived at. The experimental part of the Paper, which forms by far the greater portion, is omitted in the abstract.

The statement to which Dr. Lodge more particularly refers can easily be verified mathematically. If a condenser of capacity K, charged to a potential V_0, have its terminals connected by a wire of resistance R, and having a coefficient of self-induction L, the potential of the condenser at any subsequent time t, will be given by one of the following equations:—

$$(1) \quad \frac{V}{V_0} = \frac{T_1}{T_1 - T_2} \epsilon^{-\frac{t}{T_1}} - \frac{T_2}{T_1 - T_2} e^{-\frac{t}{T_2}},$$

$$(2) \quad \frac{V}{V_0} = e^{-\frac{Rt}{2L}} \left(\frac{\sin(\alpha t + \beta)}{\sin \beta} \right).$$

The first equation is to be taken when L is less than $\frac{K R^2}{4}$ and the second when L is greater than this value.

In the first equation T_1 and T_2 are the two quantities whose sum is K R and whose product is K L. Both quantities are positive, and T_1, the larger, is necessarily less than K R. The potential V will depend chiefly on

Digitized by Google

the values of the exponentials $e^{-\frac{t}{T_1}}$ or $e^{-\frac{RT}{2L}}$. If it is allowable to neglect the quantity e^{-10} in comparison with unity, the condenser may be regarded as completely discharged in a time $10\,T_1$, if L is less than $\frac{1}{4}$ K R², and in a time $10\,\frac{2\,L}{R}$ if L is more than this value. As these quantities are each less than 10 K R, provided L is less than $\frac{1}{4}$ K R^2, it follows that for such values of L the discharge will take place more rapidly in consequence of the presence of self-induction in the circuit.—Yours, &c.,

W. E. SUMPNER.

Central Institution, Exhibition-road, London, S.W., May 2nd, 1888.

D'ARSONVAL'S GALVANOMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to point out that the galvanometer designed by Dr. A. D'Arsonval, of which you print a description, translated from *La Lumière Electrique*, in your issue of the 13th inst., is by no means the proportional reading instrument which its inventor assumes it to be. I say assumes because I do not think he can have made any accurate experiments with it. Obviously, if the instrument is to be a proportionally reading one, the magnetic field in which the conductor moves must be uniform; and this a glance at the sketches will show is by no means the case in the instruments described, and also that it would be a very tedious and difficult matter to proportion the distances and varying thicknesses of the cylindrical pole-pieces so as to obtain a uniform field.

Why it is not necessary for Dr. A. D'Arsonval to say that the instrument is absolutely dead beat is quite past understanding if he wants anyone to think it is so; but one feels glad he is not at the necessity of saying what would be manifestly inaccurate. Dr. A. D'Arsonval has no doubt displayed considerable ingenuity in the design of his galvanometer, and a useful instrument might be made on similar lines.—Yours, &c.,

Lisbon, 19th April, 1888. W. B. SAYERS.

LIGHTNING PROTECTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With regard to your notes on the damage done to instruments by lightning at Porthcurno on the 14th February, I think many of your readers would be glad of fuller information. I, for one, am at a loss to know what did actually happen. It would appear that the damage was caused by a direct lightning discharge—a very unusual occurrence.

With regard to the Siemens plate protector, I think it has been for many years recognised that this, although affording absolute protection to a submarine cable, is hardly sensitive enough to prevent the fusion of such delicate coils as those of the recorder.—Yours, &c., EDWARD STALLIBRASS.

25, Great George-street, April 28th, 1888.

[With regard to our note on the "Saunders" lightning protector in connection with the incident referred to, we gave the name of the inventor as Mr. W. Saunders instead of Mr. H. A. C. Saunders (of the Eastern Telegraph Company). We should be pleased to receive from Porthcurno the further details for which our correspondent inquires.—ED. *E.*]

ELECTRIC GAS LIGHTER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have a static induction gas lighter which is at present out of order through the want of new collecting brushes. Would some of the readers of your valuable paper kindly tell me where I may obtain exceedingly thin metal, similar to that used for the collecting brushes of the above kind of gas lighter? Trusting I am not asking too much.—Yours, &c., R. H. W.

[In reply to the above query, a correspondent writes as follows:—"Smith and Son, St. John-street-square, Clerkenwell, or Harrison, of Drury-lane, would be the most likely places. If they have none thin enough he could get some rolled down on purpose at Knight's Flattening Mills, Clerkenwell-close."]

RESISTANCE COILS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I note that my letter, as printed in your issue of April 13th, has one error which, perhaps, it is worth while to call attention to. It reads, "and in case of 10-ohm coils the difference is a very considerable percentage of the whole." It should be, "in case of one-tenth ohm coils, the difference," &c.—Yours, &c., WM. A. ANTHONY.

April 23, 1888.

LONG-DISTANCE TELEPHONY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I shall be glad if you can find space in your valuable journal for the following information under the above head:—

Through the courtesy of Mr. H. F. Jackson, of the National Telephone Company, I recently had the pleasure of speaking over the Sheffield to Manchester and Liverpool trunk line, distance 144½ miles. Only 35 to 40 seconds elapsed before I was in direct communication with Manchester, and after finishing conversation I was switched on to Liverpool in about the same space of time. To both places the conversation was carried on just as easily as if we were only a mile distant. I was also in communication with Leeds and Bradford in similar time. I marked the easy and rapid manner in which the switching was carried out to each town. Having been district manager for the National Telephone Company's Nottingham division for a period of seven years, I can speak from experience upon this subject. I failed to find the slightest interruption from induction influence. I understand that the longest trunk line in Great Britain is from Sheffield to Fleetwood.

As soon as Sheffield is in communication with Nottingham—and this line is now being built—the distance from Nottingham to Liverpool will exceed 200 miles as the line will run. Birmingham is also being connected with Nottingham and with Sheffield and North Yorkshire *viâ* Derby and Chesterfield. Such communication to these important centres must be a great boon to the commercial community generally. I may also mention that the service from Glasgow down the West coast and to the Scottish capital is most excellent.

A few weeks since I also had the pleasure of speaking over a long trunk line of the Western Counties Telephone Company, by the kind permission of Mr. H. F. Lewis, the general manager, Bristol, between that ancient city and Llanelly, South Wales, distance 128½ miles, including a cable across the Severn Bridge. Particulars of towns and distances are given below. I was in communication with Swansea within one minute, when, after conversation, I was asked to be switched on to Llanelly. This occupied about 45 seconds. The communication was perfect in every respect.

Mr. Lewis states that the longest distance spoken by them is from Bath to Llanelly, a wire mileage of 142½ miles. The speaking was in every way perfect and commercially good.

I must not forget also that I had the same pleasure extended to me by Mr. C. B. Clay, the General Manager of the Northern District Telephone Company, Sunderland, whose trunk-line system I also give below. I found the switching similar in space of time as over other systems. I failed to observe any induction over any section of the trunk lines, which are erected on the twisted metallic circuit system. The wires in Yorkshire and Lancashire, however, are all single, and at the time of my trial were perfectly quiet, though I am informed that there is generally some induction disturbance, though so slight as to be of no practical consequence.

While speaking between Sunderland, Newcastle, Middlesborough, Darlington, and intermediate stations, a heavy thunderstorm was reported from these stations; but no interruption was observable, and the conversation, switching, &c., was carried out without the slightest difficulty.

The National Telephone Company for their local exchanges for the past five years or more have used bronze wire, manufactured by the Phosphor Bronze Company, Sumner-street, Southwark, London, and similar wire is now, and for some time past has been, exclusively used by the Western Counties, South of England, and Northern District Companies for local

services, and I understand has given unvaried satisfaction, it having great tensile strength, resistance to oxidation and elongation. After a heavy fall of snow or other strain on the wire, it recovers its normal position, which copper or other wire fails to do; and consequently where copper wire is used the cost of maintenance is much heavier, apart from the inconvenience caused to subscribers by the lines being frequently interrupted. As the so-called hard-drawn copper has simply a mechanical strength, being erected in long spans, such as it is impossible to prevent in towns, it gradually loses its strength, whereas bronze wire, after being erected years, remains the same. Mr. Preece's Paper on "Electrical Conductors," read before the Institution of Civil Engineers, on 4th December, 1883, touches upon this point, extract of which is given below.—Yours, &c., JAMES O. FRY.

INSULATION FOR ARMATURE WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to ask which is the best insulation for armature conductors after being double-cotton covered?—Yours, &c.,

10, West-street, City-road, Bradford, Yorks, E. BENN.
April 17, 1888.

[It is a little difficult to say which is "the best" material for this purpose. Several firms keep the composition of their varnishes secret, but any good india-rubber varnish may be expected to prove satisfactory, at any rate for low tensions.—ED. *E.*]

ELECTRICAL LIFEBOATS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Electrical power is looked forward to as the agency for lifeboats in the near future. The Council of this Exhibition has two handsome money prizes to offer for the best lifeboats, steam, electrical, or rowing, and we think that some of your readers might be able to exhibit some electrical machinery well adapted to propel lifeboats against adverse winds and tides. The prizes alluded to are the gift of the proprietors of "Cherry Blossom," and no doubt others will come forward for so humanitarian a purpose as saving life from loss at sea, which amounts to something approaching 5,000 each year.—Yours, &c.

F. JOHNSON, Manager,
International Maritime Exhibition.

Alexandra Palace, April 25, 1888.

ART GALLERIES LIT BY ELECTRICITY.

A correspondent asks us to furnish a list of the Art Galleries in the United Kingdom which are lit by the electric light. The following are all that occur to us at the moment, and we shall be glad if our readers will enable us to make the list complete:—

South Kensington.
The Grosvenor Gallery.
Institute of Painters in Water Colours.
Birmingham Corporation Art Gallery.
Hastings.

At the Liverpool Gallery, we believe, the light has been discontinued.

TELEGRAPHIC COMMUNICATION WITH THE PHILIPPINE ISLANDS.

The following is a translation of an article which recently appeared in the Spanish journal *La Paz*:—

"In a limited article like this it is impossible to deal properly with such a wide question as the necessity for submarine cables in the Philippine Archipelago. However, when we mention that not a single cable is in existence as a means of communication between island and island nothing that is said can seem out of place. During the last few years several grave events which have occurred in these distant islands have forcibly demonstrated the tremendous inconvenience of the non-existence of rapid modern means of communication. Not only was His Majesty's Government in the dark, but the very Colonial officials themselves lived in ignorance of what was taking place in the far distant corners of the Archipelago. This state of things still exists, as we have but recently seen. Under such lamentable conditions good government is impossible. The general torpor engendered by such slow means of communication results in every occurrence coming as a bolt out of the blue; all remedies come too late, all public and private enterprise is stifled. If we have cited a few of the reasons why the Government should have cables laid, we must not forget the urgent needs of those interested in the commercial prosperity of the islands. The necessity for promptly laying submarine cables is so obvious and so generally admitted that it seems superfluous to enlarge upon the theme. What prevents the realisation of this idea? Is any private interest or privilege menaced, explaining though not justifying this delay? Not one! Is it that the exchequer of the Archipelago is unable to bear the expense of a cable? Certainly not; let the word be spoken, and the cable will be laid. Well, but there is something explaining this eternal delay. Yes, the baneful and terrible slowness of all official reports, travelling as they do from Spain to the Philippine Islands, then home again, and once more back to the East to be examined here and out there by governmental, financial, technical, consulting authorities, &c.

"A few years ago some of the irresistible arguments set forth above caused the Government to think of having a cable laid down between Manila and Zolo, in order to connect the isolated and distant isles of the Archipelago; for isolated they are, in spite of their proximity to one another. The cable mileage requisite is some 700, distributed as follows:—200 from Luzon to Cebri, touching at Panay and Negros; 300 from Cebri to Zamboanga (Mindanas); 100 from Zamboanga to Zolo. The cost of a nautical mile of cable may be reckoned at £220, which was the contract price for the Hong Kong-Luzon cable. Time has shown that the choice made by Señor Eldnazen in the Royal decree of the 22nd Feb., 1879, was a most judicious one. The company chosen is the only one possessing telegraph ships in those regions, ready to repair at a moment's notice any injured cable, besides which it had already more than 50,000 miles of cable at work in 1879. This company, whose position defies competition, was then and is now the only possible one. This company could lay the necessary cables in a very short space of time, dispensing with the official investigations, which are almost as costly as the cables themselves. The cables could be laid by the trained staff of the company from its own telegraph ships; everything, in short, would be done, once and for all, gratuitously and economically for the State. The same clauses relating to the free transmission of Government messages, &c., inserted in the case of the Hong Kong-Luzon cable, could be insisted upon now, and the desired object attained directly. Nevertheless we are sadly afraid that the cable will, as yet, only be laid down in official documents. And this will be so, not because Señor Balaguer is lacking in affection for the Philippines, but because we fear that he himself is now getting enveloped in the fatal meshes of bureaucracy, which strangle the best intentions and render the grandest ideas sterile."

PRIESTMAN'S PETROLEUM ENGINE.

Messrs. Priestman Brothers are exhibiting at their show room, 73A, Queen Victoria-street, a new petroleum engine, which is driving a dynamo for electric lighting. A larger engine of the same type, about seven or eight horse-power, is working at the Electrical Power Storage Company's Works, Millwall, charging accumulators.

This engine uses only the ordinary petroleum of commerce, and is therefore free from the objections raised against the use of engines employing highly inflammable spirits, such as benzoline and gasoline.

It is very simple in construction, having few working parts. The oil from which the motive power is obtained is placed in a closed iron tank inside the foundation; air is pumped into the tank until

Digitized by Google

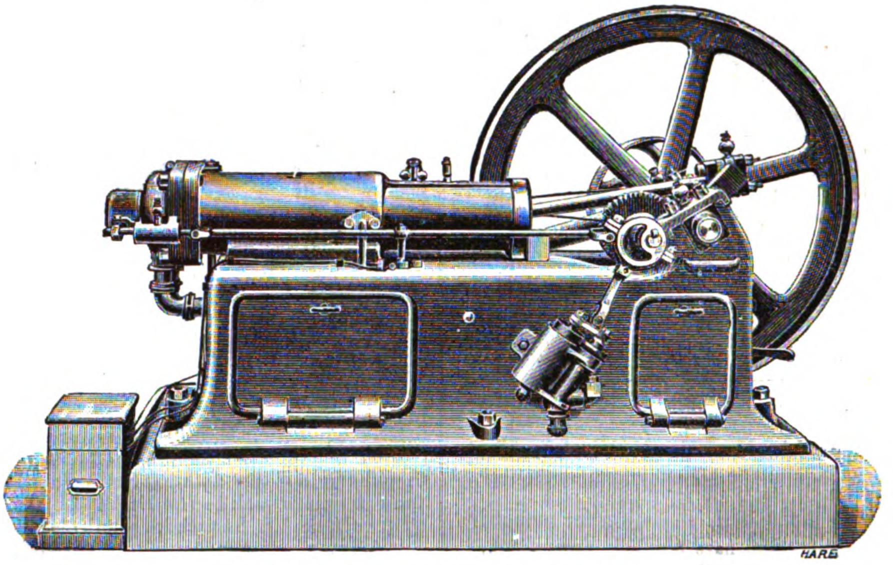
a pressure is obtained of about five pounds to the square inch. The oil is then mixed with air until it is formed into a vapour, after which it is passed into a closed iron vessel or vaporiser, where it is heated, and from which it is admitted into the cylinder, and ignited by means of an electric spark, which is obtained from a small primary battery. An explosion is obtained at every second revolution. The battery is capable of doing about 30 hours' work without attention, but we think that the makers would find a small magneto machine more convenient for the purpose.

To start the engine it is only necessary to heat the vaporiser for a few minutes, and take a turn or two of the fly-wheel, after which the required heat is obtained by utilising the heat from the exhaust products.

engine requires no coal or gas it can be fixed and worked where other motors could not be employed.

The great difficulties to be overcome in perfecting a reliable engine using only common petroleum oil have long been recognised, but judging from what we have been able to learn of its performance in the hands of independent users there seems to be every reason to believe that those difficulties have at length been successfully overcome.

There is a special opening for a motor of this kind for electric lighting in country places where gas is costly or not obtainable, little progress having been made hitherto in introducing the electric light in districts where it is most required, for lack of a suitable motor.



PRIESTMAN'S PETROLEUM ENGINE.

The cost of working this engine, taking oil at the present price, is said to be a little more than ½d. per indicated horse-power per hour.

No driver is required, there is of course no boiler, and as the

No extra charge is made for insurance, &c., where this engine is placed, and no license is required, as in the case of an engine using inflammable oil. The safety of using this oil is proved by the fact that a lighted match may be thrown into it without causing ignition.

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The twenty-ninth ordinary general meeting of the shareholders in this Company was held on April 25th, at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting, and the minutes of the last meeting, which were approved by the present meeting, and signed as correct by the Chairman. The report of the Directors was taken as read.

The CHAIRMAN: I shall, as has usually been my custom, go over some figures in the report, so that I may give you the opportunity of putting any questions and getting such explanations as it has always been my pleasure to give you. The gross receipts for the half-year have amounted to £232,660, against £216,956 for the corresponding period of 1886, or an increase of £15,704. The working expenses for the half-year amounted to £69,570, against £80,066 for the corresponding period of 1886, showing a decrease of £10,496, which is mainly due to the cost of repairs to cables being lighter during the past half-year than in the corresponding period of 1886. The net revenue for the half-year amounted to £117,889, against £91,070 in the corresponding period of 1886, showing an increase of £26,819. Comparing the figures for the whole year, the results are as follows:—Gross receipts in 1887 £451,861, against £441,799 in 1886, showing an increase of £10,062. The working expenses in 1887 were £145,812, against £161,841 in 1886, showing a decrease of £16,029. One interim dividend of 1¼ per cent. has been paid for the half-year, and it is proposed to pay another of like amount to-morrow, making, with the interim dividends for the first half-year, a total dividend of 5 per cent. It is also proposed to distribute a bonus of 3s. per share, which will make a total payment of 6½ per cent. for the past year, against 6 per cent. for the previous year. The balance of £53,051 has been carried to the general reserve fund, which now stands at £620,095, as shown by the following figures:—Amount of fund at end of 1886 £569,440, interest added during the year £20,363, balance of revenue £53,051, making a total of £642,854, from which has been deducted the cost of a further partial renewal of the Singapore-Saigon and the Penang-Rangoon cables £22,759, leaving a balance of £620,095. The net result, therefore, of the past year's working is that the reserve fund has been increased by £50,000; the further partial renewals of the Singapore-Saigon and Penang-Rangoon cables have been paid for out of revenue, and 6½ per cent. distributed amongst the shareholders. Now, gentlemen, I think you will agree with me that that is a very satisfactory statement to put before you to-day, and when I tell you that we have recouped ourselves to a considerable extent the reductions in the tariff which we made at the Berlin Conference, I think the position of the Company may be said to be as prosperous almost as we could fairly expect it to be. There is a feature in connection with our large reserve fund that I should like to point out. We had a suggestion, by the way, from one of our shareholders, that we should re-value our securities and pay the excess over the original cost as a bonus to the shareholders. I must say that while I am always pleased to pay bonuses when we can do so with some reason, I am afraid that there would be no good reason for paying a bonus out of the premiums shown on the re-valuation of the securities in which the reserve fund is invested. As an illustration of that, I may mention that a month or six weeks ago the increased value of those securities was something like £75,000; but if we had paid that £75,000 away I am afraid we should have required to ask

you to refund it, because the extreme prices which enabled us to show that premium were more or less the result of the change that was taking place owing to Mr. Goschen's scheme for the conversion of the National Debt. That caused a rush for other securities, and the result was that there was a very considerable increase in the prices. Still, to-day there is the substantial sum of £50,000 profit on the securities in which our reserve fund is invested. There is another good feature that I am pleased to bring before you, that further drawings of the Company's Five per Cent. Debentures have taken place since the close of the half-year, and the capitals outstanding have thus been reduced as follows:—The original £100,000 of the Five per Cent. issue of 1880 has been reduced to £24,400, and the £640,000 of Australian Government Subsidy Five per Cent. Debentures have been reduced to £446,000 by annual drawings. Therefore, while we are increasing the reserve fund we are decreasing our capital liabilities. The question of cable renewals is also one which requires a good deal of consideration. The completion of the renewal of the Singapore-Saigon section with brass-ribboned cable has been carried out since the close of the half-year, the cost of which, amounting to about £17,000, will be dealt with in the accounts for the current half-year. This gives us a new cable, entirely brass-ribboned, between Singapore and Saigon, paid for out of revenue. Therefore, you see, we are strengthening our position in every way; we are strengthening our power of carrying on the work; we are strengthening our position as a Company to defy almost any competition; and I believe the only way to maintain the position which we occupy at the present moment is to do our work better than it would be possible for any other company to do it. During the coming year we have still important work to carry out. We purpose effecting important alterations in the Madras-Penang cable at the Nicobar Islands, and in the Java-Australian cables off the Lombok Strait, where we have frequently had difficult and costly repairs. These changes will probably cost £75,000, but it is anticipated that they will effect considerable improvement in the working, and a large saving in the cost of repairs. If we had our cables laid on such ground that no repairs were required, we should be able to pay a very much larger dividend than we are now paying, but the cost of maintaining the cables is a very serious item in our accounts. As, however, I have said before, we have duplicated most of our cables; and at the same time we have not to any great extent increased our capital. This duplication of our cables gives us such security in carrying our traffic that you never hear, or scarcely ever hear, of any interruption in our telegraphic communications. That is the real source of our strength, and that we shall endeavour to maintain as long as we have the confidence of our shareholders. I have mentioned on one or two occasions the difference we have had with the New Zealand Government in regard to the renewal of their subsidy. I dare say you have all observed in the papers that the financial condition of that colony has not been as prosperous as we would wish to see it or as its friends would wish it to be. New Zealand has a grand future, but at the present time they have probably spent a little more money than was prudent. Probably it would have been better had they spread the expenditure over a longer period. Nevertheless, the work is done, and it will help materially in developing New Zealand, and I have no doubt that before long we shall see the colony in the prosperous position she once occupied. At the same time it has made her very careful in her expenditure, and the result has been that the Ministry did not feel disposed to put before their Parliament the question of renewing their subsidy. Consequently, we had to take the next best course, and increase our tariff so as to recoup us to some extent for the loss of the subsidy. That measure shows the importance of our system. Notwithstanding the increased charge we made—which, I may say, was not much objected to on the part of the New Zealand Government—we have had an increase in the number of words over our cables, showing that telegraphic communication has become an absolute necessity. The result has been that we have nearly recouped the loss of the subsidy out of the traffic at the increased tariff. The next question that may interest you is in regard to our relations with China. When I had the pleasure of addressing you six months ago I mentioned that we had been negotiating with the Chinese Government, and that the negotiations were practically finished. The agreement is, however, still unratified by the Central Government; but the Chinese never move very quickly, and we are perfectly satisfied to wait their pleasure, as by waiting we are enabled to put money into our own exchequer which we should otherwise have to pay to the Chinese. We have also heard a good deal about opposition in the Pacific. That may come some day. I never say that anything is impossible. They have now decided to take soundings, which will probably extend over a period of three years, so that for that time at least we shall not be troubled with an opposition line viâ the Pacific. Should the question arise again, I hope that our position will enable us to deal with it in such a way as will not make it possible, or, at all events, possible in any way to annoy or inconvenience us. There is another matter I think it is right you should know, as we are always anxious to give our shareholders the fullest possible information. Western Australia, though not one of the leading colonies, is very anxious to have direct communication with this country, and the Government of Western Australia have received an offer from some of their people to help them to attain that end. We are equally disposed to take this view, if it is necessary; and if we find that we can carry it out with advantage to them and to ourselves, we shall not lose sight of it. We are at the present moment looking into the question, and possibly when I meet you some months hence I shall be able to tell you that we have made some arrangement with that colony. Since I last addressed you we have completed an arrangement with the Netherlands-Indian Government for a cable of 462 miles between Java, Baly and Macassar. They pay for the cable, and it will be a feeder to our system, and with that object in view we have done everything we possibly could to assist them. I have one more duty to fulfil, and that is to express the great regret of the Board at the death of one of its colleagues, Sir William M'Arthur. He was associated with this Company from its inception, and was a most useful member of the Board. He was well known not only in the colonies, but also at home. He was a thorough man of business, and was constantly doing good works. With these remarks I beg to move:—

"*That the report and accounts of the Directors now submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 3s. per share, both free of income-tax, payable on the 26th inst., making, with the previous distributions, a total payment of 6½ per cent. for the year 1887*"

The Marquis of TWEEDDALE: I have great pleasure in seconding the motion.

The CHAIRMAN: If any gentleman has any remarks to make I shall be glad to hear them. No one rising to address the meeting, he put the motion in the usual way, and declared it carried unanimously. Continuing, he proposed the following resolution:—

"*That John Denison Pender, Esq., who now retires by rotation, be and is hereby re-elected a Director of this Company.*"

Sir JAMES ANDERSON: I have much pleasure in seconding that.

The CHAIRMAN put the motion in the usual way, and having declared it carried unanimously, added: I may say that Mr. John Denison Pender is my son, and I am anxious that I should have my son following to some extent in the footsteps of his father. I am getting on in life, and I desire my son to know thoroughly the wants and the duties of a concern like this. Although he is a comparatively young man, yet he is very much older than I was when I took much more serious responsibilities on my shoulders than I have even at the present time. I am pleased that you have accepted my son in the place of the late Sir William M'Arthur, and I only hope that he will prove equal to his duties. If he does not he is now taking a position in which he must be judged by his own merits.

Mr. J. D. PENDER: I beg to thank you, gentlemen, for electing me a Director.

The CHAIRMAN: The next resolution is

"*That the Most Hon. the Marquis of Tweeddale, who now retires by rotation, be and is hereby re-elected a Director of the Company.*"

Lord Tweeddale has been with the Company from the beginning. He is one of the band of men who have worked earnestly and honestly in the promotion of submarine telegraphy; and, as I have said before, when the history of submarine telegraphy is written, Lord Tweeddale's name will be associated with it as one of its principal promoters.

Mr. BEVAN: I have great pleasure in seconding the motion—which was carried unanimously.

The MARQUIS OF TWEEDDALE: I beg to thank you, gentlemen.

Mr. VARLEY: I have great pleasure in proposing

"*That Mr. Henry Dever and Messrs. Quilter, Welton and Co., be and are hereby re-elected auditors for the ensuing year, at a remuneration of £100 each.*"

Mr. KING: I beg to second the motion—which was carried unanimously.

The CHAIRMAN having intimated that that closed the business of the meeting,

Mr. VARLEY said: I think the least we can do is to move a vote of thanks to the Chairman and the Directors for their services. They have presented us with an admirable report. The Chairman anticipated one of the remarks I had intended to make as to the immense increase in the value of the reserve fund. He mentioned also that there had been a little falling off, but I have no doubt that that will be recovered again. I do not believe that leading debenture stocks will ever go back to the prices at which they stood a short time since. Our Six per Cent. Debentures fall in in a few years, and I think we shall gain by that something like £6,000 a year in replacing them.

The resolution was seconded, and carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself, I return you our most hearty thanks for your continued support and appreciation of our labours. I really feel that our Company is in a very healthy position, and looking at the fall in securities in many directions, I think that it affords a very fine investment indeed, because we are now demonstrating that it *is* a property. Although it is at the bottom of the sea we can keep it in constant working order, and in a position to earn a good dividend; and it will be our duty, as it will be our pleasure, to continue to pay you as large a dividend as we can.

The meeting then terminated.

The London Platino-Brazilian Company (Limited).

An extraordinary general meeting of shareholders of the Company was held at the offices of the Company, Winchester House, Old Broad-street, London, E.C., on Friday, the 27th April, 1888, for the purpose of considering and, if deemed desirable, passing a resolution approving an agreement, dated 18th April, 1888, entered into by the Directors of the Company with the Western and Brazilian Company (Limited), and authorising the Directors to carry the same into effect. Sir John Pender, K.C.M.G., chairman, presided.

The CHAIRMAN said: Gentlemen, the secretary will read the notice convening the meeting.

The SECRETARY (Mr. William Payton) having read the notice,

The CHAIRMAN said: Gentlemen, this being an extraordinary general meeting, called for an express purpose, I will call upon the solicitor to read the agreement which in the few remarks I intend afterwards to make I shall recommend for your acceptance.

Digitized by Google

The SOLICITOR (Mr. Norton) having accordingly read the agreement,

The CHAIRMAN said: Gentlemen, you have heard the agreement read, and I shall now read the resolution which I have to propose, after which I shall make some remarks on the present position of the Company and lay before you the reasons which have induced the Board of this Company to bring this proposition before you and recommend it to you for acceptance:—

"*Resolved, that the provisional agreement, dated the 18th day of April, 1888, made between the Western and Brazilian Company (Limited) of the one part and of the London Platino-Brazilian Company (Limited) of the other part be, and is hereby, approved, and that the Directors are hereby authorised to do all things necessary to carry the same into effect.*"

Now, gentlemen, before I put the resolution to the meeting I think it is right that I should recall to your memory the history of this Company and the reasons which brought the present Board of Directors into existence. They did not solicit that honour, but they were appealed to by certain shareholders largely interested in the undertaking, which had been brought into a state of chaos, paying nothing and doing nothing, to take it by the hand and endeavour to bring it to something like the position which it ought to occupy among the submarine telegraph systems of the world. We took it up. Captain Pavy and myself took a very prominent part in the formation of the Board, and we called in the very best assistance in our power to carry out the work, and here let me say we could find no better man, and there is no better man to be found to-day, than our friend and colleague, Mr. Hollocombe. The result has been that we have saved this Company from wreck and ruin, and we have brought it into a position in which it is able to make fair and honourable terms with another larger and more powerful company. My experience of submarine telegraph companies teaches me that a small company standing alone can be beneficial neither to itself nor to the public generally, and certainly it cannot be of the same value to its shareholders. The less friction that there is in telegraphy the better. That applies not only to the system of working, but also to the boards. It is not for me to condemn the first agreements that were made by this Company with its promoters and projectors, and the agreements afterwards made with the Western and Brazilian Company. We all know that lawyers sometimes differ, and the lawyers somehow or other, when they made these agreements, did not foresee the difficulties that might arise in the future. That is one of the reasons—not the most important—but that is one of the reasons that has induced your Board to consider whether it is better, not that it should be absorbed, but that the control of this Company should pass into the hands of a larger and more powerful company. Why should we go into a court of law and fight all our points of difference, so as to establish what I may call a proper understanding between the two companies? The Boards of both companies are gentlemen well known to one another. We dislike the law, but we see that recourse to law is absolutely necessary if we continue to work apart (applause). Upon these grounds, gentlemen, we consider it desirable that the two companies should be brought under one control. It is not a question of amalgamation—it is simply a question of our handing over the control of this Company to the Western and Brazilian Company. We shall have practically nothing to do with the management. We are now entitled to a certain percentage—20 per cent. of the gross rates—but they can so manage that they can make that 20 per cent. just what it suits their own convenience and their own interests. (A VOICE: "How?") Because they are entitled, for instance, to make a bargain as to a reduction of rates. They benefit by that reduction of rates. It tells against our interest, but it does not interfere with theirs. It is a point to consider whether in equity that is a fair and a just thing, and might involve us in a lawsuit to establish the particular point. If anyone will take the trouble to read over the original agreement he will find in it the finest matter for a troublesome lawsuit that I have ever seen in my life. We want to avoid law, and we have brought the thing exactly into this position, that those who wish to cling to the old Company can remain with the old Company, and those who desire to let the concern go into the management of a larger company can do so. I have now to point out to you the advantages of the scheme. And, first, let me observe, gentlemen, that I am bound to say, watching it as I have done, that the management of the Western and Brazilian Company has been such as to raise it very considerably in my estimation during the last few years, and therefore I see in the future of that company more power and more profit. It is for that reason that I do not hesitate to recommend to the shareholders of this Company to take three shares of that company for five shares of this Company. The result will be that there will be something like 1 per cent. more in dividend than you are likely to receive from this Company. These are the reasons why we ask you to accept this exchange. I do not press it upon you. I am personally perfectly satisfied to go on and work as we are. I am a considerable shareholder, but I feel, being largely connected with submarine telegraphy, that the more the management can be concentrated the better it will be. I am not going to talk to you as if your property was not as good as theirs. I am not going to tell them that their property is much better than ours; but what I say is that by managing the two companies together we shall make more money than can be done by managing them separately. These are my reasons, and I need not go into further details, for recommending this scheme to you. I am quite willing to explain to anyone anything further; but I think I have said sufficient to show you that the platform on which we now stand is one that justifies us in bringing the scheme before you by which we shall make a bargain which we consider will be equitable and fair to both companies, and which we believe will not only promote the interests of telegraphy generally, but will more particularly add to the profits of the shareholders of the Platino-Brazilian Company. With these remarks I beg to propose that the resolution which I have just read be approved.

Captain FRANCIS PAVY seconded the resolution.

Mr. YOUNG desired to know how it was proposed to deal with the uneven numbers of the shares. He wished further to ascertain what would happen to these shareholders who did not signify their intention by the 20th May of agreeing to the schemes. Were the staff of the Company to be taken over by the Western and Brazilian, and were any of the members of the Board going on to the Board of the other company?

The CHAIRMAN: None of the Directors of the present Board go over to the other Board; I may also say the same thing with regard to the staff.

Mr. YOUNG thought the proposed arrangement was one that should meet with the approval of the shareholders, seeing that by their exchanging five of their shares for three of the Western and Brazilian Company's, there was an advantage of £1 in favour of the Platino-Brazilian shareholders. With regard to law expenses, he detested lawyers, and as the Chairman had pointed out, if they could reconcile two companies that were to a certain extent antagonistic by adopting such a course, he thought it to be in the interest of all concerned to do so.

Mr. FRY, while endorsing everything that had been said with regard to the advisability of the Company being merged into the Western and Brazilian, begged to protest in the strongest possible manner he could against the item of £6,000 which it was proposed to pay the Directors by way of compensation. He had considered the matter over with his friends, and they failed to see any reasonable argument for allowing so large a sum, inasmuch as the Board had been very well paid for the services they had rendered to the Company. He hoped to hear before leaving the room that the Directors were willing to make some modification in the sum proposed to be paid to them.

Mr. GRIFFITH said, in reference to Mr. Young's statement deprecating their having anything to do with lawyers, that he unfortunately belonged to the legal profession (laughter). But it must be borne in mind that there were two species of law—litigation and non-litigious law. Let them avoid litigation by all means if they could, and rather take an honourable compromise when it was proposed than have recourse to it. He did not wish to criticise the agreement in detail, but he questioned whether the shareholders did not incur a serious responsibility in accepting it, because so recently as last year three of the judges in the Court of Appeal endorsed an opinion expressed by Lord Justice Lindley, while still a barrister, to the effect that shares could not be issued at a discount without laying on the shoulders of the holders the onus of being liable to pay, in the event of any future litigation, a call for the full amount of the shares, an obligation which he for one did not feel inclined to undertake. He referred also to another lawsuit in support of this contention. The saving point in the agreement was that they could retain their old shares without entering into the proposed arrangement; but, on the other hand, they lost the able services of the present Directors, inasmuch as the whole management would be transferred to the hands of the Directors of the Western and Brazilian Company, which, to his mind, was a very serious matter.

Mr. WM. FORD said that he had read the cases referred to by Mr. Griffith, and maintained that they were in no sense applicable to the present one. This was not an issue but an exchange of shares at their full value, and therefore he said with the utmost confidence that the shareholders incurred no future liability by way of a call.

The CHAIRMAN in reply, said that with regard to the odd numbers of shares, they would be dealt with either by shares or by money. If three-fourths of the shareholders did not agree to the scheme it naturally would fall to the ground, but judging from the proxies they held and by feeling the pulse of the parties interested, the Directors had no doubt whatever that it would be carried out. Mr. Ford had completely answered Mr. Griffith's objection. This was an exchange and not an issue of shares at all. They had a chance either of remaining in the old Company and seeing their dividends getting visibly smaller, or of entering into the new company and seeing them beautifully increasing. Coming to the point raised by Mr. Fry, he held that the Directors saved the concern from wreck and ruin; that they had made a good bargain for the shareholders by the proposed agreement, and that they handed over the Company to another body of shareholders without asking them to pay a penny for the transaction, because the Directors of the Western and Brazilian Company were prepared to forego their honorarium until the £6,000 compensation was paid off, and therefore, in reason and fairness, the Board were fully entitled to the recompense to which Mr. Fry objected.

Mr. FRY interposed by saying that he considered the admirable services which the Directors had rendered to the Company had been adequately rewarded by the £800 a year which they had drawn.

The CHAIRMAN said that one man might be very well rewarded with 1s. a day where another man would be badly paid with 10s. a day.

Captain PAVY pointed out that a great deal of work had been done by the Directors at one period of the Company's existence for which they had received no pay whatever, and that £6,000, having regard to the £400,000 of capital of the Company, which was greatly improved by what they proposed to do, did not amount to more than 1½ per cent. commission on the transaction.

The SOLICITOR said that the agreement had been carefully prepared by Mr. Kirby, of the Chancery bar, and he could assure the shareholders that they would incur no further responsibility by accepting the agreement.

The CHAIRMAN reminded the meeting that a similar resolution was unanimously adopted at the meeting of the Western and Brazilian Company the previous day, and repeated his opinion that in the interest of the shareholders of both companies the agreement would be of permanent advantage.

The resolution was then put to the meeting and carried, Mr. Griffith alone dissenting.

On the motion of Mr. YOUNG, seconded by Mr. GRIFFITH, a vote of thanks was cordially passed to the Chairman and Directors.

Digitized by Google

The CHAIRMAN, in acknowledging the compliment, said that he was sure he expressed the opinion of those who worked with him in bringing their feeble child into a state of manly existence when he said that they would rather have kept that child at home for a time, but seeing that it was better for its interests to go into a wider sphere, they were constrained to part with it. At the same time, they hoped to have a *souvenir* of its existence.

Indo-European Telegraph Company (Limited).

The twenty-first ordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, on Monday, the 30th ult., Colonel James Holland presiding.

The CHAIRMAN: Gentlemen, I beg to declare the meeting duly constituted, and I will call upon our Managing Director to read the notice calling the meeting.

Mr. W. ANDREWS (Managing Director) read the notice.

The seal of the Company was then affixed to the register of shareholders.

The CHAIRMAN: With regard to the report, I presume, gentlemen, you will take it as read.

The report and accounts were taken as read.

The CHAIRMAN: Gentlemen, these accounts call for very few observations. The revenue is just about the same, namely, £104,290, compared with £104,583. But that does not exhaust the matter, because although the total receipt is the same, it is not quite made up of the same parts. The Indian messages contributed between £6,000 and £7,000 less, and it is a discouraging fact that this traffic, at the reduced rates, ever since the reduction was made, has not reached its former amount, and at the present time still seems inelastic and disappointing. In fact, wherever the reduction of tariff was applied the same unsatisfactory result has happened as far as this Company is concerned. The Company's revenue has, however, fortunately been made up where the Company made no reduction, and by new sources of traffic already reported upon in the proceedings for the year 1886. There is really nothing more to be said with regard to the revenue. As regards the expenses, there is again a considerable decrease, which mainly consists of three items—stationery £472, agency and general expenses £495, and maintenance £1,119. All these are fluctuating items, and next year they may take a turn the other way. The increases are only £359 spread over several items, and are not worth analysis, the net result of the whole being a decreased outlay of £2,152. 12s. 5d. In pursuance of the policy you have approved for some time past we have added £10,000 out of revenue to the reserve fund, which now stands at £102,463, and looking around us we must admit that the provision is only ordinarily prudent. I think, gentlemen, you will agree with that. We are carrying forward a rather larger balance, so should the current year's expenses be somewhat more there is a nest-egg to meet it, and to keep the accounts from fluctuating as nearly as we can. We are believers in a good, steady, regular state of things if arrangements can be made to secure them. Our reserve fund investments, I may tell you, which now stand in our books at £102,463, if sold at last week's prices would fetch about £110,775, showing an increased value of 8$\frac{1}{10}$th per cent. Going into detail a little, the maintenance is very low, without anything having been neglected. But here again the shareholders must be cautioned that at a short notice a larger outlay may have to be made, and that the present figures must by no means be taken as the standard of regular maintenance outlays. The alterations and improvements happen to be very limited this year. The Company's line is in very good order, and has been so throughout the year. The shareholders will have seen by the report that the duplex system has been applied to work either the wire in Reuter's cable or that in the German Union cable between London and Emden. These apparatus were supplied by Messrs. Siemens, and, like all the other work they undertake, were a model of manufacture, and they continue to give perfect satisfaction. They have proved very useful too, and fully justify the prudence of the Company in providing them, for on the breakage of one of the cables the Company has been enabled to do its work practically without delay. Of course, when both cables were in working order the duplex has no work to do. The provision is made to guard against accident. The Company has always endeavoured to keep the system in advance of all requirements of the traffic. There is really nothing further to say, except to move that the report and accounts now submitted be received and adopted, and that a dividend be and is hereby declared for the half-year ended 31st December, 1887, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent. for the year.

Mr. J. HERBERT TRITTON: I second that.

The CHAIRMAN: Gentlemen, before putting it to the meeting, I will wait and hear if any gentleman has anything to ask on the subject of the report.

Mr. JACKSON: I should like to ask whether the Directors have any limit with regard to the reserve fund, and as to what amount they will consider to be satisfactory. I am not expressing any opinion upon the policy, but I should like to know, if it is not wrong to state it, if you will tell us what is the limit which, in the opinion of the Board, we should remain at with regard to the reserve fund. I see £10,000 is placed to it this year, so it is now nearly 25 per cent. of the whole capital, and it is a satisfactory reserve fund to meet all the requirements of business. I think a reserve fund is rather an evil than a good when it reaches too high a point. I think we are entitled to the profits which are made beyond this point; we can deal with them, perhaps, more satisfactorily in our pockets than the Directors can by investing it at the low rate of interest which they can get on the securities they hold.

The CHAIRMAN: Gentlemen, that question of the amount of the reserve fund is one which does not come upon us by surprise. It is one which we have fully and frequently discussed amongst ourselves, and I quite agree with the gentleman who has just spoken that 25 per cent. is, as an ordinary rule, a very fair amount of reserve fund. But there are special difficulties connected with this Company which induce us to consider we have not yet fully reached the amount which the reserve fund should show. We all know, it is no secret, for you have only to open a daily paper, and you will see how war is threatening in many parts of Europe. Were war to occur we should be shut up, for Germany and Russia, and Russia, most probably, would be closed to us. Therefore, as far as we can see our way at present, we cannot fix upon any specific amount. All we can say is that we hope the war crisis may be removed, and trade recover its wonted elasticity, and then we may be able to divide a larger amount amongst the shareholders. At the same time I must say that 10 per cent. free of income-tax, and an addition of £10,000 to the reserve fund—which, although it does not go immediately into your breeches pockets, adds very considerably to the value of the shares in the market—is not an inconsiderable amount of dividend. All I can say is that the Directors are anxious to divide more, but as prudent men they must be allowed to exercise their judgment as to the time when the limitation of the reserve fund can occur. I hope that expression of opinion will be satisfactory. I will ask those gentlemen who are in favour of the proposition which I have laid before them, and which has been seconded by Mr. Tritton, to be good enough to hold up their hands.

The resolution for the adoption of the report and accounts was then put and carried.

The CHAIRMAN: I have now, gentlemen, to state that in accordance with the provisions of the Articles of Association, two Directors retire by rotation, namely, Mr. H. Weaver and Mr. A. Delbrück, and I move

"*That Mr. Weaver and Mr. Delbrück be and are hereby re-elected Directors of the Company.*"

Major-General G. B. TREMENHEERE, R.E.: I second that.

The CHAIRMAN: When Mr. Weaver's name is put before you for re-election, it is only just for me to say that we are all well pleased to know that he will continue to give his services to the Board.

The resolution was carried.

Mr. WEAVER: I have to thank you for re-electing me, and I beg to thank the Chairman for the very handsome way in which he has put the proposition.

The CHAIRMAN: I have to state that Messrs. C. F. Kemp, Ford and Co., the Company's auditors, retire by rotation, and offer themselves for re-election.

Mr. STEFFEN: I have pleasure in moving

"*That Messrs. Kemp, Ford and Co. be re-elected auditors for the ensuing year.*"

Mr. JACKSON: I have pleasure in seconding that.

The resolution was put and carried.

The CHAIRMAN: That, gentlemen, concludes the business of the meeting. I would only like to add one or two words. At most of our meetings—all, I think, for years past—it has been my good fortune to be able to propose a special vote of thanks to the management of this Company, I mean the executive management subordinate to the Directors. My friend, Mr. Andrews, you all know, and anything more from me with regard to his merits would be mere superfluity, but Mr. Andrews has managed to raise a body of gentlemen without whom even his talents would hardly avail us. The establishment originally was fixed, and I think most of the men in it were brought in by Mr. Weaver at the beginning of the Company. Mr. Andrews has continued with these gentlemen, and it is owing to the ability, industry and integrity of the staff generally that we have become so flourishing. I see before me two of the leading members of the staff, Mr. Moll, the accountant and secretary, and Mr. Pagenkopf, our chief clerk. With both of these gentlemen we are frequently brought into communication, and I may say better officers no company is blessed with. We have others, not here, to whom I may allude specially. I allude to the gentleman who superintends the maintenance of the line, Mr. Guenzel, and Mr. Nelson, our chief officer in Persia—a very trustworthy and valuable man, and I beg to ask you, gentlemen, to concur with me in a vote of thanks to Mr. Moll and the staff of the Company for their good services during the year.

Mr. STEFFEN: I have much pleasure in seconding that. I know great responsibility rests upon the executive and upon the officials of a company like the present. There is a large amount of work to be done, and the result is shown in the efficiency with which the work is carried out.

The resolution was put and carried.

Mr. MOLL: On behalf of myself and the other members of the staff I beg to thank you most heartily for the very kind way in which you have alluded to us. Our services have always been appreciated by the Directors and therefore as long as I and others are connected with the Company we will continue to do our best.

The CHAIRMAN: Gentlemen, the business of the meeting is concluded.

Mr. JACKSON: I beg to move a vote of thanks to our honourable Chairman. It is gratifying to receive a dividend of 10 per cent. There are other companies in which it is impossible, I am afraid, to hope for half that amount. I hope, sir, your life may long be spared to conduct, as successfully as it has been conducted hitherto, this Company. It is certainly a great satisfaction to shareholders to think that there is one Company of this kind which is paying 10 per cent. I have great pleasure in proposing a vote of thanks to Col. Holland for presiding, and for the services which he has rendered to the Company for so long a period.

Mr. STEFFEN: I have much pleasure in seconding that.

The resolution was carried.

The CHAIRMAN: Gentlemen, I thank you for your kind expressions, and I hope, as years go on, although I may not look forward to presiding on many future occasions, the Company may still go on and prosper as it has done.

The proceedings then terminated.

The Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of the shareholders in this Company was held in the Cannon-street Hotel on Thursday, to elect two additional Directors, and to fix the remuneration of the Board. Mr. Hugh Watt, M.P., the Chairman, presided.

The SECRETARY having read the notice calling the meeting,

Mr. GREIG asked under what clause of the Articles of Association the meeting had been called.

The CHAIRMAN replied that it was under Article 43, and as he had thought the question would be raised, they were prepared with an opinion, which the solicitor would read, whereby, even admitting—which he did not—that he had convened the meeting, he had the power to do so.

The SOLICITOR then read the decision of Lord Justice Mellish in a case (M'Dougal *v.* Gardner) that came before his lordship, the general effect of which was to establish the right of directors when any grave irregularity in the management of a company occurred, or when any dispute arose, to call an extraordinary general meeting of the shareholders.

Mr. GREIG pointed out, however, that the cases were not on all fours, because in the present instance nothing was disputed, and the meeting had been summoned on the responsibility of one Director, and therefore, as he maintained, illegally.

Mr. KLENCK pointed out that the first paragraph in the circular sent out by the Chairman calling the meeting said:—"A wish having been expressed by the general body of shareholders at a recent annual meeting that the Board of Directors should be strengthened," &c., and went on to challenge the Chairman to give the slightest proof of the expression of that wish. At the last meeting a resolution was carried to the effect "That sixteen of the largest shareholders, or as many of them as will agree to act in conjunction with the present committee, be appointed as a committee to report to the shareholders as to what is best to be done in the interests of the company, and to take the earliest opportunity to submit the same to the shareholders, five of such shareholders to form a quorum." In the face of that resolution, the Secretary promised immediately to communicate with sixteen of the largest shareholders, which he had not done. Instead of that, the circular signed by the Chairman had been sent to some of the shareholders—he said some because he had received a large number of communications from shareholders saying that they had not received it—calling this meeting, which he, therefore, considered to be illegal.

Mr. JOHN NEWTON also stated that the decision of the learned judge just quoted did not apply to the present case.

The CHAIRMAN said it might facilitate matters if they would content themselves to vote on the issue as to whether the meeting was legal or not (No, no). He denied altogether the imputation that they had not communicated with the largest shareholders, because he took care the very night after the last meeting to consult with a number of them. (Voices: "How many?" and "Name them.")

Mr. KLENCK, amid a scene of uproar, then moved that the names of the sixteen largest shareholders, or such shareholders as had been communicated with, be given to the meeting.

A SHAREHOLDER having seconded the motion,

The CHAIRMAN observed that whatever the meeting chose to do he had sufficient proxies to carry the motion he would propose. (Voices: "No, no; it is an illegal meeting.") He had already put the matter in the hands of a solicitor, and he intended prosecuting the committee of five shareholders that had been appointed.

Mr. GREIG: It does not matter, since Mr. Watt loses every action at law he takes up (laughter).

The CHAIRMAN said he was quite sure he would not lose this one.

Mr. KLENCK said there was a motion before the meeting, and he called upon the Chairman to put it.

The CHAIRMAN said Mr. Klenck held 50 shares, and Mr. Greig 100, while he (the Chairman) held between 8,000 and 9,000, and he would move an amendment to Mr. Klenck's motion.

Mr. GRIFFITH amid uproar endeavoured to remind the shareholders that at an extraordinary meeting the business must be confined to the resolution which it was called to consider, whereupon loud cries were raised that the meeting was illegally convened.

Mr. KLENCK and other shareholders insisted upon the solicitor to the company (Mr. Hawes) stating definitely whether it was a legal meeting or not.

The SOLICITOR said: In my opinion it is the best legal meeting we could have (laughter and cries of "Yes, or no.") In my opinion it is a legal meeting under the circumstances (renewed laughter).

Mr. JOHN NEWTON asked how one Director could call the meeting seeing that the other two members had left the Board.

The CHAIRMAN observed that the meeting was assuming that he called them together, whereas Mr. Brown (a Director) assented to his course of procedure. What he had said at the last meeting was that he would not interfere in any way with the *status quo* of the Board. He would not himself decide the question as between Mr. Brown and Mr. Swaby, because he felt he would occupy an invidious position if he did so. The result was that he had gone on the assumption that Mr. Brown and Mr. Swaby were still Directors. (A Voice: "That is too lovely;" and laughter.)

A SHAREHOLDER asked whether Mr. Swaby's resignation had not been accepted at a recent Board meeting.

The CHAIRMAN replied in the negative, but declined to enter upon the question (laughter and uproar). Certainly Mr. Brown's resignation was not accepted. He maintained, in opposition to what had been insinuated, that Mr. Brown was still a qualified Director.

After some remarks from Mr. JOHN NEWTON, in which he strongly protested that the meeting was illegally convened,

The CHAIRMAN asked the meeting to vote upon the question, a request which was immediately responded to by loud cries of "No." Under these circumstances he would ask permission to make a few remarks. He thought that every member of the committee and every gentleman present must agree with him that the Company at the present time was in a most anomalous position. So far back as not only the last general meeting in March, but the year before, he had intimated to the shareholders that as soon as arrangements were completed for carrying on the Company, he would resign his active connection with the Company. He wished to repeat to-day that as soon as matters were in good ship-shape he wanted to carry out that intention (hear, hear). His reason for that decision was mainly based upon his physician's opinion owing to a recent illness that he had had. He had no wish to remain as a Director in the Company longer than the moment when arrangements could be made for carrying on the business satisfactorily. Although they were unable to declare a dividend last year, he could assure them that the Directors had had harder work last year than in previous years, and the cause of that was attributable simply to the fact that the Weston machine could not be manufactured so cheaply as two other machines that were thrown upon the market during the last twelve months, and they had lost a good deal of business in consequence; and finding that they were losing ground in the matter of profits, he thought it was extremely desirable that they should have additional Directors, and if the shareholders put forward two good names, let it not be thought for a moment that he wanted to oppose their choice. On the contrary, he would be very glad to welcome them, although he had received an overwhelming number of proxies, whereby he could carry any resolution he put to the meeting ("No, no"). At the same time, he would not use those proxies if the shareholders ruled that the meeting was irregular, and he would also like to add that he did not ask for the proxies, they were sent spontaneously (laughter). He considered it desirable to call this meeting in the interests of the Company to extricate them from the very disagreeable position in which they were placed. He did not do so with any sinister motive, for he had already told them that he meant to resign (hear, hear). He had done more for the Company than any man had done for any other electrical company in England (laughter). He had paid £9,500 in dividends, and all the capital that the general public had subscribed had been £4,500. The Company three months ago occupied a good position, and he could have told them that it occupied that day a great deal better position than they seemed to imagine; but as they had declined to hear him, he would waive the matter. He stood to lose between £4,000 and £5,000 by the Company, and although he was willing to resign his position, as a business man he was not going to throw away his stock for nothing. But he would point out that since these meetings began the shares had gone down 1s. 6d., and afterwards 1s., and if they were to be continued the property would go down to nothing at all. If the committee or anybody else thought they could bring the shares up to 10s, why did they not send in nominations for the Board?

Mr. GREIG said there had not been time.

Mr. NEWTON observed that there had really been no committee.

[At this point the proceedings became exceedingly noisy, several shareholders attempting to speak at once.]

The CHAIRMAN, continuing, said he held a substantial stake in the Company, and whether he had an official connection with it or not he would always do everything he could to advance its interests. He had originally saved it from bankruptcy (oh). The gentlemen who said "Oh" could not be old shareholders, or they would know the facts. When he took over the Company 6d. could not be got for the shares. They knew very well that when Admiral Inglefield left the Board the shares went to almost nothing.

A SHAREHOLDER maintained that they were at 13s.

The CHAIRMAN: Then why did you not sell? (laughter).

Mr. MARKS said that no business could be transacted at the meeting, because he held in his hand the opinion of an eminent counsel (Mr. Chadwyck Healey) which said that any such business could be opposed by any individual shareholder.

The CHAIRMAN, after some further discussion, said that in order to simplify matters, if it was the wish of the shareholders that no meeting should be held, he would not stand in the way. All that he could say was that he regretted it, because the meeting was convened in the interests of the Company ("No, no"). To him it was a matter of no importance whom they appointed as Directors. He thought, however, that if, say, two Directors had been elected to act in conjunction with the committee, they would have arrived sooner at a *modus vivendi*. There would have then been a Board that would have secured contracts in the lighting of mansions, and so on—a branch of business which had not been much cultivated. With that object in view, he had been about to take upon himself to introduce one gentleman to their notice. He had been trying to get one or two of the most competent electrical and commercial gentlemen to take up the conduct of the Company, and he thought he had secured one of great ability, regarding whom his friend, Mr. W. H. Preece, and other authorities, had emphatically said that he would have been a great acquisition to the Company. And the proposal he (the speaker) would have made was this, that he would have taken upon himself to make a provisional arrangement with that gentleman, subject to confirmation, of course, by the new Board; but he found that the gentleman in question had been since engaged elsewhere, and what he wanted to point out now was that they would have arrived at some practical solution of their present difficult position if they had added two gentlemen to the directorate. If they did not accept that proposition the *status quo* remained, and the Company would be in a very anomalous and unsatisfactory position. They could not do any business at present. They had in view some large contracts—certainly one large one.

A SHAREHOLDER: Within the last few days?

The CHAIRMAN replied certainly within the last five weeks, and

Google

during the last week he had seen the people who asked for the tenders, and they said that they would not do anything until the matter now before the meeting was brought to an issue. He did, therefore, think that the appointment of two gentlemenn would be an advantage, but if the meeting was unanimous that the proceedings were irregular, he would not press the matter (hear, hear). Mr. Healey was, no doubt, a well known counsel, but they had the opinion of another which was opposed to that of Mr. Healey, and the shareholders would have to decide as between these conflicting views.

After some further animated discussion,

The CHAIRMAN declared the meeting dissolved.

An informal meeting of the shareholders was afterwards held, Mr. Klenck presiding, but the proceedings were strictly private.

Submarine Cables Trust.

Report of the Trustees to the seventeenth ordinary annual meeting of the certificate holders, to be held at the offices of the Trust, No. 50, Old Broad-street, London, on the 8th inst., at 2 o'clock :—

2. The revenue for this period, including the balance brought from the prevous accounts, viz., £95. 2s. 2d., amounted to £18,044. 0s. 6d.

3. The trustees regret that the Atlantic Cables competition referred to at the last annual meeting of the certificate holders still continues, and that, in consequence of the small return from their investment in Anglo-American Telegraph Stock, they are unable to meet the coupons of the Trust in full as they become due.

4. The balance of £1. 10s. which was left outstanding on the coupons due on April 15th, 1887, was paid on October 15th last, and the coupons which became due on October 15th, 1887, were liquidated on April 16th, 1888.

5. The expenses of the Trust amounted to £1,381. 5s. 1d., and the payments on account of the coupons to £15,214. 10s., together £16,595 15s. 1d., leaving a balance of £1,448 5s. 5d. to be carried forward. This balance is equal to 8s. 6d. per cent., which the Trustees propose to pay to the certificate holders, with a further amount to be taken from the current year's revenue, as soon as they have sufficient available funds to make a substantial payment on account of the overdue April coupons.

6. A table showing the original and present investments of the Trust is appended to the report.

7. The meeting will have to elect two auditors for the current year ; Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election.

The Brazilian Submarine Telegraph Company, (Limited).

Report of the Directors for the half-year ended 31st December, 1887, to be submitted to the twenty-ninth ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on the 9th inst., at 12 o'clock :—

The revenue for this period amounted to £102,594. 9s. 8d., and the working expenses to £12 812. 15s. 8d. After providing £12,880 for debenture interest and sinking fund, and £1,918. 1s. 9d for income-tax, there remains a balance of £74,983. 12s. 3d. ; to this is added £1,932. 12s. 3d. brought forward from 30th June last, making a total of £76,916. 4s. 6d. First and second interim dividends amounting to £39,000 have been paid, and £25,000 transferred to the reserve fund, leaving the sum of £12,916. 4s. 6d. to be carried to the next account.

In accordance with the provisions for repayment of the first issue of debentures, dated 31st July, 1884, 139 bonds representing £13,900 were drawn on the 26th April last, for payment at par on 31st July next. This, with the previous drawing, will make a total repayment of £51,000, leaving a balance of £99,000 on the first issue of debentures.

The ss. "Britannia" of the Telegraph Construction Company was employed in January last in repairing the shore end of the Lisbon-Madeira 1884 cable, which had been damaged by a severe storm. Whilst the ship was at Madeira it was considered desirable to remove a fault which existed in the Madeira-St. Vincent cable of 1874. Several miles of entirely new cable have been laid, replacing old cable on bad ground, which might have proved a constant source of trouble in consequence of rocky bottom. The cable recovered in deep water during the operations was found, after being submerged 14 years, to be in excellent condition both as regards the iron sheathing and the core.

The various sections of the Company's line are in good working order, with the exception of the St. Vincent-Pernambuco 1874 cable, in which a fault appeared on the 11th ult. ; this, however, in no way intereferes with the regular transmission of traffic by that cable. The fault being in shallow water some 21 miles from Pernambuco, no difficulty is anticipated when it is considered advisable to remove it.

West Coast of America Telegraph Company (Limited).

Report of the Directors to be submitted to the eleventh ordinary general meeting to be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, the 9th inst., at 1 o'clock :—

The balance-sheet and revenue account show a gross income of £57,893. 9s. 9d. for the year ended 31st December, 1887, against £43,026. 13s. 1d. for the previous year. After deducting debenture interest and all other charges there remained a net profit of £23,114. 18s 1d. for the past year, as compared with £11,037. 3s. for the year 1886. Adding the amount of £776. 16s. 5d. brought forward, the total sum to be dealt with was £23,891. 14s. 6d. Out of this the following dividends have been paid:—In July, 1887, 4s. per share, £6,000 ; in January, 1888, 6s. per share, £9,000 ; total, £15,000.

The Directors now recommend writing off £1,557. 15s. 3d. from the value of the repairing steamer "Retriever," thereby reducing her valuation in the books of the Company to £17,500, and to add £7,000 to the reserve fund, making the latter £27,000, which distribution will leave £333. 19s. 3d. to be carried forward.

The increased earnings of the Company are due to a large increase in the number of messages transmitted and—as far as the local traffic is concerned—to a small extent to an improvement in the rate of exchange.

The cables and repairing steamer are kept in perfect working order.

The members of the Board retiring by rotation are Mr. Alfred Marshall and Mr. Henry Roberts ; both are eligible, and offer themselves for re-election.

The auditor, Mr. J. Weiss, of Messrs. Turquand, Youngs and Co., retires, and is eligible for re-election.

NEW COMPANIES REGISTERED.

ASHWORTH BROTHERS AND COMPANY (LIMITED).—This company was registered on the 19th inst., with a capital of £10,000 in £10 shares, to carry on, at Manchester or elsewhere, the business of an electric light company in all branches, and to adopt an agreement of 13th ult., between Thomas Ashworth and Frederick King for acquiring a license of the patent right No. 4,081.
